Multiple tortfeasor issues cover cases where the loss is jointly caused by several people acting in a common purpose or not. A lot of examples illustrate these situations including accident law, environmental damage, product liability, etc. The law and economics literature has devoted much attention on these situations in order to understand the properties of different liability rules. Two levels of discussion should be distinguished: first, the negligence/strict liability debate, and second, the joint or no-joint liability rules meaning that the victim may get compensation back by any of the tortfeasors. The article surveys the most important results in law and economics and insists on the fact that multiple tortfeasor cases lead to paradoxes which challenge the very basis of the tort law and the economic rationality.

From One Defender to Several

At the very beginning, tort law has been one of the most promising fields in law and economics: Coase, Calabresi, and Posner were particularly interested in the efficiency of liability rules.

However, the economic basic model implied only one tortfeasor (Posner 1973; Coase 1960; Calabresi 1970). The scope of this model was limited and did not cover more complex cases where several tortfeasors jointly cause the harm suffered by the victim, what is called multiple tortfeasor issues. Sometimes, cases of multiple tortfeasors refer to harm due to a common purpose of several people. However, the scope of multiple tortfeasors is broader and covers also harm due to independent wrongdoers' behaviors. Many examples of multiple tortfeasors come in mind: accident law, environmental law, products liability, etc. the law and economics literature about multiple tortfeasor cases started at the beginning of the 1980s and does not necessarily converge on clear principles. The reason is that two levels of discussion are involved: the first is about the regime of liability (strict liability or negligence), the second about the joint or non-joint liability.

To handle with this complexity, legal scholars have fallen into the habit of forming their reasoning based on typologies to classify different cases (Hart and Honoré 1985; Landes and Posner 1980, 1983). The first case is simple: several tortfeasors independently act at the same time, and their joint behaviors simultaneously lead to harm (two polluters pouring toxic waste in a river). The second case is sequential: a first tortfeasor causes at time t_1 a first harm that is enhanced at time t_2 by another wrongdoer, etc. The third case covers the example of contribution from the victim which has participated to its own harm (e.g., because he has not taken sufficiently care level). The fourth case implies uncertain causation: harm occurred without knowing with certainty who is the true wrongdoer (two hunters shooting while only one bullet actually harms the victim). In the following, we focus on the third first cases, and we do not deal with uncertain causation (see the article ► “Causation” in the *Encyclopedia*).

These complex cases have been extensively studied by legal scholars (Hart and Honoré 1985; Wright 1985; Stapleton 2013) because they challenge the usual way to consider liability, causation, and torts. Indeed, imagine two people lighting a fire in a forest. Suppose that these two fires merge together and destroy the house of the

victim. In such a case of overdetermined causation, the “but for test” criterion advocated by the law is useless: each of the tortfeasors could escape from his responsibility by pretending that, without his own action, the harm would have occurred anyway. It would be unfair and inefficient to follow the black letter of the “but for test,” and these cases require other legal solutions.

From the economic point of view, these cases are also difficult to handle with. We will survey one of the most key elements of the findings of law and economics literature on this topic. First, we insist on the efficiency and incentives aspect. We also deal with the fairness of the sharing rules applied by judges to apportion damage. Then, we compare three rules from an economic perspective: several liability, joint and several liability, and channeling liability. Last, we conclude with dealing with some of the most striking paradoxes raised by multiple tortfeasor cases.

Incentives, Efficiency, and Fairness

As we will see, in many instances, multiple tortfeasor cases challenge the result of efficiency which holds for a simple one victim/one tortfeasor case. First, it is now well-known that one of the most important findings in law and economics is lost when several tortfeasors are implied. In a paper published in 1981 by Aivazian and Callen, and entitled “Coase Theorem and the Empty Core,” these authors take a simple example where two polluters cause harm to a victim. Under the general conditions of the Coase theorem – perfect delineation of property rights and zero transaction costs – the result of invariance and efficiency cannot be proved. The reason is that the core of the game may be empty meaning that there is no stable allocation which could emerge from negotiation: victim and tortfeasors negotiate again and again without any convergence of their offers.

In case of positive transaction costs, liability rules are studied to implement an efficient output in terms of care, activity, and actual harm (Shavell 2004). But when it comes to efficiency in cases of multiple tortfeasors, it is difficult to conciliate two principles: the principle that every tortfeasor should pay for the harm he is responsible

for and the fact that the total amount of compensatory damage be equal to the harm. Most of times, if principle 2 is followed, underdeterrence is expected. On the contrary, if principle 1 is followed, it requires implementing a sanction which is above the amount of harm. This result is easy to show in case of strict liability. Assume that two tortfeasors 1 and 2 cause harm to a victim. The objective function of social cost to be minimized is $x_1 + x_2 + p(x_1, x_2) \cdot h$, with x_1 the cost of care of 1, x_2 the cost of care of 2, h the amount of harm, and p the probability of harm. To induce optimal care, it would be necessary that each tortfeasor bears damage of h . This is impossible insofar as h will be split among the two liable tortfeasors (usually, the compensatory damage is equal to harm, no more, no less). Other authors have elaborated on this issue by providing alternative rules. For example, Miceli and Segerson imagine a rule where each tortfeasor is responsible for the marginal damage that it causes. In that case, efficiency is achievable, but it requires that the total amount jointly paid by tortfeasors be above the loss caused. Miceli and Segerson consider that a mixed system requiring on the one hand, the recovery of the loss to the victim and, on the other hand, a fine to be paid to the state could achieve efficient incentives (Miceli and Segerson 1991; Miceli 1997).

While under strict liability, tortfeasors are threatened to pay less damage than required by efficiency; under negligence rule, incentives are different. If the efficient care standard (x_1^*, x_2^*) is implemented by the law, a tortfeasor will not be held responsible if his level of care is above the efficient level. The best way to analyze the behaviors of tortfeasors is to use game theory and to wonder whether the equilibrium of the game exists and reaches social efficiency. If tortfeasor 1 has chosen x_1^* , the best response of tortfeasor 2 is to choose the efficient level x_2^* . If not, he would pay for the entire damage. The situation is symmetric for the agent 1. As Shavell states, "The superiority of the negligence rule has to do with the fact that, by the nature of the negligence rule, each party is threatened with damages equal to the *entire* harm h when other parties act optimally; whereas under strict liability, each

party is threatened with a lesser amount" (Shavell 2007). This result holds when tortfeasors are jointly liable (they expect to pay for the entire loss) but does not hold in case of several liability where they would expect to bear only a share of the loss (Kornhauser and Revesz 1989). In the previous paragraphs, we have implicitly supposed that all the tortfeasors are solvable. In case of insolvency, the previous results may be altered, and we will focus on this issue in part III.

In a different perspective, it is possible to have a more fairness-oriented point of view and be interested in the contribution of tortfeasors. The idea is to have a scheme of payment which is in line with the causal contribution of each tortfeasor. Some legal scholars have elaborated on this idea of causal contribution (Stapleton 2013). In law and economics, comparative causation is such a rule (Parisi and Singh 2010). This idea dates back to Calabresi for whom negligence has an unexpected effect to promote a one or no liability. He suggests splitting the loss among parties following their causal contribution. Parisi and Singh follow this argument and have carefully studied the properties of a causal contribution rule mixed with a negligence rule. They show that such a rule has interesting properties in terms of optimal care level and optimal activity level and consider that it is a fair and equitable rule. In a different perspective focused on ex post issues, other scholars use cooperative game theory and consider that the Shapley value is a good candidate to provide an evaluation of the contribution of each tortfeasor involved in the case of indivisible harm. Moreover, the Shapley value has axiomatic properties interesting for the law, and it could be shown that most of principles advocated in the *Restatement of Tort* (American Law Institute 2012) in the USA to apportion damage are close to the elementary principles of the Shapley value (Ferey and Dehez 2016a).

Several, Joint and Several, and Channeling Liabilities

Even though it was possible to clearly apportion harm among tortfeasors, a separate issue raises about how the victim could trigger responsibility against each of them. In most countries, three

rules are implemented by the law: several liability, joint and several liability, and channeling liability (Faure 2016). Several liability states that each tortfeasor is responsible for his share and the victim has a separate claim against each of them but only for their respective shares. Several liability has two consequences: first, the victim has to bear the costs of several suits to recover all the compensation of his harm from all the tortfeasors separately; second, the risk of insolvency of one of the tortfeasors is bear by the victim.

Several and joint liability is different: the victim has a claim for the entire compensatory amount against any of the tortfeasors and gets all its recovery damages back from him. Then, in most of legal systems, the tortfeasor who has compensated the victim has a claim against the other tortfeasors to get their respective shares of responsibility back. Joint and several liability has two consequences: first, litigation costs are decreasing for the victim (and increasing for the defender); second, it is expected that the victim will choose the most wealthy defender to get its recovery back (following a deep pocket argument), and the risk of insolvency is bear by the solvable defender, not by the victim. A lot of fields in torts around the world are organized under a joint and several liability. In Europe, for example, the *European Principles of Tort Law* (see European Group on Tort Law 2005) mainly advocate joint and several liability.

Third, channeling liability indicates ex ante who among the potential tortfeasors is fully responsible and most of times without any claim against the others. Channeling liability is implemented by some international conventions. For example, the *Paris Convention on Nuclear Liability* has decided that nuclear liability is channeled to operators. The relative properties of the three rules have been extensively discussed in the law and economics literature which focus on four main topics: litigation costs, incentives, insolvency, and insurance (Faure 2016). We could add that the choice of one of the three rules (several, joint and several, or channeling liability) may be influenced by pressure groups without any global efficiency concerns.

Regarding litigation costs, the three rules are different. Channeling liability makes recovery easier for the victim: the identity of the party to be sued is certain, and only one lawsuit has to be filed. On the contrary, several liability seems costly for the victim who is required to pay for as much suits as the number of tortfeasors. Joint and several liability is intermediate: the litigation costs for the victim to get compensation back is relatively low but increase for the deep pocket tortfeasor which is required to pay for lawsuits against the other tortfeasors. And it could be expected that enforcement of the law will be more effective if litigation costs are low for the victim.

Regarding insolvency, the three rules have also different properties. The insolvency issue arises when at least one tortfeasor is not able to pay his share of damage back. Full solvency of tortfeasors seems to be a strong hypothesis which does not hold in many cases, and insolvency should be expected due to the high amounts that firms have to pay. First is the distributive issue: who should bear the risk of insolvency, the victim or the other tortfeasors? Most of legal systems consider that it is fair enough to avoid the undercompensation of the victim due to insolvency. The risk of non-recovery is shifted to the solvable tortfeasor.

This point has consequences on incentives. Under joint and several liability with insolvent actors and channeling liability, a tortfeasor may be asked to pay beyond his own share without any possibility of recovery from other defenders. The consequences on the level of care and the level of activity taken by the parties are not clear. First, the insolvent tortfeasor does not take into account the risks he created above the total value of its assets. Up to a certain point, he is underdeterred. Second, the solvent tortfeasor may be aware of this insolvency and internalizes the fact that, in case of several and joint liability, he should pay for the other's share. The main effect is on the activity level which may be reduced or eliminated to avoid any liability. This effect is called the crushing effect of liability. Third, the opposite effect may also happen. Intuitively, the reasoning insists on the fact that, in case of limited solvency, liability rule has no deterrent effect above a certain level

anymore (it has the same effect as statutory caps on liability). Up to a certain point, a domino effect occurs: the share of the insolvent tortfeasor to be paid by the remaining solvable actor is so huge that liability has no deterrent effect anymore on the solvent agent (Kornhauser and Revesz 1989). Lastly, a monitoring policy may be expected from parties: a tortfeasor who knows that he is likely to pay for others has an incentive to control and monitor other parties to be sure that they decide optimal levels of care and/or activity. However, in some cases, a defender has no way to monitor the level of care taken by other.

The three rules have strong consequences on insurance markets. The fact that one tortfeasor pays more than his share means that its insurance company is not able to calculate a risk premium anymore. Virtually, the insurance company will guarantee all the losses caused by all the participants of the market. Here is the risk of a crushing effect on the insurance market. The argument could be mitigated by the diversification of risks: It is unlikely that the same insurance company be concerned by all the cases implying multiple tortfeasors (Faure 2016).

Paradoxes

We would like to conclude by several paradoxes raised by multiple tortfeasor cases which illustrate significant challenges: overdetermined causation, aggregation issues, and offsetting benefits.

A first series of paradoxes is well-known by legal scholars: the overdetermined cases (Hart and Honoré 1985). It is the case of the two fires merging and destroying a property. In that cases, the black letters of the classical criterion of causation leads to irrational results. That is why other views on causation are proposed by legal scholars like the NESS test – necessary element of a sufficient test – (Wright 1985) or the causal contributions (Stapleton 2013). These criteria of causation may be modeled in an economic framework (Ferey and Dehez 2016b) and explain the reasons of the paradoxes.

Implying several people, multiple tortfeasor cases lead also to aggregation puzzles. In a recent paper, Porat and Posner have provided a general framework to capture aggregation issues. Regarding torts, they insist on the general consequences

of the burden of proof. As many scholars, they consider that preponderance of evidences rule may be translated in terms of a probability superior to 50%. Imagine that a victim suffers two harms: the first one is due to an error of the surgeon of an hospital with a probability of 0,6 (event A) and a second one by a nurse of the same hospital (event B) with a probability of 0,6 (Porat and Posner 2012). Then, the victim files a lawsuit against the hospital for the two harms. Without aggregation, liability of the hospital will be held for the two harms because the probability of event A and of event B is superior to 0,5. However, it could be said that the probability that the hospital be responsible jointly for the two harms is only of 0,36 ($0,6 \times 0,6$) which is the probability of the conjunction of the two events. The paradox raises from the fact that the preponderance of evidence leads to consider that the hospital should not be held responsible for the two harms. Such paradoxes are particularly interesting regarding multiple tortfeasors. A general typology of all the different types of aggregation issues is provided in Porat and Posner (2012).

The third type of paradox is implied by what is called “offsetting benefit”. Offsetting benefit issues are broader than multiple tortfeasor issues, but they are particularly concerned with. Porat and Posner have extensively dealt with these cases (Porat and Posner 2014). A simple example of the problem is the following. Imagine a victim driving his car to reach the airport where he has to take a flight. On the road to the airport, he is harmed by a wrongdoer and cannot take his plane. It then appears that the plane crashes. Following strict causation reasoning, it could be said that the wrongdoer has caused an injury but has also saved the life of the victim. Should we consider that the benefits due to the accident has to be taken account in the calculus of the compensatory damage? In this example, the victim could even compensate the tortfeasor due to the behavior of a potential second tortfeasor. There are different ways to solve these types of cases, and Porat and Posner provide some elementary principles to guide courts.

To conclude, it is clear that a lot needs to be done to better understand all the aspects of

multiple tortfeasors issues. We have shown how the difficulties of this topic are both philosophical, legal, and technical, implying different aspects in terms of efficiency and fairness and let a room open for political choices.

Music Royalty Rates for Different Business Models: Lindahl Pricing and Nash Bargaining

Definition

The Lindahl Equilibrium and Nash Bargaining Solution serve as useful and complementary analytical tools that provide guiding principles for the determination of appropriate music royalty rates in the current digital era, which poses challenges and pitfalls for the pricing of information goods, most notably musical works and sound recordings.

Introduction

We discuss the economic concepts of Lindahl Equilibrium and Nash Bargaining Solution as useful and complementary analytical tools in the context of the current digital era, which poses challenges and pitfalls for the pricing of information goods, most notably musical works and sound recordings. These concepts of modern economic theory are more than ever useful, even required, to provide the guiding principles underlying the determination of appropriate music royalty rates.

There is a general agreement between rightsholders, copyright users, and tariff-setting organizations that tariffs should be “fair and equitable” to both rightsholders and users and reflect the value or benefits the users derive from copyrighted works.

From an economic perspective, a “fair and equitable” level of transactions and compensation is equivalent to the level of transactions and compensation that emerges from a competitive market where willing buyers and willing sellers freely negotiate and settle transactions. Such willing buyers and sellers are assumed to be price-takers or devoid of market power. They would agree on transactions up to the point where the marginal value of an additional transaction for buyers is equal to the marginal cost of that additional transaction for sellers. From that perspective, the tariff to be paid for the use of copyrighted musical works and sound recordings should be based on the amount that users would willingly pay if they were transacting in a well-functioning competitive market.

The Copyright Board of Canada, the US Copyright Royalty Board, and other tariff-setting institutions represent a surrogate for a competitive market where the price that would prevail for copyrighted works is determined, if such a market existed and operated efficiently. To determine a competitive price for copyrighted works, these institutional bodies typically consider relevant proxies or indicators on buyers, sellers, prices of substitute products and services, industry characteristics, and virtual or simulated competitive processes such as auctions, etc. The challenges encountered in emulating a competitive market are numerous, some of the most salient being the fact that musical works and sound recordings are information goods and that digital technologies are profoundly changing the copyright landscape.

Information Goods and Digitization: Lindahl Pricing and Nash Bargaining

From an economic perspective, musical works and sound recordings are “information goods.” An information good is a good whose

consumption by one consumer does not prevent its consumption by others, a characteristic of “information” under different forms. In other words, once a musical work or sound recording is created, it can be “consumed” by all, as one person’s use of a musical work or sound recording does not prevent its simultaneous or subsequent use or consumption by someone else. See for example, Varian (1999) and Bakos et al. (1999).

Although related, the “information good” nature of musical works and sound recordings and the digitization of music are two different but equally challenging factors in the current copyright setting. The first one relates to the indefinite sustainability of a product, as one’s consumption does not destroy the consumed unit, which remains fully and unabatedly available for everyone else now and in the future, hence making musical works and sound recordings akin to non-decaying assets. The second one relates to the much-reduced dissemination cost of that product or asset in a digital context. See Boyer (2018).

In such a context, striking the right balance between creators’ rights and users’ interests is a difficult and multifaceted endeavor for different reasons: (a) musical as well as other cultural products such as literary works are costly to create and (b) digital technologies have significantly reduced the marginal cost of dissemination of those copyrighted works.

Due to these factors, pricing copyrighted musical works and sound recordings, with the objective of achieving proper compensation for creators, i.e., a creators’ right, *and* maximal dissemination of such goods, i.e., a users’ right, requires a move away from the usual analysis aimed at setting a product’s price equal to its marginal cost. Setting a price equal to marginal cost would clearly not enable the proper, fair, or competitive compensation of sellers, producers, and creators. Considering that musical works and sound recordings are permanent assets rather than perishable consumption goods raises questions regarding the proper price concepts to use: the same unit can be sold and resold infinitely many times.

The determination of relevant copyright tariffs rests not so much on the cost of creation,

which underlies the supply function of new musical works and sound recordings, but rather on the value of such goods for the users. Indeed, the Copyright Board of Canada (2002) acknowledged that “the important notion in information industries [is that] pricing tends to be based on the value to the buyer, not on cost to produce.”

The supply function of musical works and sound recordings in the rightsholders’ collective repertoire (stock) is horizontally constant at a price p just above 0 (infinite price elasticity at $p = \varepsilon$). That is because the marginal cost, which underlies the supply function, is quasi-zero for the rightsholders: zero marginal cost of reproduction and dissemination and zero marginal opportunity cost, those musical works and sound recordings being resalable an indefinite number of times. Setting the tariff equal to this marginal cost would generate no revenue for the seller, here the rightsholders, thereby failing to meet a central objective of the copyright institution. Insofar as the compensation of rightsholders must come through transactions, not from public subsidies or grants, the setting of tariffs is cast in a second best economic framework.

In this context, the proper price equilibrium is the Lindahl (1958) equilibrium. It is a generalization of the competitive equilibrium for public or information goods, according to which, given a stock of musical works and sound recordings, different users pay for access to a relevant repertoire, prices equal, or proportional to their respective derived marginal values.

The notion of Lindahl pricing was developed to characterize both the optimal or efficient quantity of a public good and a way to finance its production cost. It requires that the price paid by a given buyer or user of a public (or information) good be positively linked to the value or the amount of satisfaction derived from the consumption of that public good, as everyone is assumed to consume, at least virtually, the whole good. The user deriving a greater (marginal) value from the same marginal unit would pay a higher price. As long as the sum of those prices is above the marginal cost, additional units should be produced. The efficient quantity and quality level are

reached when the sum of users’ marginal values (prices) is equal to the marginal cost. The Supreme Court of Canada has asked the Copyright Board of Canada to consider such analytic framework in setting tariffs.

Technological Neutrality

The Supreme Court of Canada, in its 2015 landmark decision introducing the principles of technological neutrality and balance, stated:

One element of just compensation is an appropriate share of the benefit that the user obtains by using reproductions of their copyright-protected work in the operation of the user’s technology. That just compensation must be valued, however, in accordance with the principle of technological neutrality. While highly unlikely, where users are deriving the same value from the use of reproductions of copyright-protected works using different technologies, technological neutrality implies that it would be improper to impose higher copyright-licensing costs on the user of one technology than would be imposed on the user of a different technology. To do so would privilege the interests of the rights holder to a greater degree in one technology over the other where there is no difference between the two in terms of the value each user derives from the reproductions.

The converse is also true. Where the user of one technology derives greater value from the use of reproductions of copyright-protected work than another user using reproductions of the copyright-protected work in a different technology, technological neutrality will imply that the copyright holder should be entitled to a larger royalty from the user who obtains such greater value. Simply put, it would not be technologically neutral to treat these two technologies as if they were deriving the same value from the reproductions. (Supreme Court of Canada 2015, paragraphs 70, 71)

The Supreme Court asked the Copyright Board to consider that if a user with a given technology derives more value from a product, say a repertoire of musical works and/or sound recordings assets, than another user with a different technology, the former user should pay more than the latter, even if both use the same repertoire. In other words, the two users would access the same asset at different prices.

The Supreme Court thus recognized that, for efficiency and fairness reasons, users with different business models may be subject to different

tariffs for access to the same stock of musical works and sound recordings. There is a direct link between technological neutrality and Lindahl principles for pricing information goods.

Applying Lindahl principles is arduous and full of potential pitfalls especially in the context of copyright royalties. First, determining the (marginal) values different users assign to an asset is challenging. Second, many tariffs are expressed as a proportion or percentage of an accounting base rather than as a price per unit.

Finding the (marginal) values different users attach to or are willing to pay for an asset could be achieved through simulated auctions. The Copyright Board has alluded to such auctions in its 2002 Digital Pay Audio Decision as follows: “The Board finds it useful to comment on the ‘simulated auction’ approach which was discussed at the hearing. This scenario calls for setting the price of music at what one would be willing to pay to acquire a monopoly over DPA. That approach must be set aside because it focuses again on profitability at the expense of all else. This being said, the exercise is not without merit, if only because it highlights the important notion that in information industries, pricing tends to be based on the value to the buyer, not on cost to produce” (p. 8).

Many tariffs are expressed as a proportion or percentage of an accounting base due to the challenging factors involved in pricing copyrighted works on a per unit basis. Expressing royalties as a percentage of an accounting base, such as the user’s revenues, serves different purposes. It allows for the following: (a) savings in transaction costs, including assessing and verifying copyright payments; (b) immunity to accounting manipulations if the rate base is well chosen and valid; and (c) risk-sharing between rightsholders and users as a whole because it may be difficult or impossible to know *ex ante* which user will be successful in turning profitable access to a stock of musical works and sound recordings. However, expressing royalty payments as a percentage of an accounting base does not provide any indication about the price of copyrighted work. This follows because a percentage is not a price.

A Percentage Is Not a Price

A major source of confusion in royalty rate setting is the trap of “considering a percentage as a price.” There is no reason to believe that the proper price to be paid for the same inputs, namely, the right to access a stock of musical works and sound recordings, would correspond to the same percentage of revenues irrespective of the characteristics of the underlying industries under consideration. In fact, using the same percentage will usually lead to subsidizing one industry at the expense of another because, under the economic law of one price, the same price for the same inputs used in two different industries will, in general, represent quite different percentages of the value of the industry outputs (or revenues). Moreover, Lindahl equilibrium calls for different prices for different users or consumers of the same good.

The following example can help illustrate why a percentage is not a price. Suppose an apartment in a low income housing project is valued at \$100,000. Suppose also an apartment of the same size and configuration in a high-income housing project is valued at \$1,000,000, i.e., ten times more. Then suppose that the same quantity and quality of paint is used for both apartments. As expected, the cost of painting the two apartments would be the same as the law of one price applies to the input market (i.e., paint). In economics, the law of one price states that similar products in the same market should sell at similar prices. Let us suppose that the actual cost of paint for the high value apartment is \$1,000, i.e., 0.1% of the value of the apartment. If one takes the 0.1% as the “price” of the paint to be paid for the low-value apartment, one would get a price in dollar terms of $0.1\% \times \$100,000 = \100 or one-tenth of the cost of the same amount and quality of paint used for painting the high-value apartment. In fact, the cost of paint expressed as a percentage of the value of the two apartments would be quite different: 1.0% for the low-value apartment and 0.1% for the high-value apartment, a difference by a factor of ten for the same quantity and quality of paint.

As we further discuss below, regulatory bodies responsible for setting royalties on the use of copyrighted works tend to avoid transferring

percentages from one industry to another without proper adjustments. In doing so, they aim to ensure that percentages reflect similar prices for the same rights.

Making those different percentages correspond to Lindahl prices and percentages requires additional adjustments.

Balance Between Rightsholders and Users

The Supreme Court of Canada has stated that achieving balance between the rights of creators and users requires the Copyright Board take both rights into account in the determination of royalty rates by considering “respective contributions of, on the one hand, the risks taken by the user and the investment made by the user, and on the other hand, the reproductions of the copyright-protected works to the value enjoyed by the user” (Supreme Court of Canada 2015, paragraph 75). The principle of balance is related to the economic concept of a bargaining game, which in turn is related to the concepts of competitive equilibrium and negotiated price.

A bargaining game is an analytical framework of game theory that seeks to model a situation in which there is a conflict of interest between different agents who have the opportunity to reach a mutually beneficial agreement but may nevertheless veto any agreement. When “there is more than one course of action more desirable than disagreement for all individuals but conflicting views over which course of action to pursue, then negotiations to resolve the conflict will take place” (Osborne and Rubinstein 1994, p. 117).

In this context, the framework of a bargaining game appears as a tool to model the negotiation process and to determine how different agents who contribute to the creation of a given surplus or value added can share such value among them. A solution to the bargaining game is a sharing formula that specifies what percentage of the total value added each agent receives at the end of the bargaining game. The total value to be shared, the agents’ outside options (i.e., alternative options in case they do not reach an

agreement, including the no-investment option), as well as their bargaining power all play a role in the determination of the solution.

John F. Nash Jr., the 1994 laureate of the Nobel Memorial Prize in Economic Sciences, proposed a solution to such a bargaining problem, known as the Nash Bargaining Solution (NBS). The NBS is derived from four axioms defined as desired or reasonable properties. Namely, the solution should be (Pareto) efficient, symmetric, immune to equivalent reformulations of players’ objectives, and immune to irrelevant alternatives. The efficiency property simply states that the solution should leave no money on the table. The symmetry property states that if two agents are in similar positions or have similar capacities to negotiate, they should be treated equally, that is, obtain “similar” shares of the pie. Given that each party is rational, well advised, and controls an essential input, each holds similar power to negotiate and veto any solution and therefore can be considered to be equally capable of negotiating and affecting the solution. The other two axioms are more technical and not developed here.

Nash shows that there is only one solution to the above bargaining problem (Osborne and Rubinstein 1994, p. 307). In other words, there is a unique sharing formula that satisfies the four axioms: once each agent is properly compensated for the cost it incurs to sit at the negotiation table, the residual monetary value would or should be shared 50-50 between the agents. Given the reasonableness of its axioms, the Nash bargaining solution (NBS) is a powerful result. It says that whatever the negotiations conduct and/or process, i.e., no matter how the negotiation is conducted, the expected ultimate end-point or result can only be the NBS. As mentioned above, the NBS is closely related to the concepts of competitive equilibrium (willing buyer, willing seller) and negotiated price, two concepts regularly referred to in hearings before tariff-setting organizations.

The balance required by the Canadian Supreme Court to be considered in rate-setting must be reached in a context where standard perfectly competitive conditions do not prevail. Regarding copyrighted musical works and sound recordings, a standard competitive market with

individual buyers and sellers with no market power and symmetric information does not generally exist. However, implicit negotiations can take place between representatives of the parties before a rate-setting body emulating a competitive framework and solution. A negotiated price would then be considered the solution of the bargaining game involving the different parties. Such negotiated prices are grounded in economics as accounting for (and therefore balancing) the relative contributions and alternate options of the parties involved in the negotiations. The Nash Bargaining Solutions of negotiations between different users and the rightsholders call, under the 50-50 rule, for different royalty payments for different users with different business models for packaging and transmitting or distributing music.

Hence, the principles of technological neutrality (Lindahl pricing) and balance of rights (Nash Bargaining) in the context of information goods require that different business models be charged different royalty rates for the same access to musical works and sound recordings. In other words, efficiency and fairness in royalty setting run against business model neutrality.

The Case of Digital Pay Audio and Commercial Radio in Canada

In Canada, payments for communication rights of musical works and sound recordings in the digital pay audio industry (DPA) as well as in the commercial radio industry (CR) are measured as percentages of a rate base (the total revenue of the user). In fact, the Copyright Board (CB) has at numerous times compared and used as proxies royalty rates expressed as percentages of revenues by carefully applying relevant adjustments to account for differences among the industries considered.

Applying the above reasoning to the CR and DPA industries, similar prices for the same access rights to the same repertoire of musical works and sound recordings, when expressed in percentage terms, will represent a higher percentage in the lower value added DPA industry, where the main input is music, than in the higher value added CR

industry, where musical works and sound recordings are one input among many including news, weather, or traffic reports and on-air personalities. In other words, similar prices would yield different percentages.

In its decision, the Supreme Court of Canada instructs the Board to consider that if a user, such as DPA services, derives more value from the product, say the repertoire of SOCAN Collective of authors and composers (musical works) and Re:Sound Collective of performers and makers (sound recordings) than another user, such as a CR operator, the former user should be asked “to pay more” than the latter.

In Canada, the commercial radio royalty rates for musical works and sound recordings are both 4.2% (before adjustments for repertoire) of the user’s revenues. Suggesting to increase the combined CR royalty rate of 8.4% to 10.6% for DPA on the basis that the latter uses 25% more music per given period, would clearly not satisfy the technological neutrality principle insofar as the DPA industry derives greater value from musical works and sound recordings relative to CR, which generates revenues from other programs.

One possibility would be to, first, derive the level of royalties generated by the 8.4% rule and, second, express it as a percentage of revenues generated by music only; indeed, the commercial radio industry depends less on music than the digital pay audio services industry. On average, music format radio stations broadcast music content during 80% of programming time and other content (news, survival programming, on-air personalities, or talk) during the remaining 20%, while DPA services play music 100% of the time, that is, 25% more. However, the CB has repeatedly expressed the view that on-air talent is more important than music to radio stations. In its 2002 DPA decision, it stated: “Radio may be designed around the use of music and musical genres but as a cost, and (probably) as a drawing card, on-air talent is far more important” (Copyright Board of Canada 2002, p. 8). If so, one may estimate that on-air talent generates far more and music far less than 50% of revenues, that is, say 60% and 40%.

As such, the resulting percentage rate of music royalties expressed on the basis of music-generated revenue would be 21.0 (= 8.4/0.4)%. Increasing that percentage rate by 25% to account for the larger use of music in DPA would yield an equivalent rate for DPA, i.e., 26.3%.

Hence, the percentages, which would satisfy both the principles of technological neutrality and balance, assuming that the commercial radio rates are properly set at their competitive market value level, would be, 8.4% of revenues for Commercial Radio and 26.3% of revenues for Digital Pay Audio services, before any adjustments for repertoire or other reasons.

Naïve Consumers: Contract Economics

Elena D'Agostino
Department of Economics, University of
Messina, Messina, Italy

Abstract

Consumers are viewed as a weak contract party by both lawyers and economists, although with some distinctions. The unconscionability theory addresses consumers' naïvety, to be intended as partial or total incapacity of understanding contract terms, as a reason for public intervention. Economists as well agree that law must protect consumers against sellers' abuses, especially when contracts contain add-ons or are preprinted and no bargaining is allowed.

How law should intervene is still an open question. On the one hand, lawyers point out that courts should not enforce contract clauses literally but rather should replace them with terms that consumers could have reasonably expected and approved. On the other hand, economists focus on how sellers exploit naïve consumers and warn that regulation may turn out pejorative if it is not able to educate naïve consumers or if it allows the seller to raise the price up when forced to offer good terms.

The Notion of Naïvety in Law

Consumers can be viewed as a special category of buyers that has magnetized lawyers and economists' attention in the last decades. A distinction is, however, necessary to highlight what the two disciplines have in common and nevertheless why they differ.

Starting from a legal point of view, when lawyers refer to consumers, they have in mind a weak and nonprofessional contract party with limited or no contract power, and usually uninformed of every clause or consequence of the contract signed (see Korobkin 2003). This sort of considerations has driven the legal literature to formalize a general theory of unconscionability: accordingly, it is unconscionable a contract that mentally competent people would not sign and/or that no fair and honest person would accept. Not surprisingly, consumers' naïvety, to be intended as partial or total incapacity of understanding the contract content in each of its clauses, has been viewed as one of the main factors to support the theory of unconscionability.

Accordingly, since consumers may sign the contract without reading or understanding its content, their signature on the contract may not correspond to a meaningful consent to all its clauses. It comes out that courts should not enforce contract clauses literally, especially those so one sided

to turn out vexatious, but rather should replace them with terms that consumers could have reasonably expected and approved.

The Notion of Naïvety in Economics

On the other hand, economists make a second-order distinction between two categories of uninformed consumers: those who are simply uninformed but conscious of the potential risks hidden into a contract that has been prewritten by the counterparty and those who are not only uninformed but also unconscious of such risks. Consumers in the former category are labeled “rational” or “sophisticated” and are usually assumed to be able to fill their knowledge gap by paying a positive cost to read contract terms. Consumers in the latter category are labeled “boundedly rational” or “naïve” and are assumed to never read the contract simply because they do not realize the risk of signing without reading.

Ellison and Ellison (2009) analyze how firms can exploit consumers’ in Internet transactions where price search engines make a price search more difficult and sometimes not convenient.

As pointed out by Armstrong and Chen (2009), it does not imply that naïve consumers do not care of contract clauses at all or less than sophisticated consumers. There might be also consumers who are naïvely pessimistic, that is, they do not trust the seller and believe that contracts always include unfriendly clauses. More generally, we can say that naïve consumers simply do not realize the risk involved in signing a contract without reading or they never trust the seller and never sign.

Similarly to the legal literature, there is a general consensus in the economic literature as well that court intervention is necessary to protect naïve consumers. To be more precise, economists have focused on how unregulated seller(s) exploit such consumers. The answer clearly depends on the beliefs that naïve consumers hold about the terms in preprinted contracts. Despite in some

contexts a consumer might expect complex contracts to contain default terms (e.g., he might believe that the non-price terms in a complex contract address contingencies which are irrelevant to the buyer and are therefore regulated by default rules or uses), most of the literature prefers focusing on the case in which consumers are weaker and easier to exploit for a contract-drafting seller: it happens when consumers are naïvely optimistic, believing that preprinted contracts contain favorable terms.

The Effects of Regulation

A recent behavioral literature treats the infrequency of reading as indicative of buyer naïvety and argues that sellers lack an incentive to educate such buyers: cf. Gabaix and Laibson (2006) for the special case of add-on goods and D’Agostino and Seidmann (2016) in respect of contracts of adhesion. The intuition is the following: if all buyers believe that complex contracts contain favorable terms, then an unregulated seller would include the worst possible terms in preprinted contracts charging the price that buyers would be happy to pay for friendly terms according to those constraints imposed by the market structure in which they operate. Regulations may therefore benefit such naïve buyers.

Despite the general principle that parties are free to negotiate contracts, courts, legislatures, and regulators have sometimes overruled onerous terms in consumer contracts. There are two underlying and potentially conflicting rationales: Sect. 218 of the Uniform Commercial Code states that a clause is unenforceable if a buyer would not have traded had he known its contents, which suggests that naïve buyers should be protected. By contrast some courts, notably in *Henningsen v. Bloomfield Motors* (NJ 1960), have cited market share as an aggravating factor, which suggests that all buyers should be protected against sellers who exploit market power to offer onerous contracts.

It is also unclear whether regulations are designed to protect buyers who have already accepted onerous terms (and must necessarily gain) or to protect buyers who have yet to enter the market.

Suppose all consumers are, economically speaking, naïve in the sense that they believe that contract terms are favorable and do not take into account the risk of accepting a preprinted contract without reading its content. Sellers in a free market would therefore include onerous terms in their contracts charging the highest price that such consumers are willing to pay for favorable terms. Consumers therefore risk to get a negative payoff, to be intended as the difference between their evaluation for an onerous contract and the price they pay believing that it is rather favorable, under the supposition that they value more a favorable contract than an onerous contract.

Trivially, regulations which do not educate buyers have no effect on play: if naïve consumers remain unaware of the effect of regulation, they will not be able to call the seller in front of a court of law if terms are different from those legally acceptable. Conversely, effective regulations which either mandate terms turning out favorable to consumers or prohibit rather onerous terms induce both a monopolist and each competitive seller to offer a favorable contract, but the effect on price crucially depends on the market structure. Precisely, a monopolist will charge the highest price that consumers are willing to pay for those terms, whereas competition will lead price down to the production cost. As an effect, consumers get zero from buying and may be better off compared to a free market in which they would have been offered onerous contracts charging a price close or equal to their reservation price for a favorable contract.

Suppose now that some consumers are naïve and some others are rational. If rational consumers must pay a cost to read and understand the contract, a commitment problem arises and an unregulated seller has again no incentive to include favorable terms. Precisely, consumers cannot commit to read the contract and seller (s) cannot commit to include favorable terms. As

a consequence, an unregulated seller cannot charge a price equal to consumers' reservation price for favorable terms if he plans to trade with rationals, but under some conditions he may find it profitable to include favorable terms with positive probability if rational consumers read with positive probability. Naïve consumers are therefore protected by rational consumers if the latter category is sufficiently large in the market to force seller(s) to reduce the price and possibly to include favorable terms with positive probability. Conversely, if naïves represent a large percentage of consumers into the market, then seller(s) will ignore rationals and equilibrium conditions correspond to those found when all consumers are naïve. Focusing on the former and more interesting case, regulation will force sellers to offer favorable terms with market structure dictating the equilibrium price. The effect on naïve consumers' payoffs is therefore ambiguous depending on what price they were charged in a free market given the probability of finding favorable terms.

National Locus

Giuseppe Eusepi

Department of Law and Economics of Productive Activities, Sapienza University of Rome, Faculty of Economics, Rome, Italy

Abstract

The idea of nation grew out of the ancient idea of law and subsequently evolved in the form of national states as territorial boundaries. The unitary national state turned what was an internal conflict between a statesman and a merchant into an external conflict among nation states. As the USA and the EU demonstrates, the concept of nation state as a public good is either ambiguous or tautological. In a more or less distant future, the national locus is apt to move from a territorial to a procedural dimension.

Synonyms

[National identity](#); [National law](#); [Nation-state](#)

Definition

National consciousness as opposed to nationalism.

The idea of nation has been worked out by the Romantic movement, and it may be regarded as the force that set in motion movements engaged in asserting national identities in Europe such as the Italian Risorgimento (Salomone 1970) and the German Nationsbildung (Hroch 2005), which began during the first half of the nineteenth century and extended until the second half of the century and beyond.

The progenitors of the idea of nation are to be found in the idea of state, which marks the end of the Middle Ages and the beginning of the Modern Age, and much earlier in the idea of law that had its roots in ancient Greece and, above all, in ancient Rome. In ancient Rome, law was basically

a private law: the ideas of law and order guaranteed private property and the related freedom of exchange.

Nineteenth-century idea of nation capsizes the private-public law relationship, which shaped the ancient Roman law. The conflict between public law and private law is best represented by the perennial conflict between a statesman and a merchant: the former operates for the purpose of bringing about adjustments of relations among individuals, and the latter is concerned with individuals' desire to get rich. The idea of nation emerged exactly to nuance this conflict by turning conflicts within the nation into conflicts outside the nation. The concept of national locus separates the nation as a unit from the rest of the world. In symbolic terms, the national anthem and the flag symbolize the national locus by definition, but from a more rational point of view, the clearest definition of national locus is the Constitutional Charter and constitutional political economy *sensu lato* (Buchanan and Tullock 1962). The clue to constitutional political economy is to be found in the consensual-contractual dimension, which is the outward form of the inward notion of metarule; thus, the notion of national locus becomes constitutional locus. In this context, the centrality of the constitutional law requires that control on application of the law be operated by a judge acting objectively and impartially just as a judge of the Constitutional Court.

Standard or mainstream economic thinking has been much concerned with a substitute for the procedural component, which was viewed as irrelevant. One such substitute has been seen in the objective dimension with the consequence that the concept of national locus loses its process connotation (including the democratic one) and becomes a measure of an optimal national quantity commonly lumped in the label GDP or better public goods. In its widest abstract sense, the concept of national locus can be pictured as a defense or protection line against external invasions by other nations as well as by foreign goods. Although the concept of national locus seems to have strengthened itself in public economics, especially in the form of Samuelsonian national public goods, nevertheless it is not free from

conflicts. And, in fact, the conflict arises, not only because the distinction between national public goods and local public goods is not so sharp but because the theoretical foundations of the national and local dimensions may be ambiguous. National public goods, if we are to understand what they really are, should be viewed in their territorial dimension – and in this case the distinction is tangible but tautological. There is in fact a difficulty in drawing a line between “local locus” and “national locus” because they shade into one another and give rise to a dimensionally ambiguous concept, which is not clearly determined. The same may be said of the national locus vis-à-vis the supranational locus. The United States and the EU are a flagrant example of this indeterminacy. While in the United States the federal government is the emblem of the national community (national locus/national constitution), in the EU, member states (national loci) are a subset of a supranational body.

Despite its manifest negativity, this ambiguity is tonic to the advancement of the very idea of national locus. No doubt it is too soon to foreshadow an era in which the concept of national locus is conceived of as separated from the concept of nation as territory. But there seems to be good ground for asserting that the national locus will increasingly move over from a spatial dimension to a procedural dimension (supranational alliances). Moving from a territorial dimension to a procedural dimension involves the abandonment of the concept of nation and a stricter role for law and rules.

In a nutshell, the national locus is a notion moving a great distance away from a territorial symbolic connotation of a nation clustering around its hymn and flag. Against this background, the national locus is apt to transform itself into the notional locus of the law (Eusepi 2008) built up over the two foundations of the law: civil law and common law (Pound 2000).

Negotiated Procedures in EU Competition Law

Frédéric Marty¹ and Mehdi Mezaguer²

²CNRS – GREDEG, Université Côte d’Azur, Université Nice Sophia Antipolis, Valbonne, France

Definition

The enforcement of EU competition law in the field of antitrust, e.g., the sanction of abuse of dominant position and collusive agreements, increasingly uses negotiated procedures. Negotiating remedies with incriminated undertakings is a well-known practice in the field of merger control. The practice of settlements is also significantly developed in the United States. However, it remains a relative new approach under the EU competition law enforcement. This chapter presents the three main tools at the disposal of the EU Commission: the leniency program, the direct settlement, and the commitment procedures. It

analyses their main challenges and issues in both legal and economic fields.

Negotiated Procedures Under EU Competition Law: An Introduction

Negotiated procedures under EU competition law mainly encompass three procedures: leniency, commitments, and direct settlements. We mainly consider the negotiated procedures implemented for the application of Articles 101 and 102 of the Treaty on the functioning of the European Union. We draw some parallels with remedies in merger and acquisition control.

These procedures are provided under European Union law using a specific framework. Firstly, they were organized around both soft law and hard law after a period of insecure practice on the shadow of law: Sunlight is said to be the best of disinfectants and the twilight zone in which settlements currently are negotiated, desperately needs light (Van Bael 1986). Secondly, these procedures stemmed from the practice of the European Commission. The Commission increasingly tries to organize its intervention on the market using cooperation with companies for the application of EU competition law (in our case, it is mainly antitrust law). Thirdly, these procedures are organized under the notion of mutual concessions which allows an approach based on rationality. Between main legal instruments and the peripheral ones, a particular dynamic has been installed to the advantage of the public authority. Under EU law, the European Commission is clearly at the center of the proceedings. From that perspective, negotiated procedures have to be discussed above all around the question of their essential nature: Do these procedures pertain to a logic of cooperation with the public agency or to a real negotiation between two partners?

Understanding the reality of these procedures implies to put into light the interests for companies and the public authority, appreciate both legal and economic approach, and consider the problems of the procedures under fundamental rights.

An Overview of EU Negotiated Procedures for Articles 101 and 102 TFEU

The Negotiated Procedures Before the Negotiated Procedures

Understanding the specificities of EU competition law-related negotiated procedures supposes to consider the historical dynamic that led to them, especially the experience of the ad hoc agreements that were implemented in the field anticompetitive practices before the EU 1/2003 Regulation, and to make some connections with the case of remedies in merger controls.

The informal practice of the negotiated practices is a specific situation under EU competition law. Indeed, the European Commission has started in the 1960s to relay on informal arrangements following the fundamental principle that no situation is ever lawful or unlawful forever (see, e.g., cases *Nicholas frères* (Commission Decision 64/502/CEE, 30 July 1964) and *Henkel-Colgate* (Commission Decision 72/41/CEE, 23 December 1971). The European Commission was at this time in charge of a very innovative field, and this type of *cooperation* could have been seen as a will to implement softly antitrust law. The first decisions applying such an approach were mentioned in the reports on competition law by the European Commission and have mainly concerned agreement cases (abuses of domination cases appeared in the beginning of the 1980s). For example, in its first report in 1971, the Commission explained such situation by the need of saving resources. In its fifth report, issued in 1975, the Commission mentioned the “friendly” nature of its intervention. Anyway, in that period, the informal intervention of the European Commission was not well known by public or academics, and the Commission itself was not really able to explain the nature of such procedures (when questioned, e.g., by a resolution of the European Parliament in 1987).

As a consequence, the informal development of negotiated procedures has created some uncertainties, particularly since it was not possible to isolate each procedure according to its specificities. From this perspective, the creation of a formal architecture allowed an individual and global

understanding of negotiated procedures. The formal scheme also had to respond to the need for legal certainty and clarification regarding practices involving cooperation through reciprocal concessions. The resulting procedures, without claiming similarity, converge on several points but need at the same time to be presented over their singularity.

When working on the proposal of a new framework for the application of Articles 101 and 102 (former 81 and 82), the Commission provided that: “The second way in which the proposal will increase the protection of competition is by allowing the Commission to concentrate on the detection of the most serious infringements” (EU Commission 2000). Negotiated procedures aimed indeed to increase efficiency in law application by the liberation of available resources. This has to be considered as a real philosophy at the European level which led to the creation of a formal framework of three procedures qualified as negotiated (Mezaguer 2015).

Leniency Procedures

The first procedure corresponds to leniency programs. These procedures were created only under soft law. Indeed, in 1996, 2002, and 2006, the European Commission has adopted three communications for the organization of the proceedings. The first communication provided that these procedures were intended to apply competition rules with efficiency. The 1996 communication on leniency introduced the first formal instrument providing a legal framework for negotiated procedures under EU competition law. Nevertheless, in the first times of the regulation 1/2003, which constitutes the main instrument of EU antitrust law, no mention of leniency procedures was made. Finally, Regulation 2015/1348 has mentioned such procedures but only related to Regulation 773/2004 which provides only procedural rules. The legal situation of leniency is rather paradoxical.

However, leniency has become a major instrument of cartel resolution even in member states of the EU. Moreover, the European model is a reference for member states even if, in a 20 January 2016, *DHL Express*, C-428/14 case, the European Court of Justice has provided that the creation of

leniency program was not an obligation for member states.

Leniency gives several ways of cooperation to the competition authority and to the incriminated undertakings from different perspectives. Firstly, the company denouncing the cartel runs for immunity if it shows a “true spirit of cooperation.” This situation was generalized under the 2002 communication and differs from the US situation while even the first company is recognized guilty (but without any fine). The condemnation of the first company to a zero euro fine will probably have a specific importance for follow-on civil actions (even if the present framework is questionable, see, for instance, Cauffman (2011) and Mezaguer (2015)). Nevertheless, the first company to denounce must obtain a reward far superior to those who follow it so that the leniency program can be efficient. A leniency program should initiate a denunciation race among the cartelists to be efficient.

After this first company, leniency will allow other cartelists to receive rewards (between 5 and 50% depending on the period) for not disputing the facts, for giving valuable material for the proof, and for going through useful cooperation with the Commission. From this perspective, cooperation implies express, clear, and precise recognition of the facts (*Tokai Carbon*, Court of First Instance, 29 April 2004, joint cases T-236, 239, 244, 246, 251, and 252/01). Lower-rank leniency maintains incentives for the companies to engage a race for cooperation. From this perspective, companies are no longer supposed to help in the mere initiation of the investigation, as it is the case for the first-rank leniency, but must reinforce the Commission in its work of qualifying the infringement. Indeed, it is well known that “a reduction in the fine will be granted for a contribution during the administrative procedure only if that contribution enabled the Commission to establish an infringement with less difficulty and, where appropriate, to put an end to that infringement” (Conclusions of the Advocate General Geelhoed, *Commission v SGL Carbon*, 19 January 2006, case C-301/04 P). Finally, the Commission benefits from a wide margin of interpretation to reward companies. This range of

reductions distinguishes the leniency from the direct settlement procedure.

Direct Settlement Procedures

The transaction procedure corresponds to direct settlements. This procedure has been created through both a Communication of 2 July 2008 (2008/C-167/01) and a Regulation of 30 June 2008 (n° 622/2008) of the European Commission. This Regulation has modified the specific procedural regulation 773/2004, which entirely relies on the European Commission, and not the general one. Even if the use of regulations contrasts with the soft law, the European Commission is still at the center of decisional power. Moreover, the direct settlement procedure is also seen as a piece of a general transactional scheme for cartel resolution with the leniency program. Under the direct settlement procedure, companies who plead guilty before the Commission can expect a 10% fine reduction. At the creation of the procedure, former competition commissioner Neelie Kroes (2005) suggested that “we may need to look at how some form of plea bargaining procedure could bring advantages.” Under the actual framework for direct settlement, companies that “plead guilty” and take a commitment not to contest the conclusions of the Commission receive a 10% reduction of the fine as a reward (the reward is combinable with leniency ones). Consequently, direct settlement is a hybrid procedure between American “plea-bargaining” and French-style “non-contestation des griefs.” It is more a simplified procedure than a negotiated one.

Commitment Procedures

Commitment procedures were the first ones which were included in the general Regulation 1/2003 since their creation (Article 9). Commitment procedure has to be distinguished from leniency and direct settlement first of all because it does not apply to cartels. Indeed, Regulation 1/2003 clearly provides that such a procedure is not possible when the Commission intend to impose a fine. As for other “negotiated” procedures, commitment procedure relies on an efficiency-based objective. Concerning the question of its application under Article 101 or 102 of the TFEU, The

Alrosa/De Beers case (Court of Justice, *Commission v Alrosa*, case C-441/07, 29 June 2010) has shown that Article 9 could be used in both situations (Mezaguer 2015).

Under the commitment procedure, things are clearer. Indeed, when the Commission intends to adopt a decision (requiring that an infringement be brought to an end), the companies can offer commitments meeting the concerns of the public authority, which are expressed in a preliminary assessment. From that perspective, the Commission adopts a decision making those commitments binding on the companies. Moreover, Article 9 of Regulation 1/2003 provides that “Such a decision may be adopted for a specified period and shall conclude that there are no longer grounds for action by the Commission.” Before issuing a decision making the commitments bidding the Commission must submit them to a market test procedure to invite all the interested parties to make comments. These ones aim at helping the Commission to discuss these initial proposals and to require if necessary the proposal of modified ones.

What Are the Reasons to Commit into These Procedures?

We analyze the determinants of the choice to opt for a negotiated procedure by taking successively the point of view of the competition authority and the one of the undertakings.

The Theoretical Advantages of Negotiated Procedures for a Competition Agency

We first present the common advantages of all the negotiated procedures in competition laws for an enforcement agency before considering specifically some advantages related to leniency programs and to commitment procedures (Wils 2008).

Firstly, negotiated procedures aim at reducing administrative costs for the enforcement agency. Indeed, the negotiated option may lead to a shorter duration and to reduce the burden of proof. Secondly, a negotiated settlement allows the competition authority to obtain more rapidly the end of the prejudicial practice. Such a result is also

obtained possibly more surely, as the firm chooses and implements itself the remedy that it had proposed on a voluntary basis. Thirdly, the negotiated procedure in itself limits the information asymmetries between the undertaking and the authority. The last one has not demonstrated the existence of an abuse or of an agreement and has not assessed its effects. In addition, for the commitment procedures, the uncertainties related to the adequacy and to the proportionality of the remedies proposed by the undertaking are limited through the market test procedure, which allows the authority to benefit from the opinions of the different stakeholders (consumers, competitors, etc.). Fourthly, it limits the risk induced by an adversarial procedure. To the extent that the competition authority has neither to assess the net effect of the market practice at stake on the consumer welfare nor to consider the defense of the incriminated undertaking, it reduces at the minimum the risk of being disavowed by the appeal court. Fifthly, negotiated procedures, especially the commitment ones, lead to implementation of compliance programs and by doing so favor the dissemination of a competition culture within the organization. Sixthly, the guarantees about the effectiveness of the remedies are enhanced by the fact that a failure in their implementation would lead to an automatic fine, irrespective of any assessment of the effect of this nonfulfillment. For instance, Microsoft was fined on this basis for its negligence in its implementation of the remedies negotiated in the MS Explorer case, as we will see below.

In a more specific way, we can consider that negotiated procedures have two main types of advantages for competition authorities. It avoids the burden of the characterization of competition law provisions infringement through material or economic evidences. For instance, in the case of leniency programs, the material evidences are brought by the undertaking applying for leniency. The second main advantages consist in the effect of the decision on market structure or on the dominant undertakings' future behavior. A fine mainly produces a deterrence effect. It does not lead to correct the effects of the previous market

practices. In a very opportunistic spirit, the fine can be seen by a dominant firm or by the cartelists as the *cost of doing business*. On the contrary, a negotiated decision leads to behavioral or even structural measures that may remedy to an unsatisfactory situation on markets and to some extent to reestablish a level playing field on the market. It may ensure for the future a fairer and more effective competition.

An adversarial decision, as the *Google Shopping* one (June 2017) or the *Android* one (July 2018), for instance, might lead to equivalent corrective measures through the injunctions to provide an equal treatment to rival comparison shopping services and its own services in the first case or to end its tying practices and to allow the development of *fork Android* operating systems, in the second case. However it remains that these two Commission decisions are both appealed before the General Court. Even if, the General Court and the Court of Justice will uphold these injunctions, their implementation will must be strictly monitored. Such remedies will be challenged and at best implemented in a noncooperative way. At the opposite, a commitment procedure participates to a jointly constructed competition regulatory approach and not only to an ex post legal enforcement of competition law provisions. It remains that the negotiation at stake is not really a horizontal bargaining between two equal partners but rather a transactional agreement with a public authority within a vertical relationship. The EU Commission *Google Shopping* case demonstrated that the two "partners" were not in equivalent position.

The Advantages Considered on the Incriminated Firms' Side

For the incriminated undertaking, opting for a negotiated procedure may reduce significantly the procedure duration. Indeed, the shorter the case, the less expensive its costs in terms of financial resources, management attention, and reputational effect (especially on the stock market). In addition, avoiding any recognition of guilt may induce two main benefits: Firstly, it makes successful follow-on actions for damages less probable, and, secondly, it allows to stay away from any

fine increase in a future case grounded of the aggravating circumstance of repeated offense.

In the specific case of leniency programs, the undertaking applying for the leniency may hope exiting from a cartel agreement without any legal (defense) costs or administrative sanction, as fines. In the case of a direct settlement, the undertaking benefits from a fine reduction. In other words, the fine may be reduced outside the scope of leniency since the undertaking does not challenge the theory of damage presented by the competition agency or its assessment of effects. In addition, the commitment procedure allows the undertaking to avoid to be fined and to have to recognize to have breach the law. In addition, the undertaking still benefit from informational asymmetries allowing to propose the less costly remedies possible.

Considering all these advantages on both sides, negotiated procedures seem to pertain to a *win-win strategy* (Bellis 2013).

The US Origins of Negotiated Procedures in Competition Law: What Can We Learn for EU Ones?

The Antitrust Division head, Thurman Arnold, has played an essential role in this resolved use of these settlements rather than opting for adversarial procedures before courts (Waller 2004). In the competition law-related field, the negotiated procedures constitute a US transplant. It is worthwhile to consider the US antitrust history to put into relief the main features and the underlying logic of these procedures. Although the real start of the large implementation of settlement procedures by the Antitrust Division of the Department of Justice (DoJ) can be dated in the late 1930s and in the late 1940s, the first Antitrust Division's consent decrees was the *US v Otis Elevator Company* in 1906.

How to explain this specific choice at this moment of American antitrust history? The F.D. Roosevelt administration was disappointed about the results of the cooperation with dominant firms during the *National Industrial Recovery Act* (NIRA) implementation before its invalidation by the Supreme Court. Big firms were suspected of

having not fairly play the game of an economic coordination based on government support to promote investment and employment. The coordination among firms effectively led to stop price drops, but it mainly allowed firms to increase their markups without effective counterparts. This disappointment has pleaded for a public antitrust enforcement renewal, especially because, the government benefited from a large portfolio of easy-to-win cases. The NIRA agreements supervision had led government agencies to accumulate data and evidence about collusive practices. The government position was also comforted by the TNEC report conclusions. The Temporary National Economic Committee established in 1938 aimed at analyzing the monopoly powers in the US economy. While government accumulated evidence about collusions and monopolization practices, why did Th. Arnold opted for settlements and not for conventional antitrust procedures? The reasons were twofold. The first one was to obtain quickly effective results by avoiding endless legal procedures. The second one was also related to a procedural concern: averting the legal risk induced by a still conservative Supreme Court case law.

This historical experience is all the more relevant for us that the EU Commission itself has used these kinds of procedure after sector-specific enquiries in order to avoid General Court and Court of Justice legal control and to circumvent member states' reluctances to accept legal proposal aiming at liberalizing some economic sectors as utilities. We may provide the example of the energy sector enquiry in 2005–2007. A large number of formal procedures were opened after this enquiry against gas and electricity dominant operators across the EU (Hancher and de Hauteclocque 2011). For all except one, the final decision was not an infringement one but a negotiated one. Even nowadays, far-reaching and broad scope competition law remedies are obtained through commitment procedures in the EU energy sector as testified in the May 2018 *Gazprom* decision (case 39.816 Upstream gas supplies in Central and Eastern Europe, 24 May 2018).

However, US and EU procedures and practices remain specific. In the US case, for instance, for

the Antitrust Division of the DoJ, an antitrust settlement is a horizontal contract between the firm and the agency that requires judicial supervision. Indeed, the 1974 Tunney Act requires an *ex ante* judicial review of the DoJ consent decrees. Whatever the supervision of these agreements, it remains that the US antitrust enforcement realized a shift from a litigation-oriented model toward a more regulatory-based regime. The balance between courts and agencies has shifted dramatically toward the last ones. Ginsburg and Wright (2012) showed that by the 1980s, already 97% of the DoJ antitrust cases were settled. From 2004 to nowadays, almost all its cases were resolved through these negotiated procedures. The tendency is the same considered on the FTC side.

In cartel-related cases, the rise of negotiated procedures was later but equally important. The US corporate leniency program was first introduced in 1978. It was revised in 1993 and completed by an individual leniency program 1 year later. Its scope of application covers agreements aiming at setting prices, market or consumer sharing devices, and bid-rigging practices. From the initial 1978 procedure to the 1993, three major revisions were implemented: (1) leniency is now automatic for qualifying companies if there is no preexisting investigation; (2) leniency is still available even if cooperation begins after the investigation is underway; and (3) all employees who come forward with their company and cooperate are individually protected from criminal prosecution. The real start of the US leniency program can be dated 1993: from 1993 to 2010, US enforcement data reveal a 20-fold increase. Nowadays, in the USA 90% of the penalties imposed by the DoJ were linked to leniency-related cases (OECD 2018).

The institutional specificities of the US enforcement regime may explain this precocious and fast development. Opting for a negotiated procedure might be a rational choice for an enforcement authority while considering the judicial and political risks associated to unfruitful lawsuits. In addition, the burden of the rule of reason had grown earlier in the USA as the shift toward an effects-based approach in antitrust laws enforcement started at the late 1970s. This

tendency also raises a theoretical question: are the settlements more efficient in terms of administrative performance (deciding cases quicker and easier) or in terms of obtaining concessions from the firms for *not-so-easy* cases for which the enforcement agency has no certainty about its own chances to be successful before a court? Such a game relies on the fact that the competition authority does not disclose its evidence and remains vague on the theory of damage or on the assessment of the damage to competition. As we have already mentioned for the EU competition law case, the enforcement agency does not issue a statement of objections but only a communication of competition concerns. The second player – the incriminated firm – does not know what the competition agency exactly knows and what its real chance of being convicted are. Because of the asymmetry of information that benefits to the authority, a risk-averse undertaking may prefer enter in a commitment procedure. Indeed, the trade-off between prohibition and commitment decisions cannot be analyzed without taking into account uncertainties related dimensions (Gautier and Petit 2018).

Is the tendency observed for the EU competition law enforcement as significant as it is for the US Case? From 2007 to 2017, we count 19 Article 7-based decisions (antitrust prohibitions) and 32 Article 9-based ones (antitrust commitments). If we consider the case of cartels, we may count 40 cartel prohibition decisions (based on an adversarial procedure) and 25 based on settlements. However considering on the period from 2013 to 2017, the balance is rather different with 7 adversarial procedures and 18 negotiated ones (EU Commission 2018). The same constraints tend to produce the same results. In addition, we have to keep in mind that competition law enforcers are engaged in convergence process.

Economic and Legal Concerns Related to the Recourse to These Procedures

This conclusion illustrates some of the economic and legal issues raised by the recourse to negotiated procedures. We first consider the case of

leniency programs before considering the one of commitments. We finally consider the nature of these procedures in order to draw a dividing line between negotiated ones and transactional ones.

A Law- and Economic-Based Discussion of the Possible issues Raised by Leniency Programs and Commitment Procedures

The case of leniency programs raises several issues within the economic field. For instance, what about the incentives to collude while the expected cost of the sanction is reduced while a firm anticipates that she will be the first to betray its partners in crime? Do these procedures only lead to dismantling only poorly efficient cartels? Should it be necessary to grant a monetary reward to the cartel member who reports a cartel agreement before any investigation (Brisset and Thomas 2004)? Considered at the legal point of view, how to consider the capacity of a cartel, possibly the initiator of the cartel, to escape at any sanction after a breaching of competition laws? How to articulate public and private enforcement, especially if we consider the follow-on actions aiming at obtaining damages? The near predominant part of leniency procedures in the cartel-related competition law enforcement undoubtedly raises issues in terms of restorative justice. At the same time, controversies over differences in the treatment of unilateral practices in the USA and the European Union can be read through the prism of relative weight differences between public and private enforcement (Cosnita-Langlais and Tropeano 2018). The rise of leniency programs in the US case and its consequences in terms of private enforcement do not raise the same issues as in the EU where follow-on actions have to be encouraged (see, for instance, Bueren and Smuda 2018).

The development of commitment procedures also leads to raise several issues in the economic field. For instance, how taking into account information asymmetries to assess the adequate, effective, and proportionate character of remedies? It raises significant adverse selection-related concerns. Do the behavioral or structural remedies proposed sufficient to address competitive concerns? For instance, in case of asset divestitures,

are the values of these last ones properly selected? Will the future buyers able to exert an effective competitive pressure? The EU procedure of the *up-front buyer* aims at limiting the risk to transfer the asset to a market player who has not the financial or technical capacities to compete or has excessive incentives to collude or to avoid a too fierce competition with to dominant firm. For instance, a divestiture benefiting to a major competitor may create a symmetry among the main competitors within the relevant market and by doing so enhance the risk of collective dominance.

These concerns are not the only one induced by the information asymmetries at stake in commitment procedures. The supervision of the proper implementation of remedies also raises moral hazard-related issues. Will the undertaking implement properly and efficiently the remedies it has proposed? According to EU regulations, a failure to comply with commitments that a Commission's decision made binding leads to an automatic sanction. Microsoft experienced the situation with its €561 million fine imposed to its failure to provide European users a screen choice of web browsers from May 2011 to July 2012 despite its 2009 commitments (see the EU Commission decision, case AT.39530, *Microsoft*, 06/03/2013).

Symmetrically, information imperfections may lead the antitrust enforcement authority to require excessive remedies. Farrell (2003) illustrated this case for mergers remedies with the scalp, overfixing, and broad scope phenomena. The first one corresponds to an application of disproportionate remedy from a dominant firm in order to sanction its past behaviors or to address its structural dominance. The second one consists in requiring remedies going beyond what is necessary by taking into account the information asymmetries that the undertaking does benefit. It plays the role of a security margin. The third phenomenon corresponds to remedies unfitted to the damage theory presented in the communication of the competition concerns. It might correspond to a situation in which the competition authority takes advantage of the negotiated procedure to address several issues even if all of these ones are not closely related to the case.

Such phenomena may be difficult to observe in adversarial procedures mainly because of the judicial control exerted on them. However, this control is by far relaxed under the EU competition law by the Court of Justice judgment in *Alrosa* (EU Court of Justice 2010). To the extent that the remedies are voluntarily proposed by the undertaking, the EU Commission has not to check if less demanding or less intrusive remedies might be proposed. If the EU Commission has also to perform a proportionality test, this last one is limited to the remedies effectively proposed by the undertaking. In other words, if the dominant undertaking only proposes structural remedies, the authority has not to verify if behavioral ones may allow to obtain similar effects. These specificities may lead to concerns about competition authorities' capacity to obtain "excessive" remedies in these negotiated procedures. It may be illustrated, for instance, by the case of divestitures. These last ones are seldom used in adversarial decisions (Article 7) but can be observed in Article 9 ones. The case of the European energy sector is emblematic of such difference. The EU case may be all the more specific that the incumbent has special duties regarding the effectiveness of competition. This duty may increase the probability of being fined under a conventional procedure. It enhances the incentives to opt for negotiated procedures, and it simultaneously increases the potential cost of a negotiation failure if the Commission will decide to go back to a conventional procedure. The Google case is striking example of such a risk. Taking into account this one may induce some bias in the "negotiations" by leading firms to propose "disproportionate" remedies in order to have a greater probability to see these ones accepted.

Indeed, the use of negotiated procedures raises issues in terms of remedies proportionality. If we insist on the importance of information asymmetries, we may fear that a dominant and better-informed dominant undertaking may propose insufficient remedies or may behave strategically during their implementation in order to reduce their effect. In the same way, we might take into consideration the risk that the competition agency tends to opt for settlements while its

expectations to win before courts are unfavorable. The risk in such a case is to negotiate unsatisfactory remedies to close the procedure. However, as we have underlined, the symmetrical risk cannot be minimized, especially if the dominant undertaking does prefer avoiding a prohibition decision, taking into account its reputational impacts, its induced risks in terms of follow-on actions, and possibly the possible fine increases in future decisions on the basis of the aggravating circumstances pronounced in case of recidivism.

This competition authority's strong position in the bargaining may lead to costly remedies for the incriminated dominant undertaking. We can provide an example in the domain of mergers with the *Bayer/Monsanto* case (decision of the European Commission; 11 April 2018, case M8084). Bayer took the commitment to sell to BASF a part of its activities in order to prevent a possibly non contestable position in the market of seed and pesticides. The Commission has required an up-front buyer condition. It led to limit the number of potential acquiring firm and possibly to reduce the transfer price. The up-front buyer requirement aims preventing to transfer the assets to a non-efficient market operator who cannot exert a long-term credible competitive threat on the dominant firm. Such a requirement makes sense in order to protect the competitive process, while it has an adverse effect on the dominant firm's interests.

At the legal point of view, commitments procedures may also raise several concerns. Firstly, what is the proper scope of competition law remedies? Should these ones concern prices? On the principle, it has not to. The competition authority has not the play the role of a price regulator. Nevertheless, as soon as an essential facility is at stake, commitments deal with access price-related issues. Compulsory licensing-based remedies also raise the same concern. An even more far-reaching question could be put into relief for remedies aiming at reinforcing the competitive situation of a given market.

Again, the *Gazprom* case can be relevant to illustrate this situation. In 2015, the Commission sent to Gazprom a statement of objections. According to the Commission's preliminary view, this company breached EU competition

rules by pursuing an overall strategy to partition gas markets along national borders in several member states in Central and Eastern Europe. This strategy may also have enabled Gazprom to charge higher gas prices. The remedies proposed by Gazprom and negotiated with the EU Commission both address these competitive concerns and deepen the gas internal market. They do not sanction an anticompetitive behavior by pronouncing a fine in a deterrence purpose as a prohibition decision would do. These remedies pertain to the building of competitive markets. The competition field will be not the same before and after the remedies. It is not an issue to reestablish the condition of a free and undistorted competition but an issue to create a competitive market.

What are the remedies in this specific case? A first one undoubtedly pertains to a logic of guaranteeing the end of the alleged anticompetitive practices. Gazprom commits to remove all the contractual provisions that imposed geographical restrictions or that limit the customer's capacity to resell Russian gas. A second remedy concerns gas prices. A structured process to ensure competitive gas price will be put in place in order to guarantee that Russian gas price will be aligned with the prices observed on Western European market places. The third remedy may contribute to change the competitive structure of the gas market itself: "Gazprom will enable gas flows to and from parts of Central and Eastern Europe that are still isolated from other Member States due to the lack of interconnectors, namely the Baltic States and Bulgaria." In other words, this commitment will oblige Gazprom to open its network for intra-EU gas exchanges. This remedy is a quasi-structural one. It will play as an alternative to new investment in new gas infrastructures within the EU.

A Legal Perspective on the Commitment Procedure

The rise of commitment procedures may raise other concerns in the legal field. Firstly, the negotiated procedures under the EU competition regulations lead to limit the scope of judicial control. It may question the effectiveness of the guarantees that protect the fundamental rights of the undertakings. Remedies affect their freedom of contract

and their property rights. In the same vein, their entitlement to a fair trial may be altered. Secondly, we may wonder what could be the undesirable collective consequences of a near from generalized recourse to these procedures. It may reduce the quality of the jurisprudence itself. Case law is a public good at the economic sense of the term. A commitment decision reveals a poor information compared to a prohibition decision. The disappearance of the adversarial stage of the procedure hinders discussions about the theory of damage, about the balance of the effects, and about the adequacy and the proportionate character of the remedies. Altering *the struggle for law* deteriorates the quality of the signal produced by the case law. It may have several consequences. A first one is to reduce the capacity of the different stakeholders to anticipate the decisions. It impairs the legal certainty attached to the legal rule definition and its implementation. By doing so it increases the dominant undertaking's propensity to opt for such procedures. Eventually, the higher the number of cases settled, the higher the possibility to observe the development of parallel case law, specific to negotiated procedures and all the more robust that it is not balanced by any judicial control exerted by the General Court and by the Court of Justice.

We might finally wonder if negotiated procedures under EU competition regulation do really imply an effective negotiation. We have noted that a commitment procedure is not a private contract that must be validated by a court as it is the case in the USA. The bargaining between the incriminated undertaking and the authority cannot be only conceived in a horizontal way. Indeed, there is a significant verticality at stake. The EU Commission is not a player as another one. The Commission benefits from a large margin of discretion in favoring this kind of procedure for a given case (through communicating competition concerns and not issuing a statement of objections). The Commission also decides unilaterally to accept or not the commitments proposed by the undertaking and to come back to an infraction decision.

The *Google Shopping*, *Android*, and *AdWords* cases are particularly striking. Considering that the initial negotiated procedure was unsuccessful

(e.g., that the commitments proposed by Google were not sufficient to address its competitive concerns), the Commission unilaterally decided to go back to an Article 7 procedure and to send in 2015 a statement of objections. Three procedures were launched. A first one led to the *Google Shopping* decision of June 2018 (with a €2.42 million fine). A second one came to the *Android* decision of July 2018 (with a €4.34 million fine). A third one, corresponding to *AdWords* related practices is still expected.

On the one hand, it tends to enhance the credibility of the Commission. Commitments are not suggested to dominant undertakings for weak cases, and the Commission demonstrates that it may refuse insufficient proposals. The Commission's behavior may be analyzed as a reputational investment. On the other hand, these decisions contrast with the Recital n°13 of Regulation 1/2003 according to which: "Commitment decisions are not appropriate in cases where the Commission intends to impose a fine." Negotiated procedures in antitrust appear more as a competition policy tool (with all the characteristics associated to public policy in terms of verticality) than a "contractualization" of the competition law enforcement in a pure horizontal logic.

Abstract

Neuro law and economics is a very young discipline that aims to study law and economics phenomena towards the help of neuroscientific techniques. These studies are the result of bringing together two different approaches that start from different disciplines in order to analyze, in particular, some aspects of the punishment. These two approaches are behavioral and experimental economics and the analyses deriving from the so-called neuro-law. These

two disciplines have been developed independently in the last decades and only in the last years they are jointly used to implement scientific analyses of punishment.

Introduction

Neuro law and economics can be considered as a very young discipline that studies law and economics phenomena towards the help of neurosciences. These studies can be seen as the result of bringing together two different approaches that start from different disciplines in order to analyze, in particular, some aspects of punishment. They implement some experimental and neuroscientific techniques. These two approaches are the studies of behavioral and experimental economics and the analyses deriving from the so-called neuro-law. These two disciplines – that incorporate interdisciplinary approaches – have been developed independently in the last decades and only in the last years they are jointly used to study some scientific phenomena. Then, we have to present these different approaches to understand what neuro (law) and economics is.

Behavioral and Experimental Economics

First of all, we present how the development of Behavioural and Experimental Economics allowed to shed light, among other topics, on the study of punishment in a very new perspective for economists. Let us consider a simple environment as the one represented in the ultimatum game, where we have the presence of two subjects that face a simple economic dilemma. The first player has to choose how to divide a given amount of money between himself and the second player. Then, the second one may or may not accept the choice made by the first one. If the second one accepts the monetary endowment is divided as the first player decided. If the second player does not accept the choice of the first one both the players earn an amount of money that is equal to zero. The classical economic theory predicts that the second player will accept each positive monetary offer from the first one, even if the offer is very

unfair. Moreover, the second player is indifferent between the acceptance or the rejection when the first player offers zero. Güth et al. (1982) show – using an the ultimatum game in an economic experiment – that people – the second players – are ready to reject a positive monetary offer if they consider it unfair, even if this choice reduces to zero their monetary endowment. Then, people are ready to spend money to sanction other people if they behave in an unfair way. In particular, Güth et al. (1982) show that people are ready to spend money to sanction an unfair action that damages them. This pioneering result has been confirmed by many other studies in the following decades, also with the implementation of different experimental protocol as the public good game with punishment (Fehr and Gächter 2000, 2002) and the trust – or the investment – game (Berg et al. 1995).

An important ancillary result has been reached after that a new experimental protocol using the third party punishment game has been developed. In his simplest version, in this game we have the presence of three players. A first player can decide how to divide a given amount of money between himself and a second player. After this choice, a third player must decide whether or not to sanction the first one if she/he thinks that the division between the first two players has been unfair. Obviously, the sanction has a positive monetary cost for the third player. Also in this case, the classical economic theory never predicts that a third-party will be ready to spend money to sanction an unfair behavior. As Fehr and Fischbacher (2004) show for the first time, people are ready to sanction an unfair behavior in this case also, even if it damages a person that is not the punisher. Then, they show that people are ready to spend money to sanction an unfair action even if they are not directly damaged by that. Also in this case, other studies confirm this result (see, for instance Henrich et al. (2006) and Marlowe and Berbesque (2007)) also in environments with the presence of a jury that acts as a third party (Ottone et al. 2015).

Obviously, the study of behavior related to sanction is really wide. For a survey on this topic and some suggestions for future research, the readers can refer the paper by Mulder (2016).

Neurolaw

Secondly, we have to present the development of neurolaw. In fact, law and science over time had to meet and to confront each other. Scientific discoveries have always raised a strong international juridical debate. From this meeting and clash between law and science, more or less suddenly, innovations and changes arise into legal system. Suffice it to think to legal issues about the declaration of human death or when we have before us a brain death. Other examples could be permission to use new informatics technologies inside the courtrooms or to use biological evidences such as blood or DNA trails.

Neurolaw stems from this continuous debate between law and science, particularly from Neuroscience.

Neuroscience is a discipline that studies the nervous system. It arises from the relationship of biology with medicine, psychology, mathematics, engineering, chemistry, thus evolving as an interdisciplinary science. Aim of neuroscience is to understand how the interconnections among single nervous cells (neurons) produce different perceptive and motors acts and different cognitive processes such as decision making or problem solving.

In the last years of 1900 different disciplines apparently unrelated to neuroscience begin to incorporate into their researches neuroscientific data and methodologies giving rise to new disciplines such as Neuroeconomic, Neuromarketing, or Neuroesthetics.

Neurolaw explores the effects of neuroscientific discoveries on legal rules (Petoft 2015) investigating law-relevant mental states and decision-making processes in defendants, witnesses, jurors, and judges.

Aim of law is to regulate individual's conducts, to respect human dignity, and to create a just and fair legal system. Moreover, law judges evidences about the causes of human behaviors, and neuroscientific study of human brain functions can make a very important contribution, so that the interaction/integration of neuroscientific discoveries in Law is inevitable.

The term “neurolaw” first appeared in 1991 in a scientific paper by Taylor et al. entitled “Neuropsychologists and Neurolawyers.” In this paper, Taylor and his co-authors analyzed how neuroscience, and in particular Neuropsychology, could provide probative data during a trial with defendants with cerebral lesions.

In subsequent years, thanks to the advent of new technique of neuroimaging such as functional magnetic resonance imaging (fMRI) or the not invasive technique of brain stimulation such as transcranial magnetic stimulation (TMS) and Transcranial Direct Current Stimulation (TDCS), the attention to neurolaw increased. In 2007, Law and Neuroscience Project was born from The John D. and Catherine T. MacArthur Foundation. The interdisciplinary project has the goals to help the legal system in order to avoid an improper use of neuroscientific evidence in some law contexts. Furthermore, it tries to deploy neuroscientific insights to improve the fairness and effectiveness of the criminal justice system.

The neuroscientific techniques usually adopted in neurolaw are electroencephalography (EEG), fMRI and TMS and TDCS. EEG is a not invasive technique which measures brain activity during the rest or during some cognitive tasks towards the information provided by superficial electrodes placed on various regions of the scalp.

fMRI is a correlational methodology which enables to detect the so called BOLD (blood oxygenation level dependent) signal. It is an indirect measure of neural activity and represents a small change in the levels of oxygenated red blood cell when a muscular or mental activity is performed. This technique is very useful because it is characterized by a high spatial resolution (the identification of volumetric area of 3 mm).

TMS and TDCS are causal methodologies, which enable to interfere with the cerebral activity and to observe functional changes. The first uses the electric field elicited by a magnetic field, and the second uses low intensity of electric current. Both have a moderate spatial resolution and TMS has an optimal temporal resolution.

It is possible to identify several topical areas on which the research of neurolaw scientists is focused.

Mind Reading or Lie Detection

To detect deception and truth in an individual is the dream of many judges. The use of lie detector tests has become a popular and legendary symbol from crime dramas to comedies to advertisements. The lie detector test provides for the use of three physiological signals recorded with a Polygraph: heart rate/blood pressure, respiration, and skin conductivity. Courts, including the United States Supreme Court, had repeatedly rejected the use of Polygraph because of its inherent unreliability.

Recently EEG method was employed in two forensic techniques: Brain Fingerprinting (BF) and Brain Electrical Oscillations Signature (BESOS) (for a description of these technique see Chauhan (2016) and Puranik et al. (2009)). The first was admitted in 2003 in a legal proceeding of Terry Harrington in Iowa. BF detects particular brain waves called p300. According to its inventor Lawrence Farwall (neuroscientist at Harvard university), these waves are correlated to memories of the past. Terry Harrington was sentenced to life for a murder, but defense subjected him to BF which resulted in a negative outcome, as if memories of the murder were not in his memory. Iowa District Court admitted BF test as scientific evidence and the murder case was re-opened. Later Terry Harrington was acquitted after the confession of a key witness. The case of Terry Harrington is the first and only one where a Court admitted the BF test. This is relevant because, although the BF has not been exposed to a peer review, its admission challenges previous judgment. This case is the proof that a neuroscientific evidence can influence the judge's decision making.

Different neuroscientific researches investigated the brain networks that underlie lie production (Meijer et al. 2016 for review). fMRI is the most used method and it is employed by several companies such as No Lie MRI. Some studies conducted by Daniel Langleben showed how lies are distinguished from truth by increased prefrontal and parietal activity (Langleben et al. 2005). Although numerous fMRI neurolaw researches on lie detection are continuing, the Courts still exclude fMRI lie detection evidence from trials. As an example, Judge Eric M. Johnson of the

Maryland Sixth Judicial Circuit had refused to admit potential exculpatory fMRI evidence during the murder trial of State v Gary Smith, claiming that "the use of fMRI to detect deception has not achieved general acceptance in the scientific community" (MacArthur Foundation 2016).

In fact, fMRI studies have different general limitations: because of its correlational nature, this methodology cannot be used to prove causation. When an fMRI study shows that a brain region is active when a person is trying to lie, one cannot exclude that the same brain region might be active because it is involved and activated during a state of anxiety or in any other cognitive processes. One meta-analysis study showed that the regions usually related to deception were the ventrolateral and dorsolateral prefrontal cortex, inferior parietal lobe, anterior insula, and medial superior frontal cortex (Christ et al. 2009). These brain regions are also activated during general executive processes as planning, working memory, and emotional process. Therefore, a limitation is to discern whether the neural activity measured by fMRI is associated with lying or with other neural processes. Moreover, many scientists argue that lie detection data recorded with fMRI are valid only within the context of controlled laboratory experiments, which often poorly approximate the real word.

Neuroscientists agree that more studies are needed before starting to use fMRI lie detection methodology.

Criminal Responsibility

Differently from fMRI, MRI was frequently admitted in courtrooms when it is relevant to obtain behavioral information correlated to specific brain pathologies. In 2007 a court of New York have authorized the scan of the defendant's brain, the popular journalist Peter Braunstein indicted of kidnapping and sexual assault. The defense intended to show that the brain illness "Schizophrenia" might have made it difficult for its client to control violent impulses. At the end of the trial, Braustein was utterly convicted: this case demonstrates how a neuroscientific evidence can be useful but not necessarily

lead to acquittal. Neuroscientific evidence could be able to indirectly address questions of intent in defendants with neurological or psychological illness that might reduce the ability of judgment during the crime. Another important contribution of neurolaw regards the brain development in adolescence. In fact, neuroscientific evidence has demonstrated that the adolescent brain has a slow development of the cerebral regions necessary for cognitive control as Prefrontal cortex (Blakemore and Robbins 2012). For this reason, adolescence is characterized by low risk aversion and impulsiveness. The contribution of neuroscience to law about the behavior of adolescents brought in 2005 the US supreme court to the abolition of the death penalty.

Another important contribution of neuroscience to law is represented by studies on memory focused on memory limitations. These limitations may affect not only witnesses but also juries.

Bringing Together Behavioral and Experimental Economics and Neurolaw

Now neurolaw researches also deal with neuroscience evidence to understand and to improve decision making of the judge. Human societies universally expect that criminals will be punished, usually by impartial third-party decision makers. Then, the integration of Neurolaw together with behavioral economics can use various experimental protocols to investigate the punishment. Obviously, paradigms commonly used by neuroscientist are those used by experimental economists such as the third-party punishment or the hypothetical crime scenarios. The first is the economic game presented before where a potential punisher, the third-party, observes how a dictator share an amount of money with a receiver. In this case he may choose to punish the dictator spending his money or he can simply observe the scene. In this case, neuroscientific tools can be used to observe what happens in the brain of the three players. In the second paradigm, the subjects make various decisions about some different scenarios where a crime can be committed. These paradigms are used together with neuroscientific

methodologies as fMRI or not invasive brain stimulation (TMS, TDCS) in order to investigate the neuronal underpinning of punishment. The data showed different brain networks, with an involvement of anterior Insula and dorsal and anterior cingulate cortex and Amigdala. This first network seems to be involved in the detection of norm violation (Sanfey et al. 2003; Krueger and Hoffman 2016). A second network is formed by medial prefrontal cortex, ventromedial and dorsomedial prefrontal cortex, posterior cingulate cortex, and tempo parietal junction. The second brain network connected to the first one is generally associated to self-monitoring, mentalizing (Bressler and Menon 2010), emotional processes related to the harm to the victim. Both networks are connected to a central executive network engaging posterior parietal cortex and dorsolateral prefrontal cortex. The central executive network underlies the final decision making and then selects a specific punishment, integrating the information processed in previous networks with the contextual facts as circumstances surrounding the crime. The neuroscientific evidence about punishment could elucidate the neuronal and contextual variables that can influence the decision making.

Moreover, Neuroeconomics, another neuroscientific discipline, helps the juridical system and several times neuroeconomic studies are borderline with neurolaw studies. Pisoni et al. (2014) in a TMS study assessed that fair or unfair economic decisions, and context, in terms of different interaction styles, may modulate the corticospinal excitability. Authors show that economic exchange, indeed, especially when imposed by only one part (proposer), can elicit positive or negative emotions according to the context in which it occurs, implying different moral evaluation and reactions. These results are very important for a legislator and for policy, because explore the people's reactions to injustices.

Future Developments

Although there are the a number of studies about legal decision making, lie detection, mind reading, and criminal responsibility, legal experts and

lawyers still try to understand the best way to integrate neuroscience, behavioral economics, and law. Today, the best neuroscientific data that neurolaw can deliver to law are the evidence about criminal responsibility of individuals with neurological diseases. Some neurological pathologies indeed can elicit different criminal behaviors, especially diseases caused by damage to frontal brain areas involved in control of instinctive behaviors and decision making. The other topics of neurolaw so far have not gained scientific validations external to laboratories. The law is good to be prudent. Anyway interdisciplinarity will lead us to the law of future.

Next-Generation Access Networks

Claudio Feijóo
Sino-Spanish Campus, Tongji University -
Technical University of Madrid, Shanghai, China

Abstract

Next-generation access networks refer to telecommunications infrastructures – and the

technologies that support them – able to provide final customers with data rates above 30–50 Mbps.

Synonyms

Ultrafast broadband networks; Ultra-broadband networks

Sometimes the “access” is missing and the term is used simply as “next-generation networks (NGN),” although strictly speaking NGN would refer to the whole infrastructure and not only to the part closer – the access – to the final user.

Acronym

NGAN

Definition

Next-generation access networks refer to telecommunications infrastructures – and the technologies that support them – able to provide final customers with data rates above 30–50 Mbps.

Reference Framework: Broadband and Economic Development

The rise of the knowledge economy has reinforced the role of telecommunications as a strategic investment:

... the ability to communicate information at high speeds and through various platforms is key to the development of new goods and services. Broadband enables new applications and enhances the capacity of existing ones. It stimulates economic growth through the creation of new services and the opening up of new investment and jobs opportunities. But broadband also enhances the productivity of many existing processes, leading to better wages and better returns on investment. (EC 2006)

Next-Generation Networks and Next-Generation Access Networks

Next-generation networks (NGN) are the supporting infrastructure of ubiquitous broadband.

They are defined as networks based on the Internet Protocol able to deliver multiple data applications – whether originally based on voice, data, and video – to multiple devices, whether fixed or mobile. In addition, the provision of applications is decoupled from networks facilitating the introduction of innovations (De-Antonio et al. 2006).

An NGN can be divided into two main parts (Knightson et al. 2005):

- A backbone transport network that interconnects the local nodes where data traffic from the final users is gathered to be switched and further transported. The backhaul from distant nodes to the core network is typically included as part of the backbone, although it is convenient at times to consider it separately (the so-called middle-mile).
- An access network that links final users with local nodes, the next-generation access network (NGAN), colloquially called the last-mile.

NGAN Requirements

There is nothing like a strict definition of the minimum access speeds provided by an NGAN or any other defining parameter. A tacit agreement at the industry level seems to put this figure at 50 Mbps or beyond, but to prove the vagueness of the case, there are no indications whether this number refers to both the upstream and downstream parts or it should be applied just to the downstream channel. Even less is mentioned about the quality of service-guaranteed data rates per customer. Also, while the above figure may represent as of May 2014 some consensus, there are a number of regulatory decisions and digital strategy plans that implicitly address figures from 30 Mbps to 100 Mbps; see the Digital Agenda Europe for 2020 as a main example. In any case, these figures are beyond conventional broadband capabilities and therefore the name of ultra-broadband networks.

Some sources provide a narrower definition in relation to NGN to include exclusively wired access networks which consist wholly or partly in optical elements and are capable of providing enhanced broadband access compared to services provided over existing copper networks.

According to this type of definitions, wireless networks are not part of NGAN; see below.

NGAN Technologies

In general, broadband access technologies can be classified by the physical medium into two major groups: wired (or fixed line) technologies and wireless technologies. The main wired technologies are based on fiber, coaxial, copper wire (or any combination of them), and power line. Wireless technologies can be either satellite based or terrestrial. Terrestrial wireless solutions can be either fixed or mobile. Due to their niche market prospects and limitations, power line communications, satellite solutions – or other recently proposed airborne solutions such as balloons – and fixed wireless are not usually accounted among the NGAN technologies.

Therefore, the list of NGAN technologies as of 2014 reduces to:

- *Fiber to the home (FTTH)*. In this technology fiber runs all the way to the customer premises from the local node. FTTH technology is the ultimate fixed solution, supplying the highest data rates possible per household (Kramer et al. 2012).
- *Fiber to the basement/building/cabinet/curb/node/premises (FTTx)*. FTTx is a generic term for those technologies which bring fiber from the central office closer to the subscriber. They come in many varieties depending on the termination point of the optical network. In all of these architectures, the fiber from the central office is brought down to a node where equipment is housed in a cabinet to convert signals from the optical network (fiber) into electronic (copper wire, wireless connection, or even coaxial cable). The main advantage of these solutions is reusing part of the existing legacy network.
- *Digital Solutions on subscriber loop (xDSL)*. From the point of view of the architecture of the technology, xDSL solutions are equivalent to FTTx solutions mentioned above, their only difference being the perspective adopted: from the copper wire or from the fiber optics side.

Among them VDSL is the most widely used technology over copper wire. With new technological developments able to increase data rates, copper lines will continue to be a strategic asset well into the midterm. Not only are they able to provide data rates that would fall into the NGAN category, but, in addition, they also allow for a smoother and more scalable path in the transition from existing broadband to FTTH.

- *Upgrade of cable television networks (DOCSIS)*. Typically cable networks use HFC (“hybrid fiber-coaxial”) technology. DOCSIS (“Data Over Cable Service Interface Specification”) is the name of the series of standards developed for high-speed data transmission over cable television networks with release 3.0, the most widespread as of 2014. In general it could be said that the role of cable networks is particularly relevant in the NGAN competition scenario as the only different infrastructure from those of historical telecoms operators.
- *4th generation mobile communications (4G)*. The case of mobile wireless is controversial regarding its inclusion into NGAN. Mobile technologies are approximately 3–5 years behind fixed technologies in terms of sustained data rates per user. However, they already deliver peak data rates well above 100 Mbps, and they are not far from reaching the 10 Mbps level per user with some consistency. Therefore, mobile broadband connections are considered here as a suitable (stand-alone or complementary) technological alternative to fixed access technologies. The most relevant technology is LTE, labeled as 4G by the International Telecommunications Union in 2010 (Ghosh et al. 2010). 4G plays a fundamental role: not only is it the cheapest solution for rural areas, but it can also complement or even replace fixed broadband in urban and suburban areas, especially as wireless technologies fit mobile lifestyles better.

NGAN Deployment

The choice of access technology is simply a matter of deployment costs (which in turn depend

basically on socio-demographics and geographic variables and possible reuse of existing infrastructures) and the user's requirements (and expectations).

Regarding the status of deployment, in general terms it can be said that as of 2014 NGAN is still in a relatively early stage of deployment – particularly out of main urban areas. In any case, the transition from copper to fiber access networks is underway, and it is expected to result in the replacement of most copper access networks over the next two decades.

Future Directions

From a technical perspective, future prospects for NGAN include some form of fixed-mobile convergence, where fiber networks will be complemented by heterogeneous wireless networks (Raychaudhuri and Mandayam 2012). The rationale is that no access technology enjoys the optimal characteristics for satisfying all the requirements demanded by users in every circumstance. Therefore, this case is leading operators to create platforms capable of integrating different access technologies over the same backbone network. The future market of the ICT sector, characterized by “comprehensive” operators, would be quite different from the current one, where there is clear separation between technologies.

From an economic perspective, the conditions for the deployment of NGAN are currently on the forefront of the debate about the role of telecommunication markets, the best regulation for them, the conditions for the return on investments, the type and level of competition, the requirements for sustained innovation, and the level and modes of potential public involvement (Bauer 2010).

No-Fault Revolution and Divorce Rate

Bruno Jeandidier

Bureau d'Economie Théorique et Appliquée (BETA), CNRS and University of Lorraine, Nancy, France

Abstract

Concomitantly with the no-fault divorce revolution in the United States, there has been an increase in the divorce rate. From this observation, the question emerged of whether divorce law had a neutral effect on divorce behavior. Economists have conceptualized the issue by using an approach based on the “Coaseian” negotiation process, comparing unilateral divorce to divorce by mutual consent. The theoretical model predicts the neutrality of the law. But in the case of divorce, these assumptions are questionable. A determination as to the neutrality or non-neutrality of divorce law can thus be made based on empirical analysis. Early empirical studies came to conclusions favoring neutrality, but little by little, as methodological controversies accumulated, those empirical conclusions became more refined. Finally, a certain consensus emerged that the revolution in divorce would seem to have had a positive short-term impact on the divorce rate on the one hand, due more to the transition to unilateralism than to the abandonment of any reference to fault, and to have had a negative effect on the longer-term divorce rate on the other, because divorce law reform would seem to have prompted better-quality marriages.

Introduction

The term “no-fault divorce revolution” comes from the United States. It originated in the debates that came about in the 1980s as one after another the various American states transitioned from at-fault divorce regimes to no-fault divorce regimes (about economic origins of no-fault

divorce revolution; see Leeson and Pierson 2017). This change in American civil law stirred fierce conflict between the advocates of traditional family law and advocates of more progressive and feminist positions. The origins of this polemic are doubtless to be found in the stir created in the media and the political sphere by the alarmist book by Weitzman (1985). Based on data drawn from California State divorce rulings, the author showed that the introduction of no-fault divorce in that state would seem to have resulted in declines in the standard of living for the average female divorcee that were far more significant than had been the case prior to divorce law reform. Subsequent work (including Peterson 1996) showed Weitzman's (1985) estimates to have been largely exaggerated; nevertheless the debate had been launched around the negative consequences of the no-fault divorce revolution. Parallel to questions about the estimation of consequences relative to the standard of living of ex-spouses following a divorce, the debate also focused heavily on whether or not this new divorce regime would in fact encourage divorce. In other words, was it the abandonment of fault as a condition of divorce that explained the increase in the divorce rate observed during that same period? Economists have seized upon this question, seeing it as an interesting application of the more general issue of the neutrality of law. Starting from the pioneering article by Peters (1986), the no-fault divorce revolution thus spread to scientific journals in economics and sociology as well, giving rise to a fairly extensive series of articles in which more recent articles challenged the preceding ones and so on.

Peters' Pioneering Article Establishes the Theoretical Framework for Economic Analyses of the No-Fault Divorce Revolution

For Peters (1986), and subsequently for other economists, the discussion does not center on the concept of fault in itself but on the decision-making process: unilateral decision versus decision by mutual consent. In a no-fault divorce

regime, either spouse may apply for divorce unilaterally on the grounds that he or she no longer wishes to live as a couple, even if their partner does not agree. In a fault-based divorce regime, an injured spouse cannot apply for a divorce if the offending spouse does not agree to it; mutual consent is required unless fault is proven in court. It was in particular the observation of frequent difficulties in proving fault (with negative effects) that led American legislators to abandon the at-fault divorce regime.

Peters (1986) then uses Coase's theoretical model as an analytical framework to express the hypothesis of the neutrality of the law in regard to divorce: under certain conditions, negotiations can be arranged between the spouses, resulting only in efficient divorces, regardless of the divorce regime in force. The divorce regime in force would therefore be considered neutral.

Broadly, and making a simplified use of the notation proposed by Peters (1986), the gain derived from marriage R can be expressed as follows:

$$R = M(1 - p) + E(A_f + A_m)p \quad (1)$$

where p is the probability of divorce, M is the benefit derived from living as a couple, and A_f and A_m are the estimated postdivorce opportunities for the wife and husband, respectively, with the following assumptions:

- M is fixed, known, and perfectly divisible.
- Although A_f and A_m are not known with certainty, each spouse is fully aware of the opportunities available to their partner (informational symmetry), and these postdivorce gains are perfectly divisible.
- A division of M was agreed upon at the time of marriage, attributing X to the wife and $(M - X)$ to the husband.
- The negotiations between the couple take place without transaction costs (because people in couple relationships know one another very well).

The divorce is thus a fairly simple matter: it will be an efficient divorce if $M < (A_f + A_m)$; the

husband will want a divorce if $(M - A_m) < X$, and the wife will want a divorce if $A_f > X$.

If both spouses want a divorce and the divorce is efficient, or, conversely, if both spouses wish to remain married and the divorce is not efficient, the question of the neutrality of the law does not arise. In the other two cases, the following reasoning will apply. The situation we will study will be one in which the husband wants a divorce but not the wife; the same reasoning may however be applied symmetrically, with the wife desiring the divorce and not the husband.

We will first look at a situation where the divorce would be efficient. If the divorce law in force is unilateral, the husband will ask for a divorce without taking his partner's negative opinion into consideration; this behavior is efficient. If, on the other hand, mutual consent is required, the husband will have to negotiate his wife's acceptance of the divorce: in an "at-fault" divorce regime, the spouse seeking the divorce thus negotiates the "right to remain married" held by the other party. The object of this negotiation is to grant compensation (C_f) to the wife in order at least to cancel out the loss that the divorce represents for her ($X - A_f$):

$$C_f = (X - A_f) + \alpha(A_f + A_m - M) \quad (2)$$

The negotiation therefore concerns α , a coefficient that represents the extent to which the husband is willing to share the gains to be obtained from the divorce with his former spouse.

Secondly, in the case of divorce by mutual consent, the husband will not be able to obtain the divorce if the divorce is not already efficient prior to negotiation, because the gains he will derive from the divorce will be insufficient to compensate for the loss the divorce will represent for his partner, and it will thus be efficient to remain married. In the case of unilateral divorce, the husband will request a divorce a priori, with no need for negotiation. However, the wife is still able to negotiate in regard to her husband's "right to divorce" and may in fact renegotiate the division of marriage gains X so that it is more in the husband's interest to remain married than to separate:

$$(M - X) = A_m + \beta[M - (A_m + A_f)] \quad (3)$$

Ultimately, whatever the divorce regime in place (unilateral or mutual consent), if negotiations are held under the assumed conditions (symmetry of information, no transaction cost, divisibility), the Coase model shows that only efficient divorce situations ($M < (A_f + A_h)$) will arise. Thus the negotiated compensation system makes it possible, on the one hand, to avoid the inefficient divorces that might occur under a unilateral divorce regime and, on the other hand, to successfully conclude the efficient divorces that in a mutual consent divorce system could be blocked by one of the two spouses. The particular type of divorce law in force would thus be neutral with respect to divorce decisions, and so, empirically, there should be no increase in the divorce rate associated with the change in divorce regime.

Are the Hypotheses of the Coase Model Suited to an Analysis of the No-Fault Divorce Revolution?

Peters (1986) acknowledges that the hypotheses of the Coase negotiation model may be strong in the case of divorce. On the one hand, it is quite possible that symmetry of information regarding postdivorce opportunities for each of the spouses ($A_m + A_f$) may not be respected (one strategy may consist in concealing this information, and such information may be costly to obtain). In this case, negotiation in the event of a unilateral divorce may result in the non-avoidance of inefficient divorces (insufficient negotiation of the share-out of marriage gains). And, in case of divorce by mutual consent, it is possible that efficient divorces may not be implemented (insufficient negotiation of compensation). If this is the case, an imperfect symmetry of information would lead to an increase in the divorce rate.

On the other hand, it is possible that marriage gains M may not initially be well known (at the time of marriage). In this case, in a unilateral divorce regime, since the wife cannot oppose the divorce and cannot expect to obtain compensation, it is possible that she will self-insure

(by making less of an investment in the domestic sphere), which is likely to reduce marriage gains M and hence increase divorce probability p . In this scenario, the type of divorce is thus not neutral with regard to the divorce rate.

Zelder (1993a, b) analyzes two other limitations of the thesis of the neutrality of divorce law in a discussion of two other hypotheses. On the one hand, the author shows that in the presence of transaction costs, the divorce law is not neutral. The author first studies the situation of unilateral divorce regimes, where transaction costs are much lower (even zero) than those in mutual consent divorce regimes. This is the hypothesis most often retained in sociological studies based on the fact that unilateral divorce is simple and inexpensive. In the context of efficient divorce, in the first case (unilateral), the wife is not able to fully induce the husband to remain in the marriage for lack of sufficient means (which is in line with the assumption of legal neutrality). In the second case (mutual consent), the husband cannot induce the wife to divorce because the transaction costs would absorb her divorce surplus. There would thus be more divorces under unilateral divorce. The author then proceeds to study situations where transaction costs are prohibitive regardless of the divorce regime. In a unilateral divorce regime, if divorce is inefficient, the wife cannot induce the husband to remain in the marriage (whereas she could do so in the absence of transaction costs), and in a mutual consent divorce regime, the husband no longer has the means to induce his wife to divorce (in spite of his divorce surplus). There again, the divorce rate should be higher in unilateral divorce.

On the other hand, Zelder (1993a, b) also looks at the fact that marriage gains M may not be divisible and/or transferable (at least partially) between spouses, when said gains consist in a public good. Now, the primary marriage gain is often the child, who is, in fact, a public good. Under a unilateral divorce regime, when a child is present, even if the divorce is inefficient, the spouse who wishes to remain married will not be capable of inducing his or her partner to give up the divorce because their asset (the “consumption” of the child) is not transferable because it is

not divisible. Again, under this assumption of indivisibility, the divorce rate should therefore be higher in unilateral divorce regimes.

These studies show that the neutrality of divorce law, as conceptualized through the Coase negotiation model, is highly dependent on the assumptions applied in the theoretical model. Thus empirical observation must ultimately be used to attempt to make a determination in regard to the neutrality of divorce law, in an investigation of whether or not the divorce rate observed does depend on the type of divorce regime in force.

Empirical Controversies Regarding the Impact of the No-Fault Divorce Revolution on the Divorce Rate

Because the various American states adopted the no-fault regime on different dates, the United States has provided an exceptional natural experimental site to study the relationship between the divorce rate and the type of divorce regime. Again in his pioneering article, Peters (1986) empirically demonstrates that divorce law is neutral, based on data from the *Current Population Survey* for 1979. His demonstration is based first of all on the observation that, all matters being otherwise equal, the fact of residence in a state that had opted for no-fault divorce was not significantly related to the probability of having had a divorce in the 4 years prior to the investigation. Secondly, his demonstration is supported by the observation that, on the other hand, residence in a State that had opted for no-fault divorce was positively and significantly correlated with the amount of compensation obtained (child support, alimony, etc.), which would thus support the negotiation hypothesis of the theoretical model.

Allen (1992), using the same data as Peters (1986), then challenged this demonstration by advancing three methodological criticisms. On the one hand, the status of states that made changes to divorce legislation during the 4-year observation period would appear to be ambiguous. On the other hand, the categorization of States according to the classification “at-fault versus no-fault” would appear highly debatable,

insofar as there is a whole continuum of situations between strict at-fault regimes and strict no-fault regimes; for example, certain states had barred the attribution of fault for the submission of a divorce application but retained the notion of fault based on negotiations regarding the distribution of assets and compensation. This critique was also made by Brinig and Buckley (1998). Lastly, it would be a mistake to introduce State-based indicators into the specifications because of the correlation with the indicator “at-fault versus no-fault.” Taking these criticisms into account, Allen (1992) then shows that, contrary to the results obtained by Peters (1986), residence in a state that had opted for no-fault divorce is in fact positively and significantly related to the probability of divorce: the divorce regime would therefore not be considered neutral.

Peters (1992) responds to Allen (1992), accepting the first two criticisms and thus adopting the corrections proposed by Allen (1992) but rejecting the third criticism on the grounds that this specification allows consideration of an unobserved heterogeneity according to which it is possible that it was the States with the highest divorce rate that were the first to opt for a no-fault divorce regime (reversal of causality). In reassessing his model with two of the three corrections proposed by Allen (1992), Peters (1992) then reaches the same conclusion obtained in his original 1986 work, namely, that the type of divorce law is neutral with regard to the probability of divorce.

A year later, Zelder (1993a) published results based on different data (*Panel Study of Income Dynamics*). In the first estimate, the author confirms the conclusions reached by Peters (1992), by showing the absence of significant correlation between the probability of divorce and residence in a state that had opted for no-fault divorce. Then, in the second estimation, the author demonstrates the relevance of his public good hypothesis. To do so, the author crosses the indicator “at-fault versus no-fault” with an estimation of the public good (the share falling to the children – estimated based on expenditures for the children – in the total assets of the couple). The fact that this cross-variable has a regression coefficient that is

significantly positive thus shows that residing in a State which has opted for no-fault divorce would encourage divorce when there are children present: divorce law would therefore not be neutral for married parents.

Another controversy then arose among researchers no longer using individual data but divorce rate time series by state. Nakonezny et al. (1995), using average 3-year divorce rates, show that divorce law is not neutral, insofar as these rates, observed before and after the transition to the no-fault divorce regime, are significantly different. Glenn (1997) criticizes this approach on the grounds that these estimations need to be corrected taking into account the general trend in divorce rates; the author shows that the differences highlighted by Nakonezny et al. (1995) are actually four times lower. Rodgers et al. (1997) then respond to Glenn (1997), accepting his criticism and introducing a corrective to reflect the trend but asserting that the new version is not adequate to reverse their initial conclusion of the non-neutrality of divorce law. Brinig and Buckley (1998) arrive at an identical conclusion, with different specifications. Without going directly into the controversy opposing Glenn with Rodgers et al., Ellman and Lohr (1998) propose a more elaborate methodology for correcting the trend, by taking into account peaks occurring before and after the legislative reform (the wait-and-see effect before, the surge effect after); yet their conclusions are mixed, suggesting that each State has a certain specificity. Glenn (1999) then once again revived the controversy with Rodgers et al. by questioning the method they used to calculate the trend (linear, over 10 years), insofar as the general progression of the divorce rate was not linear; it in fact accelerated at the end of the period, which with a linear specification would result in the attribution of part of that acceleration to the divorce law reform. Finally, Rodgers et al. (1999) responded to this criticism by means of a rather lengthy graphical analysis carried out on a state-by-state basis, an analysis which does not, however, lead to a definitive conclusion.

The third wave of controversy primarily involved Friedberg and Wolfers. Friedberg (1998) gathered all prior criticisms so as to better

integrate them into his analysis of individual data: the issue of endogeneity, the issue of classifying states based on the types of divorce legislation in force, the issue of trend correction, etc. His conclusions are as follows: whereas on the one hand there would indeed seem to be an effect due to divorce law (the divorce rate was 6% lower in the States that did not make a change to their legislation), this impact would appear to have been due primarily to the transition to a completely no-fault divorce regime (when the notion of fault is partially preserved, the impact is weak), and the effect would seem to be fairly permanent (it was strong just after the reform and then strengthened over the next 2 years). Wolfers (2006) then criticizes Friedberg's (1998) specification, primarily from the perspective considering the fixed "state-year" cross-effect (which mixes the fixed per-state effect and the effect of the reform) and the observation window being too short to take the trend into account. From the perspective of the results, his primary difference with Friedberg (1998) is that while the effect of the reform would indeed appear to be significant immediately after its entry into force, this effect nevertheless stabilizes after 8 years and then declines. This conclusion is consistent with that of Gruber (2004), using aggregate data drawn from several successive population censuses. Divorce law would thus appear to be non-neutral in the short term but neutral in the longer term. Drevianka (2008) then adds nuance to this conclusion. By separating no-fault divorce reforms from unilateral divorce reforms (since the two concepts are not strictly identical), the author shows that in fact the latter type of reform has an impact on the probability of divorce, and not the former.

The studies conducted by Wolfers (2006) are significant, because they open up a new research question: why does the impact of the no-fault divorce revolution diminish over time? The studies conducted by Rasul (2005) and Mechoulam (2006) then demonstrate the double impact of divorce law: in the short term, a transition to no-fault (easier) divorce leads to an increase in the divorce rate, and in the longer term this effect is offset by a negative impact on the divorce rate. Indeed, divorce becomes less probable because

new marriages are of better quality (better, but later matches) in anticipation of the possibility of unilateral divorce easier to obtain and thus reducing marriage gains. In sum, the impact of the no-fault divorce revolution would appear fairly limited. In a certain way, 20 years later we came "full circle," since Peters (1986), in his pioneering article, had suggested that the no-fault divorce revolution could ultimately lead to a drop in the divorce rate if, anticipating an easier divorce and thus a conduct of self-insurance on the part of wives (synonymous with decreased marriage gains), behavior on the marriage market (marriage and remarriage) tended toward greater selectivity in matching.

The debate over the no-fault divorce revolution has not really crossed the Atlantic. Few studies have examined the neutrality of divorce law in Europe. The few European works were late in coming and therefore have benefited from the methodological advances made in North American studies. Taking up the methodologies used by Friedberg (1998) and Wolfers (2006) and applying them to 14 European countries experiencing divorce reforms between 1950 and 2003 (excluding countries that legalized divorce during this period), Gonzales and Viitanen (2009) conclude that in Europe, a transition to no-fault divorce would seem to have had a positive and permanent effect on the divorce rate, whereas a transition to unilateral divorce would seem to have had a short-term positive effect, fading after 5 years (results quite similar to those obtained by Wolfers (2006) for the United States). Kneip and Bauer (2009) confirm the latter results by conducting a similar analysis of 18 European countries for the period 1960–2003. These authors, however, contribute an original clarification, by distinguishing *de jure* unilateral divorce from *de facto* unilateral divorce. Divorce is *de facto* unilateral when mutual consent is no longer required at the end of a (usually short) separation period undertaken by the couple. They then proceed to show that, without calling into question the very short-term positive effect (on the divorce rate) of *de jure* unilateral divorce reform, the move to *de facto* unilateral divorce would also seem to have had a positive effect on divorce rates but a

permanent one. In sum, for the period 1970–1990, divorce law reforms in Europe would seem to account for one-third of the growth in the divorce rate (which grew by 2% in the same period), but would not at all explain the growth in the divorce rate before 1970 and after 1990. Bracke and Mulier (2017) discuss the classification of Gonzalez and Viitanen (2009) between no-fault divorce and unilateral divorce and propose to introduce in addition the reforms of procedure that make divorce easier. Reforms that reduce the duration of divorce proceedings (unilateral divorce being conditional on a period of de facto separation) would be also important. On the basis of data relating to Belgium and using a method of cointegration, they show that the reduction in the duration associated with the simplifications of 1994 had the same impact on the divorce trend as the introduction of unilateral divorce in 1974. They also estimate that a reduction of 1 month of legal divorce process would increase the divorce trend by 1.4%.

Conclusion

Economic analysis of the impact of the no-fault divorce revolution on divorce behavior has been a very interesting application, combining theory and empirical analysis, of the issue – very central to the economic analysis of law – of the neutrality of the law relative to individual behaviors. The refinement of econometric methodologies and the historical hindsight provided by the gradual accumulation of rich databases have led researchers to obtain nuanced conclusions, in particular by showing that the apparent neutrality of the divorce law relative to the divorce rate resulted, in fact, from the combination of a positive short-term effect and a negative longer effect (which is indirect, through marriage behavior). But as this revolution began to mature and the debate around the growth in the divorce rate was no longer really topical, other research questions emerged. How might divorce law impact negotiations with regard to specialization within couples, regarding premarital cohabitation, fertility, conjugal violence, female suicide, etc.?

Definition

Non-Market valuation is a set of techniques that aims at reflecting the economic value of changes, in the availability or quality, of goods and services that are not intended to be traded in the market (e.g., health care, education, environment). The objective is to estimate the impacts of these changes on one's utility and by extension on the social welfare, in order to manage these goods and services by considering their true value to society.

Economic Values

In a neoclassical perspective, goods and services are valued in a utilitarian framework, i.e.,

individuals are rational, have various categories of desires and wishes (e.g., food, housing clothes...), and are able to classify them according to their preferences. They aim at reaching a maximum level of individual welfare according to their income constraint (utility maximization under budget constraint). Moreover, individuals are able to value the impact of an additional unit of good on their own welfare, which is decreasing as the units aggregate (decreasing marginal utility law). In the end, the economic value of any good increases with its usefulness and scarcity.

Markets generate the value of all traded goods and services as relative prices. Prices are therefore very useful in comparing different effects, as they give some indications of goods and services relative scarcity. It is assumed that values may be reflected in individuals' willingness to pay (WTP) or willingness to accept (WTA) associated with a change in the availability or quality of the goods (see Table 1). The social value of goods is then the sum of the marginal utilities of each unit for all of its users.

In a nutshell, economic values are mainly:

- Anthropocentric, since only the contribution to human well-being is taken into account
- Instrumental, as it is based on the utilitarian setting of the consequences of choices and actions and not on intrinsic or “deontological” values
- Subjective, because the value depends on individual's preferences

Economic values are classically divided into two types of values that make up the total economic value (TEV), in particular for environmental goods and services: use values, which include the benefits derived by an agent from a direct or

Non-market Valuation, Table 1 Willingness to pay (WTP) and willingness to accept (WTA)

	Improvement	Damage
Willingness To Pay (WTP) to...	Benefit from	Avoid a
Willingness To Accept (WTA) to...	Give up	Offset a

Non-market Valuation, Fig. 1 Use and nonuse values. (Adapted from TEEB 2010)

an indirect use of the good or service at stake, and also a potential option value; nonuse values, which reflect ethical or altruistic preferences (see Fig. 1).

Why Using Non-Market Valuation?

When the market is distorted or when goods and services have no market, market prices are poor indicators of the true economic value. As a consequence, how can one assign a monetary value to changes of goods and services that are not intended to be traded in the market (e.g., health care, education, environment)? The conventional view would be that nonmarketed goods and services are priceless, and a purely market rationale would act as if they had no value, especially while considering externality mechanisms. To tackle this issue, economists have developed a variety of methods that allow the construction of monetary indicators to value loss or gain associated with changes in the availability or the quality of these goods or services (see section “[Nonmarket Valuation Techniques](#)”).

In terms of law and economics, nonmarket valuation plays a crucial role to provide information to support public and private decisions in a

cost-benefit analysis (CBA) perspective (Hanley and Barbier 2009), in particular regarding high probabilities of harm and environmental justice concerns (Hsu 2005). For the effects at stake to be co-measurable, they are usually monetarized. Nevertheless, we may note that as argued by Hanley and Spash (1993), this is merely a device of convenience rather than an implicit statement that only money is meaningful.

In addition, nonmarket valuation can also help in environmental and resource economics at:

- Fixing the level of conservation effort
- Highlighting priorities in cost-effectiveness analyses by answering the question: “what is the best use of one euro invested in conservation?” in *ex-ante* analysis
- Communicating on the magnitude of global issues to promote awareness to policy makers and the general public
- Evaluating offset amounts in *ex-post* analysis

Non-Market Valuation Techniques

Nonmarket valuation techniques are used to re-build individuals WTP/WTa towards changes

Non-market Valuation, Table 2 Nonmarket valuation techniques. (Adapted from Tardieu 2017)

Economic techniques	Description
Market costs approaches	
Avoided damage costs	Uses the costs associated with the mitigation of a damage as the proxy for the value
Replacement costs	Uses costs of replacing a nonmarket service as a proxy for the value
Opportunity costs	Explicitly considers the value that is lost in order to protect, enhance or create a nonmarketed asset
Production function	Focuses on the (indirect) input costs of a particular good or service for the production of a market good corresponding to the nonmarket one
Revealed preferences	
Travel cost method	Uses data on people's actual behavior in real markets that are related to an environmental good. For example, the behavior studied is the number and distribution of trips that people make to outdoor recreation sites as a function of the cost of a trip. The travel cost is the weak complement (a complementary marketed good) of the outdoor recreation value
Hedonic pricing	Weak complementarity is assumed between the price of a property and the quality of the surrounding environment. For example, the nonmarket value is revealed through observations on the demand of residential properties
Stated preferences	
Contingent valuation	Estimates values by constructing a hypothetical market and asking survey respondents to directly report their willingness to pay to obtain a specified good or their willingness to accept giving up a good
Choice modeling	Based on a hypothetical market where respondents have a series of choice tasks in which they are asked to choose their preferred option (including <i>status quo</i>). Each option is described in terms of a set of attributes describing the good (including a price attribute) presented at various levels according to an experimental design. The analysis of the respondents' choices is based on Random Utility Maximisation (RUM) theory
Secondary valuation technique	
Benefit transfer	Uses economic information collected at a given area (study site), at a given time to make inference on nonmarket goods or services in another location (application site)

in the availability or quality of nonmarketed goods and services (see Table 2).

These techniques can be either direct or indirect. Direct methods are based on observable costs (avoided damage costs, replacement costs, opportunity costs) or allow deriving values from existing markets of close substitutes or inputs (production function). Indirect methods are based on individuals' revealed preferences through a substitute market (hedonic pricing, travel cost method), on individuals' stated preferences on an hypothetical market (contingent valuation, choice modeling), or on value transfer regarding nonmarkets goods and services from locations with similar characteristics (benefit transfer). By definition, each method has its flaws, as they either rely on individuals which may be misinformed, on proxies that may poorly represent agents' behavior, or finally on markets in which prices are poor indicators of the economic

value. Moreover, all presented methods are not indicated to assess all types of values. For instance, nonuse values can be exclusively assessed by stated preferences methods. Last, revealed preferences methods are indicated for *ex-post* analysis, while stated preferences methods are suitable for *ex-ante* analysis.

Nonmarket Valuation Limits and Criticisms

Although nonmarket valuation plays a critical role to provide information to support decisions, this gives rise to conceptual and ethical issues especially with regards to environmental goods and services. These issues lead to limits and criticisms with regards to, respectively, anthropocentrism, which is at the core of value building, and how

heterogenous components of the total economic value (TEV) can be effectively aggregated; value discounting regarding future uses; and the spatial dimension of environmental goods and services valuation, including ecosystem services (Tardieu 2017; Roussel 2018). Furthermore, issues arise also in law and economics regarding how the information from nonmarket valuation can be used to value environmental damages and how suitable financial offsets can be defined.

With regards to anthropocentrism, some limits do appear linked to possible confusion between an intrinsic value of nature, independent of humans, and the one derived from marginal changes linked to individual preferences. Moreover, there is also a reluctance to add benefits and costs without reference to their social distribution. In terms of values aggregation, one of the main difficulties is related to the heterogeneity of the methods used to derive these values (see section “[Nonmarket Valuation Techniques](#)”), which can be considered as not directly comparable. For example, the aggregation of use values measured by revealed preferences and nonuse values measured by stated preferences is relatively tricky. Connected to these issues arise technical difficulties as double-counting or the simultaneous economic valuation of uses that are socially or technically mutually exclusive (e.g., wood provisioning service and regulation service regarding carbon sequestration from forests ecosystems), as well as the degree of substitutability between so-called manufactured capital and of natural capital.

If we now turn to value discounting regarding future uses, there is a choice uncertainty when taking time into account, particularly when we consider environmental issues with far-reaching consequences in the future. This has a twofold consequence on valuation (Chevassus-au-Louis et al. 2009): on the one hand, the costs and benefits linked to far-reaching consequences tend to see their weight in decisions reduced; on the other hand, there is an uncertainty on these consequences as well as the behavior and expectations of future generations. Accordingly, the selection of a discount rate can be justified following two main reasons: present preference and the decrease in marginal utility with higher incomes for future

generations. Discounting can also be ethically criticized because discarding far-reaching consequences may lead to neglect critical issues with threshold (e.g., biodiversity).

In addition, the spatial dimension has often been excluded from economic valuation, leading to results far removed from reality. For example, taking into account the spatial dimension of ecosystem services in environmental economics implies measuring these services (supply and demand) according to their spatial context. The ecosystem services supply is indeed influenced by spatial variables such as climate variables, topography, soil type, hydrological conditions (Nelson et al. 2009). Simultaneously, the ecosystem services demand changes depending on the location of the ecosystem providing this service as well as the location of the potential recipients, the number of substitutes, and the accessibility (Bateman et al. 2006). In brief, the value will be influenced by three variables: supply (quantity and quality), demand (number of beneficiaries, uses, socio-economic characteristics), and the spatial context (complementary or substitutes goods).

Last, one can wonder about the reliability of the information from nonmarket valuation and how this can be used to value environmental damages and to define suitable financial offsets (Thompson 2002; Carson et al. 2003). The famous example of the Exxon Valdez oil spill in 1989 then led to nonuse value loss ranging from \$2.8 billion to \$7.19 billion (Carson et al. 2003), whereas use values loss were evaluated \$5 million (Hausman et al. 1995). The ensuing debate with the Panel chaired by Kenneth Arrow and Robert Solow (Arrow et al. 1993) is thus an iconic illustration of controversies over the past decades and on-going debates on nonmarket valuation and Nature monetization (Gómez-Baggethun et al. 2010; Costanza et al. 2014).

Norms and Standardization

Abstract

The purpose of this chapter is to survey the academic literature on the economics of norms and standardization in the domain of administrative law and to synthesize their main themes. The chapter begins by introducing basic economic framework and continues addressing the issues of norms and tax compliance. Next, the chapter surveys some of the most important areas in the administrative law and economics literature. Topics include norms and environmental compliance, standards in traditional law and economics scholarship, the issues of norms, standards and regulatory functions of the state and the occupational health and safety standards and norms.

Definition

Standard is a written definition, limit, or rule, approved and monitored for compliance by an authoritative agency as a minimum acceptable benchmark. Standardization is a framework of agreements to which all relevant parties in an industry or organization must adhere to ensure that all processes associated with the creation of a good or performance of a service are performed within set guidelines. Standards occupy a middle position between information measures, representing low intervention and prior approval, representing high intervention. Standard is also the legal or social criterion that adjudicators employ to judge actions under particular circumstances. Standards provide a greater degree of flexibility to judges and allow them to consider fact-specific circumstantial evidence. Norms are behavioral regularities associated with a feeling of obligation supported by normative attitudes.

Introduction

One of the pathbreaking insights offered by the law and economics scholarship is the notion that contracts, laws, and all human relationships are, due to bounded rationality, positive transaction costs, and asymmetric information problem, necessarily incomplete. However, the legislator may choose the level of identified incompleteness of the enacted laws by formulating legislation with different degree of specificity. The law and economics literature refers to this choice as a choice between standards and rules (Luppi and Parisi 2011). Kaplow (1995) argues that legislator is actually, while choosing between rules and standards, balancing between *ex ante* or *ex post* content and should calculate costs associated with each option. Whereas Schäfer (2001) suggests that the use of rules rather than standards has the advantage of reducing corruption, concentrating human capital, and cutting down court delays caused by complex decisions. Obviously, his suggestion rests on an assumption that legislators are inherently less corrupt and better informed than judiciary. Moreover, one may argue that norms

and standards should be analytically seen as an economic institution developed to address the notorious positive transaction costs problem (Coase 1961; Marneffe et al. 2015) and the overwhelming market failures problem (Gómez-Barroso 2016).

According to the dominant law and economics scholarship quality standards which subject suppliers of goods and services to behavioral controls and which penalize those who fail to conform are the prevailing form of social regulation (Ogus 2004). Ogus in his encyclopedical work on economics of regulation stresses that standards have been applied, while pursuing different goals and employing different techniques, to a vast variety of commercial, industrial, and social activities (Ogus 2004). Standards can be subdivided into three categories which represent different degree of intervention: (a) target standards, (b) specification standard, and (c) performance standard. Extensive law and economics literature investigates different aspects of standards (more than 400 references) in relation to public interest justification, cost-effectiveness models for standard setting, legal formulation, and even, for example, on private interest considerations (Ogus 2004). Careful examination, however, reveals the lack of rigorous law and economics analysis of standards in narrowly defined administrative legal setting.

However, while one may argue that the economic role of standards in the domain of administrative law calls for further law and economics treatment, an overview of law and economics scholarship devoted to the study of norms reveals a vast amount of literature. McAdams and Rasmusen (2007) report that since the early 1990s, considerable scholarship in law and economics has turned its attention to norms. Numerous articles have addressed the power of social norms and their relevance for law (Ellickson 1991, 1998; Cooter 1996; Posner 2000a), have investigated the nature of norm's definition (Ellickson 1998; Picker 1997; Mahoney and Sanchirico 2003; Kaplow and Shavell 2002; Kahan 2001; Scott 2000), have shed the light on how norms work (Hirschelifer and Rasmusen 1989; Ellickson 1998, McAdams 1996; Buckley

2003), and have stressed the importance of norms to legal analysis (Posner and Rasmusen 1999; Epstein 2001). Moreover, there is an extensive scholarship on how norms affect welfare (Sunstein et al. 2000; Shavell 2002; Kaplow and Shavell 2002) and on the interaction between the law and norms (Posner 1996a, b; Shavell 2002). Furthermore, extensive law and economics scholarship addresses the specific application in the fields of tort law, contracts and commercial law, property, intellectual property, criminal law, family law, international law, and even constitutional law (McAdams and Rasmusen 2007).

In addition, norms have been fairly addressed also in the economic analysis of administrative law. For example, Hasen (1996) offers norms as a possible explanation for rational choice theories of voting behavior. Hasen argues that as with other types of socially beneficial behavior, individuals might receive small social rewards for voting or small sanctions for not voting, and hence voting rights might reflect the degree to which a community succeeds in socially beneficial behavior (Hasen 1996). Hansen suggests creation of a legal duty to vote and supplement informal, social incentives with legal sanctions (Hasen 1996).

Norms and Tax Compliance

Posner (2000b) started the discussion on whether strict enforcement of tax law is complementary with social norms and introduced a signaling as a compromise between the standard model and the approaches that try to make sense of social norms by complicating utility functions. His signaling model differs from the standard model only by introducing the plausible assumption that people have private information about their own tastes, including their discount rates (Posner 2000b). Posner's signaling model implies that if information were costless, social norms would not exist and consequently rejects the claim that social norms are internalized or that people feel guilty when they violate social norms (Posner 2000b). Lederman (2003) takes investigation further by exploring the relationship between enforcement

and compliance norms. She suggests that enforcement and compliance norms are complementary and that the enforcement can buttress norms-based appeals for compliance (Lederman 2003). Her study offers empirical evidence that there is a general societal norm of tax compliance in the United States but that, among certain groups, there may be a norm of noncompliance (Lederman 2003). She also suggests that enforcement will increase the number of people who obey the laws for prudential reasons (Lederman 2003). If one would create such a critical mass of taxpayers than the violation of the law will, according to Lederman (2003), it will create a disutility on the rest of population and hence create a tax payment incentive stream.

Norms and Environmental Compliance

The impact and interplay of norms have been also widely discussed in the relation to environmental compliance as part of general administrative procedure. Vandenberg (2003), for example, proposes a conceptual framework that accounts for the influence of norms on environmental decision-making and on corporate environmental compliance. Vandenberg assesses substantive norms of law compliance, human health protection, environmental protection, and autonomy and suggests that administrative enforcement policies should strive to harness those norms (Vandenberg 2003). Carlson (2001) analyzes types of the US local governments' strategies framed for inducing higher levels of individual environmental compliance. Local governments have actually, in order to achieve such targeted behavior, employed different novel forms of recycling. Carlson (2001), while assessing these new forms, argues that a lawmaker should focus on the policies that reduce the cost of recycling rather than those that try to change people's preferences. By employing such policies, lawmakers will, analytically speaking, make signaling more effective and will also introduce direct esteem toward those citizens that recycle their daily waste (Carlson 2001).

Standards in Traditional Law and Economics Scholarship

The traditional general economic rationale (outside contract law) for government involvement in standardization, as with several other government activities, has derived from the possibility of “market failure” and the public good character of standards. Left to its own devices, the market produces too little or too much standardization or standardization of the wrong sort (Swan 2000). Swan (2000) also points out that an important role of standardization is creation of a strong, open, and well-organized technological infrastructure that serves as a foundation for innovation-led growth. Standardization also increases competition and enable firms to reduce costs and increase quality. Standards might also spur the development of product and service markets that are based on the newest technologies (Swan 2000). Moreover, Swan (2000) also provides the most comprehensive source of estimates of the macroeconomic benefits of standardization and emphasizes the following ones as the most important: (a) competitiveness cannot be achieved by innovation alone, but requires efficient diffusion of innovation, and standardization plays a key role in that, (b) standards provide a positive stimulus to innovation, (c) standards contribute at least as much as patents to economic growth, (d) standards have a positive effect on trade and do not seem to act as barriers to trade, (e) international standards are more important than national standards in encouraging intra-industry trade, (f) standards enhance international competitiveness, and, finally, (h) the macroeconomic benefits of standardization exceed the benefits to companies alone.

Norms, Standards, and Regulatory Function of the State

It is well acknowledged that informal of formal norms, principles of conduct, tacit agreements, and standards play a pivotal role in the

coordination and harmonization of economic activity (Weigel 2006). Sometimes, as Weigel (2006) points out, norms and standards represent a framework for a more formalistic setup of legal rules, directives, and decrees. Such informal rules frequently delineate collective action which brings them into the domain of public law. As previously discussed standards and norms are instrumental in understanding of the most puzzling economic and social issues. Widespread technical standards and certifications which represent (or which should represent) a transaction costs minimizing mechanism could be, for example, listed as such examples, as such institutions that pursue allocative efficiency.

The most widely discussed regulatory regimes imposing standards are the ones of occupational health and safety, consumer protection/consumer products, and environmental pollution. In the domain of administrative law, Choi (1996) offers a two-period model (with merely two agents) and investigates the trade-off between ex post standardization and ex ante standardization. His model implies that in ex post period each user selects a technology from a random distribution of technologies (Choi 1996). Choi’s model actually identifies Nash equilibrium that indicates an excess of ex ante standardization and a deficit of ex post standardization if users choose to experiment in ex ante period.

Jeanneret and Verider (1996) in their subsequent investigation analyze conditions for compatibility in vertically differentiated demand where imported high-quality good compete with low-quality domestic good. They derive a range of tax rates which make it profitable for both suppliers to opt for compatibility. In such compatibility only and only the compatible goods will prevail. Jeanneret and Verider (1996) also note that these ranges depend on the size of the quality augmenting effect of compatibility. They also show that EU policies that subsidize switching costs are likely to fail if the subsidy scheme is not established before foreign and domestic firms decide on compatibility (Jeanneret and Verider 1996).

Moreover, such subsidy scheme has to be binding for a longer period so that policy is credible for the decisions horizon of the suppliers (Jeanneret and Verider 1996). Goerke and Holler (1998) interpret their insights and argue that EU standardization should show continuity. Goerke and Holler (1998) also argue that there might be a high potential for rent seeking in the organization of European standardization activities and standard setting. They stress the unwillingness of private agents to contribute to the financing of the standardization procedures as an obvious rent-seeking behavior's indicator. They also criticize the lack of financial arrangements on the side of EU commission and the lack of clearly assigned rights as the main sources of inefficient standard setting procedures (Goerke and Holler 1998). Hence, European Union, while providing an uncertain institutional framework (lack of exact duties, responsibilities, and influence in the standardization process) and while retaining the power to revert to detailed, interventionist standard setting, prevents companies, research institutions, chambers of commerce, consumer organizations, trade unions, and other stakeholders from making sufficient, standard-setting, commitments (Goerke and Holler 1998).

In addition, Weigel (2006) argues that the most crucial issue regarding norms and standardization in administrative law, that still awaits critical law and economics assessment, is the enforcement issue.

Occupational Health and Safety

The control of risks arising at the workplace occupies a special position among regulatory regimes and has a well-documented history (Thomas 1948). Ogas (2004) identifies the optimal loss abatement (optimal care) as the public interest economic goal of regulatory standards. He defines optimal care as the one where the marginal benefits equal marginal costs. However, as Ogas (2004) correctly observes, such an optimal care is rarely met. Employers have imperfect information of the risks involved in particular jobs and cannot

be assumed to make rational decisions. Hence, an unregulated market would rarely generate optimal safety standards of occupational health and safety. In order to mitigate identified market failures, administrative agencies developed several different regulatory strategies that should produce optimal occupational health and safety standards. The predominant strategy is the agency approach where an independent public agency is entrusted with the task of determining exclusively the standards which will correspond to the optimal level of care in the particular workplace circumstances. Agencies actually mimic the idealized labor market, taking into account also distributional considerations (Ogas 2004). Under the quasi-market approach the primary responsibility for setting the standards is entrusted to the employer. In such model, administrative agency plays merely a residual role and scrutinizes the standards emerging from such practices to verify that they are consistent with the goal of optimal safety (Ogas 2004). Such type of standard-setting attempts to foster market-type solutions and external, by administrative agency-imposed standards, is only enforced in the instances of failures of such a quasi-market approach.

Concluding Remarks

The traditional general economic rationale (outside contract law) for government involvement in standardization, as with several other government activities, has derived from the possibility of "market failure" and the public good character of standards. Standards have been actually applied, while pursuing different goals and employing different techniques, to a vast variety of commercial, industrial, and social activities. However, while standards and norms have been thoroughly addressed in more than 400 references in economic literature and also produced a vast amount of law and economics literature, the assessment of public/administrative law actually reveals surprising lack of systematic assessment. Identified gap in the law and economics of

standards and norms in the domain of administrative law opens doors for an extensive law and economics treatment that would offer sets of legal and economic arguments for an improved regulatory response.

Nudge

A Critical Perspective

Abstract

In recent years, the nudge approach and the choice architecture design have become popular in policy and academic circles. The aim of this entry is to present a general overview of the theory of nudges and a critical appraisal of its application to practice, in policy and program as well as in research design, also with respect to possible alternative approaches.

Following the publication of “Nudge: Improving Decisions about Health, Wealth, and Happiness” (Thaler and Sunstein 2008), the term *nudge* has entered the economic and juridical focus in relation to public policies. Nudge refers to the idea that people’s behavior can be mildly, or gently, pushed towards a certain course of action. As a result, nudge can be considered as a tool of political economics, using individual cognitive characteristics to stimulate people towards a positive action without restricting their freedom of choice. This is an alternative form of intervention to other government tools of public policies, such as incentives, rules, and constraints, or education and empowerment. The proponents of this theory consider nudge as a less coercive tool than regulatory efforts and incentive-based systems, although it is considered to be associated with better results if compared with free markets or traditional informative campaigns. The debate is

deeply connected with the debate on paternalistic policies and the regulation approach and is also tied with bounded rationality. However, the interplay between all these aspects makes the definition of nudge problematic. Thaler and Sunstein, indeed, propose a definition which is still not overwhelmingly accepted (Rebonato 2012).

Policies inspired by nudge appear to be cheap and have the advantage of being experimentally testable and measurable (even if these policies can be tied with cultural and political issues such as the effects of the electricity consumption). As a result, nudge represents a novelty in the field. On the other hand, however, the use of nudges in real-life situations may involve the need to lie (or at least hide something) about the aim of actions that people are asked to perform. This clearly represents a point against the use of nudges.

The nudge theory is built on behavioral economics and on the idea that people have a bounded rationality, often do not have well-defined preferences, and are subject to a number of biases which cause people to make choices not in their own interest, sometimes also against their voluntary will. As for willpower, several examples exist: the desire to save and study, to consume healthier food, or avoid gambling activities. The desired action can be frustrating when lack of willpower is in action (Elster 1979).

But nudge is also based on other aspects linked to the decision-making mechanism. In many situations, indeed, people do not have well-defined preferences and, therefore, decisions become more complex. When there is a lack of clear preferences or inability to perform statistical computations and follow logic rules, people seem to be guided by simple rules (i.e., heuristics; see Kahneman 2012) in order to save mental energies. Specifically, the rational system of decision-making appears to be challenged (and often won) by a more impulsive system, faster, which is guided by simplifying strategies, such as information availability (the ease with which the side of a problem can be visible), and would give rise to distortions and simple heuristics. These distortions and heuristics tend to lead to systematic errors. The rational system (i.e., system 2) is connected with conscious and deliberate

decisions, whereas the other system (i.e., system 1) is highly unconscious and automatic. As a result, aspects which characterize the context of choice such as the number of alternatives available to individuals, the order of presentation of these alternatives, the way in which the choice is presented and framed, the existence of a default option, or the presence of a status quo alternative, which are typically considered as apparently irrelevant features become significant.

Nudge is then added to the debate over human rationality and about the influences on the decision-making process. A rational agent, as described by standard neoclassical normative models (von Neumann and Morgenstern 1947), is not affected by nudge intervention. However, in real-life situations, people appear to be not so rational (Kahneman 2003). In particular, the way through which the choice is designed and presented, the architecture of choice, becomes relevant.

Accordingly, the same mechanisms connected with the systematic errors can be used to direct people towards more healthy behaviors.

Nudge, which in this view represents a development of behavioral economics, has been already anticipated by a series of papers on the framing effect which has been found to elicit certain types of choices, rather than others, that are not necessarily for the good of individuals (e.g., marketing purposes). In this case, knowledge about decision-making processes can be used to persuade people (see Cialdini 2001a, b). The relationship between behavioral economics, law, and public policies developed early, also thanks to Kahneman (e.g., Kahneman et al. 1998; McCaffery et al. 1995). More recently, Parisi and Smith (2005) review the various implications of behavioral and cognitive economics for the law, such as the possibility to use cognitive biases to develop an approach that could be more effective than using monetary and nonmonetary rewards and punishments.

The subtitle of Thaler and Sunstein's book, "Improving Decisions about Health, Wealth, and Happiness," mainly refers to the measures aimed at pushing the limits of willpower. In front of a plate of peanuts, people tend to not restrain and

eat, even when they do not want or do not need to. The act of pushing the plate in an unhandy place, which can be considered as a pre-commitment strategy, is an example of nudge. In their book, the authors suggest to take away the peanuts, but this appears to be a command-and-control form regulation, which is a mandate that cannot be avoided. This is in fact an example of the difficulty to define a nudge.

Moreover, the two authors propose simple examples of nudge that do not seem to improve individuals' well-being, at least in a direct and clear way. For example, the choice of an opt-in mechanism, rather than opt-out (i.e., explicit versus presumed consent), seems to increase organ donation rates because of the human tendency to remain at the status quo (Thaler and Sunstein 2008). The choice of a certain type of mechanism represents an example of choice architecture through which a public policy can be implemented and that can be considered as an alternative to public awareness campaign or strong enforcement. In fact, it seems to be true that nudging leaves margins of freedom to individuals and does not bind people to an action unless they have a clear opinion in one direction or another. People seem to be influenced by nudges when they have not a clear opinion and, rather, tend to conform to social norms and what they perceived as normality.

Considering the difference between various policies, this example shows the difficulty with the current definition of nudge but also the complexity of the discussion around the architecture of choice. A more general definition considers nudge as a tool for implementing public policies by means of behavioral economics.

Nudges' problems and critics come from different perspectives.

In their website, Thaler and Sunstein display the ballot used by Hitler as an example of bad nudge (Nudge Blog 2010). As stated before, nudge can indeed be used in order to persuade people to the right, as well as the wrong, direction. The problem is clearly that of understanding who decides what is the right/wrong direction. Thaler and Sunstein lead the main debate to the issue of strong paternalism and soft paternalism and to the

fairness of one approach over another. Strong paternalism assumes that the state knows and decides what is the best for people and then constrains them to have a coherent, consistent behavior. Strong paternalism is also connected with the idea of an omniscient legislator that acts rationally and is perfectly capable of using nudges and push people towards efficient behaviors. Soft paternalism, or libertarian, is instead based on the idea that we have to help people in getting their best interest in terms of well-being. Here is the heart of the debate between strong and soft paternalism and about the possibility to implement a soft, libertarian paternalism by means of a theory of nudges.

Meanwhile, the opponents of this theory consider nudge as a dangerous tool because, differently from more explicit and direct forms of regulation, it operates through unconscious channels (Kahneman 2012).

In line with other critical-oriented works, referring to different example of nudging, Rayner and Lang (2011) claim that nudge is not a new policy. In particular, they highlight how similar tools tend to deny the general idea of politics that requires informed choices and discussions, and deals with problems in an explicit and direct way. They also underline the fact that nudge can be applied to avoid taking actual choices (Rayner and Lang 2011).

Bovens (2009) precisely criticizes the lack of transparency of nudges and, particularly, the fact that choice architecture does not trigger real changes in individual preference or improve the use of willpower. More recently, Vallgård (2012) criticizes the libertarian paternalism and denies the possibility to find an ethical reason for nudge, at least from a libertarian perspective. Furthermore, nudge would be anything new.

The fact that the theory of nudges exploits the bounded rationality is also controversial. The definition of nudge given by Rebonato (2012) underlines this aspect, which is instead not corroborated by Sunstein (2014).

Is it really impossible to develop consciously accepted forms of nudge and then give legitimacy to this type of intervention? Loewenstein et al. (2015) warn their subjects of the presence of a nudge, and in particular of a default option, in

choosing between different medical treatments. The effect of the default option seems to persist, even when individuals are informed about its use. As a result, the effect was not necessarily connected with a lie.

Colander and Chong (2010) discuss instead about the benefits of giving directly to people, rather than to the government or an economist, the choice of being nudged to obtain the best result. This is the path to an actual libertarian paternalism, where individuals can freely choose their choice architecture.

A different criticism refers to the effectiveness and the strength of nudge. For instance, Loewenstein and Ubel (2010) address this question in an article published in the *New York Times*. The question was about the reduction of electricity consumption and the preference for a nudge, rather than an incentive-based intervention (i.e., by charging higher costs), to approach the problem. Does the fact that a particular nudge intervention has been found to have an effect in controlled experiments suggest that these effects can be observed in real-life situations? Even more important, does statistical significant results imply a real impact of nudge interventions?

This article also proves the importance of this issue, considering that it has been taken out of academic publishing and issued in one of the most important newspapers in the USA. In the UK, for instance, a nudge unit has been created. Furthermore, the Obama administration has pointed out the need for a wider use of behavioral economic techniques in the implementation of public policies.

But if people are wrong, is there a guarantee that the governments are not going to make similar errors? Other than ethical issues, with what legitimacy can they inspire paternalistic policies?

Grüne-Yanoff and Hertwig (2016) criticize the use of nudges in the perspective of an evolutionary rationality. After all, the bounded rationality is a critic to the economic mainstream which is considered as a reference point for a hypothetical rationality, one from which we go away. However, according to the evolutionary rationality, this critic should not imply that people make systematic mistakes and are basically unable to take

decisions. Moreover, people are not necessarily driven by nonmodifiable and unconscious mechanisms, as those represented by the alleged system 1. In certain circumstances, indeed, simple rules and heuristics can be smart and effective. In everyday life, we need rapid decisions and, differently from the theory, logic is not always applicable. Rather than rationality, we need the ability to survive and to be clever and also to interact with the environment. Errors can be made because the environment has changed over millennia, for human beings as well as other living creatures. Furthermore, errors can also depend from an incorrect way of framing problems. Specifically, the use of conditional probabilities in describing the Bayes' Theorem makes hard to handle it, even for experts. Considering the probabilities as relative frequencies can instead make people understand the actual risk they face, giving them an effective freedom of choice. Problems need to, and can, be formulated in a more clear and understandable way. The theory of nudge also moves from an idea of a mainstream behavior. That rationality is, however, not applicable to real life, which is instead characterized by different situations that cannot be simply described in terms of calculable risks and probabilities.

As a result, as an alternative to nudges, other authors propose the boost approach, whose aim is to extend people's decision-making skills and refine the decision-making environment rather than focus on distortions and biases. In particular, Grüne-Yanoff and Hertwig (2016) refer to nudge and boost policies as two different research programs. The first program is based on the analysis of systematic cognitive heuristics and biases, which are considered to result in poor choices, whereas the second is a simple heuristics program where bounded rationality is considered in its capacity, rather than inability, to produce good inference and choice.

Conclusion

Nudge is receiving an increasing and strong attention for both the development of the behavioral approach and the possibility (which the nudge

approach seems to offer) to realize low-cost public policies, whose effectiveness can be proven.

It is hard to believe that the political debate around the paternalistic approach can ultimately have a solution. Indeed, this is a long-term discussed issue and nudge tends to complicate, rather than simplify, its resolution.

The problem lies in the fact that different forms of nudge exist and each form is associated with different critical issues. At the same time, however, most discussions tend to simplify and take into account only specific examples.

Kahneman (2012) underlines how writing with a difficult-to-read font can focus attention and decrease the possibility of errors occurring in the solution of a problem. This is an example of nudge that increases the ability of people to influence for the better the relationship between individual well-being and choices.

Nuisance

Keith N. Hylton

Boston University School of Law, Boston, MA, USA

Abstract

This entry sets out the law and the economic theory of nuisance. Nuisance law serves a regulatory function: it induces actors to choose the socially preferred level of an activity by imposing liability when the externalized costs of the activity are substantially greater than the externalized benefits or not reciprocal to other background external costs. Proximate cause doctrine plays a role in supplementing nuisance law.

Introduction

Nuisance law has suffered from the difficulty scholars have encountered in attempting to codify it in the form of simple rules and to understand the functions that the law serves. Prosser (1971) once described nuisance as an impenetrable jungle, and the dearth of efforts to state it in the form of black letter rules suggests that this opinion has been shared by many legal scholars. The process of scholarly codification, that is, of taking a mass of seemingly inconsistent court decisions and generating from them a set of clear legal propositions, has been slow in the area nuisance law.

Scholarly codification and an understanding of function are likely to occur contemporaneously. When courts and legal scholars have a firm understanding of the functions of a legal doctrine, it is relatively easy for them to summarize it in the form of simple rules. For example, the “Hand Formula” of *US v. Carroll Towing* is a summary of the negligence test that reflects a widely accepted understanding of the function of negligence law.

In recent years, research has focused on the function of nuisance law. I will set out the functional approach here, which uses economic analysis to understand nuisance doctrine at a high level of detail (Hylton 2011).

Earlier efforts have been made to provide an economic theory of nuisance law. Most of those early efforts, stemming from Coase (1960), have relied on the theory of transaction costs to explain the functional distinction between nuisance and trespass law (Calabresi and Melamed 1972; Merrill 1985; Smith 2004). But the core of nuisance law consists of balancing tests and limitations on the scope of liability that are not easily understood on the basis of transaction-cost theory. These tests and limitations are better understood using externality analysis.

Far from being an impenetrable jungle, nuisance law is a coherent body of rules that serves a socially desirable function. Nuisance law optimally regulates activity levels. The law induces actors to choose the socially optimal level of an activity by imposing liability when the externalized costs (of the activity) are substantially in

excess of externalized benefits or far in excess of background external costs. Proximate cause doctrine plays an important supplementary role to nuisance doctrine in regulating activity levels.

Nuisance Law

A nuisance is typically defined as an intentional, unreasonable, nontrespassory invasion of the quiet use and enjoyment of property. Each one of these terms has a special meaning in the law. Most of the terms are easily understood in terms of their general use in tort law. However, the term “unreasonable” is the most tricky concept, because there is equivocal use of the same term in other parts of tort law.

Take, for example, the word “intentional” in the definition of a nuisance. Intentional in nuisance law has a meaning that is not very different from its meaning in other areas of tort law. Typically the defendant is guilty of an intentional nuisance if he is aware of the invasion. The law does not require the defendant to have set out to harm the plaintiff.

Similarly, nontrespassory has a meaning that is readily ascertainable from the tort’s case law. A trespassory invasion is one that displaces the plaintiff from all or some portion of his property. For example, a large rock that is thrown over to the plaintiff’s property displaces the plaintiff from the space in which it travels and ultimately lands. This can be contrasted with a nontrespassory invasion, such as smoke or noise, which does not displace or oust the plaintiff from any space on his property.

The difficulty arises with the term “unreasonable.” As a result, efforts to state nuisance law in the form of simple rules have been sparse and for the most part unsuccessful. The best known effort to codify nuisance doctrine is the Restatement Second of Torts § 826, 1977, which says:

An intentional invasion of another’s interest in the use and enjoyment of land is unreasonable if:

- (a) the gravity of the harm outweighs the utility of the actor’s conduct, or
- (b) the harm caused by the conduct is serious and the financial burden of compensating for this and similar harm to others would not make the continuation of the conduct not feasible.

However, the Second Restatement’s § 826 is of questionable value because it refers to the actor’s *conduct* rather than his *activity*. One can draw an important distinction between these terms. Conduct often refers to an action or a series of actions within a short time span. Activity refers more broadly to an occupation or a significant pastime. For example, batting a baseball is a type of conduct, while playing professional baseball is an activity.

The reference to conduct could easily lead readers to believe that Restatement § 826 is equivalent to the balancing test observed in negligence law – i.e., the Hand Formula of *Carroll Towing*. The balancing test known as the Hand Formula says that the defendant is negligent if he fails to take care in a setting where his additional care would have been less costly than the additional injury costs that would have been avoided by that care. The language of Section 826 is easy to confuse with the analysis required by the Hand Formula.

If, instead, “conduct” in Restatement § 826 is understood to mean “activity,” then it becomes difficult to understand how the balancing test announced in 826 should be conducted. How is it possible to compare the gravity of the victim’s harm to the utility of the defendant’s activity? Suppose, again, that we are talking about baseball. A ball is hit out of the baseball yard and injures a passerby on the street. How should one go about comparing the gravity of the victim’s injury to the utility of playing baseball? Because this is so difficult to answer, Section 826 provides little guidance to lawyers and judges.

Moreover, part (b) of Restatement § 826 implies that strict liability should be applied to any activity that causes a “serious” interference with the plaintiff’s use and enjoyment of property, provided that the activity would not be bankrupted by such liability. This implies, strangely, that a thinly capitalized activity has an advantage under nuisance law, because it appears to immunize activities that would be bankrupted by a claim for damages. The difficult question in nuisance law is how to balance the external risks and the external benefits of an activity, a question which Section 826 does not even begin to address.

The following test, based on Restatement Second § 520, provides a better summary of nuisance doctrine:

In order to determine if an invasion is unreasonable under nuisance law, the following factors should be examined:

- (a) Existence of a high degree of interference with the quiet use and enjoyment of land of others
- (b) Inability to eliminate the interference by the exercise of reasonable care
- (c) Extent to which the activity is not a matter of common usage
- (d) Inappropriateness of the activity to the place where it is carried on
- (e) Extent to which its value to the community is outweighed by its obnoxious attributes

In the remainder of this entry, I will set out the basic economic theory of nuisance doctrine and explain why it is generally consistent with these factors.

Economics of Nuisances

The literature on the economics of nuisance law can be divided into two branches. One is the *transaction-cost framework*, which began with Coase's discussion of nuisance in his famous article on transaction costs and resource allocation. The transaction cost approach emphasizes the functional differences between nuisance and trespass law and provides a positive theory of the boundary between nuisance and trespass (Merrill 1985; Smith 2004). It has also been applied to explain the law on priority, often described as "coming to the nuisance" (Wittman 1980; Snyder and Pitchford 2003).

The other branch of work on the economics of nuisance law can be labeled the *externality model*, which focuses on the regulatory function of nuisance law (Hylton 1996, 2008, 2010). The notion that liability rules can be used to control externalities has been well understood for a long time in the law and economics literature (Polinsky 1979). The externality approach offers a model of the function of nuisance liability and a positive theory

of the core doctrines of nuisance. The core doctrines examined under the externality model are those of intent, reasonableness, and proximate cause. I will focus on the externality model below and offer a few remarks reconciling the transaction cost and externality models at the end.

Activity Levels, Care Levels, and Externalities

The law and economics literature distinguishes care and activity levels (Shavell 1980). The care level refers to the level of instantaneous precaution that an actor takes when engaged in some activity. For example, an actor can take more care while in the activity of driving by moderating his speed or looking more frequently to both sides of the road. The activity level refers to the actor's decision with respect to the frequency or location of his activity. If, for example, the activity of concern is driving, it can be reduced by driving less frequently.

The invasions associated with nuisance law are external costs connected with activity level choices. Consider, for example, a manufacturer who dumps toxic chemicals into the water, as a byproduct of manufacturing. Suppose the manufacturer is taking the level of care required by negligence law (reasonable care), and, in spite of this, the manufacturing process leads to some discharge of toxic chemicals. In this case, the environmental harm is a negative externality associated with the manufacturer's activity level choice.

The framework below is of activities that impose external costs on society even when they are carried out with reasonable care (Hylton 2008). The question examined is how the law can regulate activity levels in a way that leads to socially optimal decisions.

The Economics of Activity Level Choices

Assume that there are two liability rules that can be applied to actors, strict liability and negligence. Under either rule, actors are assumed to take reasonable care.

For any activity, the actor engaged in it will set his privately optimal activity level at the point which maximizes his utility from that activity. That means the actor will consider the benefits

he derives from the activity as well as the costs and choose a level at which the excess of private benefits over private costs is at its maximum. If we let MPB represent the incremental or marginal private benefits to the actor from his activity, and MPC represent the incremental private costs to the actor from increasing the scale of activity, the actor will increase his activity level as long as the marginal private benefit of an additional unit of activity exceeds the marginal private cost ($MPB > MPC$). The privately optimal level of activity is the level at which the marginal private benefit to the actor is just equal to the marginal private cost ($MPB = MPC$).

The diagram labeled Fig. 1 can be used to illustrate this argument. Assuming marginal benefits diminish as the actor increases his activity level, the marginal private benefit schedule can be represented by a downward sloping line, as shown in Fig. 1. The marginal private cost schedule is assumed to increase as the actor increases his level of activity (see MPC in Fig. 1). The reason for this is that the incremental cost of the activity goes up as the actor increases his scale. For example, if the activity is driving, the upward-sloping MPC schedule assumes that it is more costly to go from 50 miles per week to 51 than to go from 10 miles per week to 11. (Of course, this assumption may

not be valid in some cases. The incremental cost of going from 50 to 51 miles per week may be the same, in some cases, as the incremental costs of going from 10 to 11, but the results of this analysis are not dependent on this assumption of increasing marginal cost.)

The actor's privately optimal activity level choice is given by the intersection of the marginal private benefit and marginal private cost schedules, shown by point A in Fig. 1. At the intersection point, the net benefits (excess of private benefits over private costs) are at its maximum.

Now I introduce externalities. On the cost side, there are negative externalities (or external costs) associated with many activities. Consider, for example, driving. With each mile driven, the actor imposes some risk of harm from an accident or from pollution on the public in general. Or, if the activity is manufacturing, with each widget produced, a manufacturer who discharges chemicals in the water imposes cleanup costs on others. The marginal social cost of the actor's activity is simply the sum of the marginal private cost and the marginal external cost imposed on society.

On the benefit side, it is possible that there are benefits to society generated by the actor's activity. In the manufacturing case, suppose that instead of producing widgets, the manufacturer is

Nuisance, Fig. 1 Activity levels and externalities

producing a vaccine for some communicable disease. Vaccines cast off substantial external benefits by reducing the risk of disease even to the unvaccinated. The marginal social benefit is the sum of the marginal private benefit and the marginal external benefit of an additional unit of activity.

The final step of this introduction to the economics of activity level choices is to consider the differences between private and social incentives. Consider the case of low externalities on both the cost and benefit sides. Suppose there are external costs and external benefits connected to the activity, but they are relatively modest. They are shown in Fig. 1 by *MSC (low externality)* and *MSB (low externality)*. The socially optimal level of activity, which equates marginal social benefit and marginal social cost, is found at the point *B* in Fig. 1. The socially optimal level of activity (*B*) is roughly the same as the privately optimal level of activity (*A*). The reason is that the modest positive and negative externalities cancel each other out. Given this, there is no reason for the law to intervene to try to reduce the level of activity.

The case just considered is similar to that of an “irrelevant externality” (Buchanan and Stubblebine 1962; Haddock 2007). Although there is an external cost, society should not try to correct it because there is an offsetting external benefit. Buchanan and Stubblebine emphasized the case of offsetting internal benefit, but the concept of an irrelevant externality is equally valid if there is an offsetting external benefit.

Now consider the case of high externality on the cost side and low externality on the benefit side. This is shown by the intersection of the *MSC (high externality)* and *MSB (low externality)*, point *C* in Fig. 1. In this case there is a wide divergence between the privately optimal level of activity (point *A*) and the socially optimal level of activity (point *C*). This case is one in which it appears desirable for the law to intervene to reduce the level of activity. Indeed, in the case of very high externality on the cost side (see *MSC (very high externality)*), it may be desirable to shut down the activity completely.

Consider lastly the case of low externality on the cost side and high externality on the benefit

side. The intersection of the marginal social cost and marginal social benefit schedules occurs at point *D* in Fig. 1. In this case, the privately optimal level of activity (*A*) is substantially below the socially optimal level (*D*). The law should intervene to increase the actor’s level of activity.

Law

I have considered external costs and external benefits associated with activities conducted with reasonable care. Since the actors are assumed to be exercising reasonable care, the negligence rule cannot influence their activity level choices. The negligence rule holds the actor liable only when he fails to take reasonable care.

Strict liability has the property that it imposes liability on actors even when they have taken reasonable care. The legal system can regulate activity levels through imposing strict liability. This part examines the conditions under which strict liability leads to optimal activity levels.

First, consider the case in which externality is high on the cost side and low on the benefit side. The socially optimal scale is point *C* in Fig. 1. In the absence of strict liability, the privately optimal scale is point *A*. Imposing strict liability on the actor is desirable in this case. When strict liability is imposed on the actor, his marginal private cost schedule becomes equivalent to the marginal social cost schedule.

In the case of high externality on the cost side coupled with low externality on the benefit side, the actor’s privately optimal activity level under strict liability will be point *E*. It is not exactly the optimal level, which is at point *C*, but it is close. Social welfare will most likely be improved by using liability to lead the actor to produce at scale *E* rather than at the socially excessive scale *A*.

Consider the case in which externality is low both on the cost and on the benefit side. The socially optimal scale of activity is associated with point *B*. The privately optimal level of activity is associated with point *A*. These are the same activity levels. If strict liability is imposed on the actor, it will reduce his activity level below the socially optimal scale and therefore reduce social welfare. Strict liability will cause the actor to

choose the scale F , which is below the socially optimal scale.

This analysis implies that *strict liability is desirable only when the external cost of the actor's activity substantially exceeds the external benefit associated with the actor's activity*. In this case imposing strict liability reduces activity levels to a point that is closer to the socially optimal scale than would be observed under the negligence rule. When the external benefits are roughly equal to or greater than the social costs associated with the actor's activity, strict liability is not socially desirable.

Another case in which strict liability is not socially desirable is observed when two actors cross-externalize equivalent costs. Put another way, *when the costs externalized by two actors to each other are reciprocal, strict liability is not socially preferable to negligence*. The reason is that under strict liability, you will pay for harms to others, while under negligence (when everyone is complying with the negligence standard), you will pay only for the harms you suffer. Since those harms are the same, activity levels will not differ under the two regimes (Hylton 2008, 2011).

Application to Law: Nuisance and Abnormally Dangerous Activities

To this point, I have presented a model of the economics of externalities and considered its implications for law. In this part, I will examine the extent to which the law conforms to the predictions of the model.

Abnormally Dangerous Activities

The most straightforward application of this model is to the law of abnormally dangerous activities (e.g., blasting). To determine whether an activity is abnormally dangerous, Section 520 of the Restatement (Second) of Torts provides the following factors:

- (a) Existence of a high degree of risk of some harm to the person, land, or chattels of others
- (b) Likelihood that the harm that results from it will be great
- (c) Inability to eliminate the risk by the exercise of reasonable care

- (d) Extent to which the activity is not a matter of common usage
- (e) Inappropriateness of the activity to the place where it is carried on
- (f) Extent to which its value to the community is outweighed by its dangerous attributes

The provisions of Section 520 are in line with the theory set out in the previous part of this entry. First, note that Section 520 can be divided into two parts, the first three provisions and the last three provisions. The first three provisions govern the degree of residual risk and imply that strict liability for operating an abnormally dangerous activity is appropriate only when the residual risk – the risk that remains after the actor takes reasonable care – is high. If the residual risk of the actor's activity is high, strict liability may be appropriate. On the other hand, if the residual risk is relatively low, strict liability would be inappropriate under Section 520. Judge Richard Posner famously applied this component of Section 520 to hold that strict liability would be inappropriate in *Indiana Harbor Belt Railroad Co. v. American Cyanamid Co.*, 916 F.2d 1174 (7th Cir. 1990).

The final three provisions of Section 520 line up with the language in *Rylands v. Fletcher*, L.R. 3 H.L. 330 (1868), which provides the foundation for the law on abnormally dangerous activities. The third factor, common usage, helps us identify activities for which the risks are reciprocal to those of other common activities. If an activity is one of common usage, then actors engaged in those activities will impose reciprocal risks on each other, and there is therefore no basis for adopting strict liability over negligence. The fourth factor, inappropriateness, is another way of determining whether the activity imposes a reciprocated risk. The last provision, comparing benefits and risks, guides courts to compare the external benefits thrown off by the activity with the external costs. If the external costs are great relative to the external benefits, strict liability is appropriate under this provision.

Consider an example. If the actor holds a lion as a pet in his backyard, he will inevitably impose a great risk on his neighbors. Moreover, it is a risk

that remains great even after the actor has taken reasonable care. For this reason, holding a lion as a pet satisfies the first three elements of the Section 520 strict liability test. The last three elements are also satisfied. Holding a lion as a pet is not a common activity – the risk the lion holder externalizes to his neighbors is not equivalent to the risk they externalize to him. The benefits externalized to neighbors from holding a lion as a pet are likely to be far less than the risks externalized to them. For these reasons, it is appropriate under the theory presented here and under Section 520 to apply strict liability to the activity of holding lions as pets.

Nuisance

The law on abnormally dangerous activities is the most obvious application of the theory of this entry. However, the theory applies equally well to nuisance law, the subject of this entry. Most of the standard environmental interferences, such as air or water pollution, have been treated as nuisances under tort law.

The theory of this entry suggests a clear interpretation for the rules governing nuisance law. First, consider the basic legal definition of a nuisance: an intentional, nontrespassory, and unreasonable invasion into the quiet use and enjoyment of property. Intentional, in nuisance law, has had a meaning very similar to its use in the context of trespass law: it is enough if the defendant was aware of the nuisance. There is no need, on the part of the plaintiff, to prove that the defendant aimed to harm the plaintiff. The term nontrespassory has always had the effect of distinguishing between invasions that interfere with exclusive possession of property or a portion of it (e.g., a boulder hurled onto the plaintiff's property) and invasions that merely make it less desirable to remain in possession of property (e.g., smoke).

Perhaps the most important term in the definition of nuisance is unreasonable. The theory of this entry suggests that the factors of Section 520 are equally applicable to nuisance disputes. Paraphrasing Section 520, the appropriate test for unreasonableness under nuisance law can be articulated as follows:

- (a) Existence of a high degree of interference with the quiet use and enjoyment of land of others
- (b) Likelihood that the harm resulting from that interference will be substantial to the typical member of the community
- (c) Inability to eliminate the interference by the exercise of reasonable care
- (d) Extent to which the activity is not a matter of common usage
- (e) Inappropriateness of the activity to the place where it is carried on
- (f) Extent to which its value to the community is outweighed by its dangerous attributes

The first three factors of this test require that the interference be substantial even when the actor is taking reasonable care. As in the case of abnormally dangerous activities, the first three factors should be treated as minimal requirements for nuisance liability.

The last factor asks the court to compare the benefits externalized by the activity and the costs externalized. When the benefits are substantial, the last factor suggests that the court should be reluctant to impose liability on a nuisance theory. Consider, for example, the noise generated by a busy fire station. The noise generated by fire trucks constantly moving in and out of the station with their alarms running could be deemed to substantially interfere with the quiet use and enjoyment of land by neighbors. However, the neighbors also benefit by being located close to the fire station. Since those benefits are substantial and widely dispersed, the neighbors should not be allowed to impose strict liability on a nuisance theory against the fire station, the conclusion reached in *Malhame v. Borough of Demarest*, 392 A. 2d 652 (Law Div. 1978). There is no economic basis for using liability as an incentive to force the fire station to reconsider its location decision.

Nuisance law does not provide for compensation to the extra-sensitive plaintiff (*Rogers v. Elliott*, 15 N.E. 768 (Mass. 1888)). The justification for this well-settled piece of the law is best understood in terms of the model of this entry. A nuisance exists, under the model here, when the externalized costs associated with an activity are

substantially in excess of externalized benefits. The comparison of externalized costs and benefits is made with respect to statistical averages, not to any particular plaintiff. If, on the basis of statistical averages, the externalized costs associated with an activity are not substantially greater than the externalized benefits, then the activity is not a nuisance under the theory here. If a particular plaintiff suffers a severe injury under these conditions, that harm may be actionable under some other legal theory, such as negligence, but it is not actionable under nuisance law.

Local conditions play an important role in nuisance law. In particular, the last three factors (d, e, and f) of the test proposed here depend on local conditions. Most environmental pollutants are regulated because of the risk of harm they impose on people located near the source. In most cases, the risk of harm declines as people move further from the source. Thus, externalized costs are likely to be substantial near the source and declining to zero as one moves further away. Strict liability provides incentives for the pollution generator to locate in regions in which externalized costs are insignificant.

Under the proximate cause rule, courts have limited the scope of nuisance liability to injuries that are connected in a predictable way to the externalized risk. Injuries that are not predictably related to the externalized risk are not within the scope of strict nuisance liability. The externality model suggests a reason for this: to focus liability on the cost-externalizing features of the defendant's activity rather than the activity per se. Suppose the victim drives his car into the defendant's malarial pond. To permit a strict liability action would fail to tax the defendant's activity for the specific risk creation – i.e., the risk of malaria – that nuisance law aims to discourage.

A clearer justification for the proximate cause rule in nuisance law can be based on the model of the previous section. Let the externalized risk component be separated into two subcomponents, where one is the normal risk externalized by activities of the defendant's type and the other is the extraordinary risk that makes the defendant's activity a nuisance. For example, in the case of a

malarial pond, the normal part is the risk externalized by any water storage, and the extraordinary part is the malaria risk. The proximate cause rule excludes liability for the normal-risk component. If, as nuisance law implicitly assumes, normal risks are balanced off by (normal) positive externalities, then excluding liability for normal risk leads to optimal activity levels.

The proximate cause rule leads to the social optimum in activity by excluding the normal-risk component as a source of liability. In terms of Fig. 1, the "low externality" cost increment (*MSC (low externality)*) is representative of the normal risk. If normal positive externalities are present, so that *MSB (low externality)* measures the marginal social benefit of the activity, the socially optimal activity level (assuming the risk consists of both the normal and extraordinary components) is that associated with point C. However, strict liability applied without any offset based on the proximate cause rule would lead the actor to choose the activity level associated with point E. Applying the proximate cause rule of nuisance law, which limits application of strict liability to those injuries attributable to the extraordinary risk, leads the actor to choose the socially optimal activity level (point C). Thus, the proximate cause rule improves on strict liability by leading to an optimal imposition of liability.

Coming to the Nuisance

Sometimes defendants argue that plaintiffs should not be able to recover because they "came to the nuisance." The coming-to-the-nuisance defense is valid in some cases but not in all. The theory of this entry provides a justification for the ambiguous treatment of the coming-to-the-nuisance defense.

Since the goal of nuisance liability is to optimally regulate activity levels, a victim's decision to come to the nuisance is certainly a relevant piece of information. The victim's decision to move is no different from the case of the buyer who contracts with a seller to purchase some item with a latent and dangerous defect. If the buyers are aware of the negative feature of the product, then the resulting market equilibrium would be

socially optimal. Similarly, if a smoke-belching factory sits alone in an area, and the victim moves next door to it, there would be no reason to view the factory's activity as socially excessive. In this case, the coming-to-the-nuisance defense applies.

There are two reasons that the coming-to-the-nuisance defense might not be desirable in this model. First, the victim may not have been aware of the offender's activity when purchasing his property. In *Ensign v. Walls*, 34 N.W.2d 549 (Mich. 1948), the defendant maintained dog-breeding business in the residential area of Detroit. The invasions (odors, noise, occasional escapes, filth) caused by the defendant's activity may not have been obvious to prospective residents; most probably became aware of the nuisance only after moving in.

The second reason the coming-to-the-nuisance defense may not be socially desirable is that the market for real property can be distinguished from most other markets for goods or services. Suppose the community consists of one smoke-belching factory and 99 residents. It is clear in this case that the reciprocal harm condition would not be satisfied; the background risks externalized by the residents would be trivial in comparison to the cost externalized by the factory. If the coming-to-the-nuisance defense were allowed, there would be no mechanism to control the activity level of the factory. The factory could double its level of activity without meeting any liability.

The justifications for the law on priority based on the externality model do not diminish the more traditional transaction-cost-based understanding. A rule favoring priority would encourage socially wasteful races and expropriation (Wittman 1980; Snyder and Pitchford 2003). Snyder and Pitchford (2003) distinguish their analysis from the seminal analysis of Wittman (1980) by noting that their model allows for the court to have limited information and for low transaction costs between the parties after the first move invests. Smith (2004) addresses nuisance law generally from the perspective of information costs, arguing that exclusion rules are favored by the law because they facilitate the production and disclosure of information.

Transaction-Cost Model Versus Externality Model

A complete economic model of nuisance law would consist of the transaction-cost model and the externality model, with the transaction-cost model used to explain the boundaries of nuisance law and the externality model used to explain its regulatory function. The foregoing analysis focuses less on the boundary question that has been the focus of transaction-cost analysis and more on the regulatory function of nuisance.

I have already noted some of the boundary questions examined under the transaction-cost model, specifically the choice between trespass and nuisance and the rule on priority. The transaction-cost model appears to be superior to the externality model as a theory of the boundary between nuisance and trespass law. However, both the transaction-cost and externality models provide justifications for the law's treatment of priority.

One other boundary question, unexamined so far, is the exclusion of protection under nuisance law for aesthetic interests, such as the right to sunlight or to a view of the mountains, *Fontainebleau Hotel Corp. v. Forty-Five Twenty-Five, Inc.*, 114 So. 2d 357 (Fla. App. 1959). The exclusion of aesthetic interests appears to be better explained by the transaction-cost model than by the externality model. It is obviously an externality, in the technical sense, when a landowner erects a fence that blocks the sunlight to another adjacent landowner. There is no reason suggested by the externality model for not treating the harm to the adjacent landowner as potentially a nuisance.

Under the transaction-cost model, there is a clear economic case for excluding liability for aesthetic harms. If aesthetic interests were protected by nuisance law, there would immediately be questions of information and proof. If one adjacent landowner can sue the owner of a hotel for blocking sunlight, why not allow other adjacent landowners? The transaction costs of resolving these disputes in the bargaining process would be enormous. On the other hand, if the law refuses to protect aesthetic interests, then the transaction

costs of resolving disputes would be much more manageable.

Conclusion

Nuisance law is complicated and covers a wide array of land use disputes. However, at its core, nuisance is simple. The law generates optimal activity levels by imposing strict liability when externalized risks are far in excess of externalized benefits or far in excess of background risks. Nuisance doctrine is consistent with this theory.

Optimization Problems

Roy Cerqueti and Raffaella Coppier
Department of Economics and Law, University of
Macerata, Macerata, Italy

Abstract

This issue deals with the conceptualization of an optimization problem. In particular, we first provide a formal definition of such a mathematical concept. Then, we give some classifications of the optimization problems on the basis of their main characteristics (presence of time dependence and of constraints). In so

doing, we also outline the standard techniques adopted for seeking solutions of an optimization problem. Lastly, some examples taken by the classical theory of economics and finance are proposed.

Definition

An optimization problem is a mathematical obstacle. Its overcoming leads to the identification of some quantities (optimal solutions), contained in a predefined set (admissible region), such that a given (objective) function is optimized (maximized or minimized). Optimization problems have remarkable relevance in the context of economics and law, since taking consistent decisions is associated to the implementation of optimal – in some sense – strategies.

The General Theory of the Optimization Problems

In the context of economics and law, decision makers should act under the guide of optimality criteria. Indeed, it is easy to understand that a decision might drastically undermine the outcome of economic policies or law statement. This said, it is important to develop optimization models and solve them.

In this issue *optimization problems* (OP, hereafter) are treated. Specifically, some classifications of

OP are proposed on the basis of their relevant features. Several clusterings of the huge set of the OP can be proposed. We here report the most important ones under the perspective of the applications. Moreover, the solution strategies for each class of OP are also discussed, having in mind that an optimization problem might not have solutions. In this respect, a warning is in order: OP can be very difficult to solve, and sometimes standard techniques are not sufficient for achieving a solution. The core of Operational Research is exactly the study of new methods for facing OP which are out of the main frameworks. Hence, nonstandard techniques are not treated in this report, even if some of them will be briefly mentioned. Some remarkable economic examples of OP are also proposed.

Classification of the OP

Perhaps, the most intuitive classification of the OP is the one grounded on the dependence of the problems on time and leads to the distinction between static and dynamic OP. More precisely, OP are *dynamic* when the objective function and/or the elements of the admissible region are time dependent, otherwise they are *static*.

The static case is the simplest one, and its treatment requires basic mathematical tools. To discuss static OP, a subclustering of them concerning the presence or the absence of constraints on the involved variables is needed.

Static OP are *unconstrained* if the objective to be optimized is a real-valued function f defined over the n -dimensional Cartesian space $\mathbf{R}^n$, and the optimal variables are searched on the entire set $\mathbf{R}^n$.

Now, assume that all the functions here presented are enough regular, and the derivatives used in the description of the static OP exist. Then the standard solution algorithm runs in two steps: first, the “candidate” optimal solutions are detected by posing the vector of the first partial derivatives of f (the *gradient of f*) identically null, i.e.,: by searching for the vectors $\mathbf{x}_0 \in \mathbf{R}^n$ such that *grad* ($f(\mathbf{x}_0)$) = 0 (*first order conditions*, and the $\mathbf{x}_0$ ’s are the *stationary points*); second, the candidates obtained in the first step are classified through the analysis of the sign of the *Hessian* $Hess(f(\mathbf{x}_0))$,

which is an $n \times n$ matrix containing the second partial derivatives of f and provides information on the convexity of the function f . Specifically, if $Hess(f(\mathbf{x}_0))$ has positive (negative) sign, then f is convex (concave) in a neighborhood of $\mathbf{x}_0$, which is a minimum (maximum) for f over $\mathbf{R}^n$ (*second order conditions*). When $Hess(f(\mathbf{x}_0))$ is indefinite, then second order conditions do not lead to the classification of the stationary point $\mathbf{x}_0$. In this case, $\mathbf{x}_0$ can be classified through a local study of the behavior of f in a neighborhood of it.

Static OP are *constrained* when the optimal variables belong to a proper subset $\mathbf{A}$ of $\mathbf{R}^n$, which is identified through a collection of analytical equations and disequations of the variable $\mathbf{x} \in \mathbf{R}^n$. This class of problems is treated similarly to the unconstrained case but with a remarkable difference: the introduction of the so-called *Lagrangian H* is needed. The Lagrangian is a function including in a unified term the objective f and the equations and disequations generating $\mathbf{A}$. The optimal solutions are then derived by setting the gradient of H equals to zero and then by classifying the stationary points through the study of the Hessian of H . It is worth noting that H is defined also by the introduction of some ancillary variables (the *Lagrange multipliers*), so that the stationary points of H are automatically included in $\mathbf{A}$. It is important to recall here Weierstrass’ Theorem, which can be in general formulated as follows: if $\mathbf{A}$ and f satisfy some properties, i.e.,: $\mathbf{A}$ is a compact (closed and bounded) set of $\mathbf{R}^n$ and f is continuous in $\mathbf{A}$, then the constrained optimization problem admits solutions.

For details and examples on static OP, refer to Simon and Blume (1994).

The dynamic OP are those more involved in economic application, in that they are able to fit with the evolutive nature of the reality. In the dynamic OP, a set $\mathbf{T} \subseteq [0, +\infty)$ collecting the time is introduced. The objective functional J depends on time $t \in \mathbf{T}$ and is optimized with respect to an n -dimensional function of the time t (the *state variable*), denoted as $\{\mathbf{x}_t\}$. Indeed, functional J is usually defined as the aggregation over t (sum over t if $\mathbf{T}$ is a discrete set; integral over t if $\mathbf{T}$ is a continuous set) of a time-dependent

function f which depends also on $\{x_t\}$. The way in which optimization is performed can be *indirect*, i.e., $\{x_t\}$ and J are optimally selected by controlling a further set of variables $\{\alpha_t\}$ included in their definition (the *control variables*) or *direct*, otherwise. In the former case, we define the *optimal control problems* (OCP, henceforth), which is a very relevant class of the dynamic OP.

To fix ideas, assume that time is continuous, and $\mathbf{T} = [t_1, t_2] \subseteq [0, +\infty)$.

Under an operative point of view, the strategy for solving OP in the “direct case” is similar to that presented for the static OP. The role played in the static situation by the stationary points is assigned in the dynamic setting to the so-called *extremals*. In details, under the necessary regularity condition, the first order conditions can be rewritten through a special differential equation (*Euler equation*) of f . The extremals are then classified by studying the convexity of f through the Hessian matrix of the second derivatives of f . This procedure is theoretically formalized in the *Calculus of Variations*, and an illuminating overview on it can be found in Kamien and Schwartz (1991).

For what concerns OCP, their main ingredients are: the state variable $\{x_t\}$, which evolves accordingly to a differential equation (state equation); the control variable $\{\alpha_t\}$, managed by the decider in order to solve the optimization problem; the admissible region, which is a functional set containing the control variables; the objective functional J ; the *value function* V , which is the optimized objective function; and, lastly, the *optimal strategies*, which are given by the pair optimal controls-optimal paths.

A further clustering of OCP can be properly identified, on the basis of the presence of randomness in their formalization. So, we have *deterministic* OCP and *stochastic* ones. The latter are those where f , $\{x_t\}$ and $\{\alpha_t\}$ are random, while all the ingredients of the former are deterministic. In stochastic OCP, the state variable obeys a stochastic differential equation.

The procedures for solving deterministic and stochastic OCP are basically two: the *Pontryagin maximum principle* and the *dynamic programming theory*. The former method may be viewed as a generalization of the procedure employed for

solving the dynamic OP. Indeed, Pontryagin’s Theorem states that the optimal strategies are couples optimal controls-optimal paths which must optimize a special function (the *Hamiltonian*) similar to the Lagrangian of the static OP case and including the objective functional and the constraints. Moreover, the introduction of additional variables (*costates*) and the fulfillment of further conditions (*costate equations*) are also required; the latter method is based on the definition of the value function, which is proved to be formally the unique solution of a specific differential equation (*Hamilton-Jacobi-Bellman equation*, *HJB*) by means of a maximum principle (the *Dynamic Programming Principle*). If the value function is so regular to be the true solution of the HJB, then one can derive the optimal strategies through a *Verification Theorem*. It is worth noting that the regularity of the value function is an important aspect to be treated in the dynamic programming approach, and the employment of a concept of weak solutions of the HJB (the so-called *viscosity solutions*) is often required.

For a survey on the OCT and, in general, on the dynamic OP, see Fleming and Rishel (1975), Bardi and Capuzzo Dolcetta (1997), Yong and Zhou (1999), Fleming and Soner (2006), Kamien and Schwartz (1991). The concept of viscosity solutions is introduced and discussed in Fleming and Soner (2006) and Crandall et al. (1992).

Examples of OP

Some classical examples of OP can be listed in the field of economics.

In Markowitz (1952), the future Nobel Laureate Harry Markowitz developed an optimization model for the selection of the best *capital allocation* among a set of risky assets. The optimality criterion is based on the evidence that an investor aims at maximizing the expected return of a portfolio and, simultaneously, at minimizing its risk level. The resulting problem is a static constrained one, with convex objective function.

In the field of decision theory, a relevant role is played by the concept of utility. A utility function is a tool for ordering preferences of goods and is a

simple assignment of a number representing the satisfaction to be the owner of some quantities of goods. By conventional agreement, a greater value of the utility means a higher level of satisfaction. Hence, *utility maximization* is the ground of a number of static and dynamic OP. For some explicit models, refer to Mas-Colell et al. (1995).

A macroeconomic example of optimization model consists of the *maximization of the growth rate of a country*. In this case, the formalization of the related OP includes the evolutive nature of the phenomenon and the wide set of constraints. Hence, the OP are dynamic. The objective function is usually consumption or utility, and the constraints model human or physical capital accumulation. For this type of models, see Barro and Sala-i-Martin (2004).

Under a microeconomic point of view, of remarkable relevance is the problem of *cost minimization* and *profit maximization*. The solution of the resulting OP provides insights on the strategies to be implemented by the companies for improving their performances. Usually, such models are described through constrained OP, in order to capture the presence of budget and/or technological constraints. A detailed discussion on this family of OP can be found in Varian (1992).

Definition

The right (but not the obligation) to buy or sell a certain asset at specific moments in time at a predetermined price

Introduction

An option is a financial instrument that gives its holder the right to buy or sell an underlying asset at a pre-agreed price at specific moments in time (Hull 2011). The first feature of an option contract is that it gives the holder the right to do something, but not the obligation (Bachelier 1900). If an option entitles to buy an asset, the option is referred to as a call option, while a put option is the right to sell an asset (Brennan and Schwartz 1977). The pre-agreed price at which the holder can buy or sell the asset is the strike price or the exercise price. The time to maturity is the time period which indicates when the holder can exercise the option. When an option is exercised during the entire period, it is commonly referred to as

an American option, while a European option contract can be exercised only at the pre-determined expiration date (Cassimon et al. 2007). While the holder determines whether he or she is going to execute or exercise the option, the counterparty (the writer of the option contract) needs to deliver the asset to the holder at the pre-agreed price (in case of a call option) or buy the asset from the holder at the pre-agreed price (in case of a put option). The writer's action is thus dependent on the decision of the holder. For that flexibility, the holder of the option pays an upfront, non-refundable fee to the writer, which is called the premium, reflecting the market price of that option (Cassimon and Engelen 2016; Black and Scholes 1973; Cox et al. 1979; Merton 1973). One can find option contracts on a wide range of assets, including options on common stock (e.g., on a share of Google), options on a stock index (e.g., on the S&P-500, or the Euronext-100 index), options on currencies (e.g., on the EUR/USD exchange rate), options on commodities (e.g., on corn, cattle, soybeans), options on bonds, options on the weather conditions, etc. Options on common stock can also be part of the salary package of senior firm staff. Besides those financial options on a wide range of assets, the concept of options has also been applied in a business context (Cassimon and Engelen 2015; Cassimon et al. 2004).

Options are available on standardized option exchanges or tailor-made from financial institutions in the over-the-counter market. The most important option exchanges include the Chicago Board Options Exchange (CBOE), the CME Group (a merger between the Chicago Mercantile Exchange and the Chicago Board of Trade), the Philadelphia Stock Exchange (now part of NASDAQ), Eurex, NYSE Derivatives (Intercontinental Exchange), the National Stock Exchange of India (NSE), the Bombay Stock Exchange (BSE), and Bovespa. The most traded index options in 2016 included contracts on the Nifty (India), KOSPI 200 (Korea), BankNifty (India), EuroStoxx50 (Eurex), and the S&P500 (CBOE), while most stock options were traded at Bovespa (Brazil), NASDAQ, and NYSE (top three with 47% of the market in 2016). The most

actively traded currency option contract in 2016 was on the USD/INR exchange rate.

Standardization is an important feature of option contracts on exchanges to secure liquidity. This implies that option contracts are only available for specific amounts of the underlying asset, for specific strike prices, for specific maturities, and for specific exercise rights (American versus European). For instance, the CBOE uses the following standardized features for its option contracts on stocks: the underlying value amounts to 100 shares; the strike price intervals are typically set 2.5 points when the strike price is between 5 and 25 USD, 5 points when the strike price is between 25 and 200 USD, and 10 points when the strike price is over 200 USD; and the expiration date is the third Friday of the expiration month, with contracts available for two near-term months plus two additional months from the January, February, or March quarterly cycles. Finally, the stock options are American option contracts. Table 1 gives an example of option price series for different strike prices and time to maturity of 3 months for an underlying stock with a current price of 22.57 USD.

In the following we show that options can be used both for (speculative) investment transactions and to provide hedging. Options are used as an investment when its holder does not hold the underlying asset and is using the investment in the option to (deliberately) create an open position in which he/she is exposed to risk, i.e., to the price evolutions of the underlying asset, hoping that the price evolves in his/her advantage, leading to a gain; however, prices can also move unfavorably, leading to a realized loss. In this sense, these investments are “speculative.” When, on the contrary, one holds the underlying asset (or will acquire it somewhere in the future, during the

Option, Table 1 Example of option price series (in USD)

Strike prices	Call option premia	Put option premia
17.5	5.30	0.10
20	2.90	0.25
22.5	1.15	1.00
25	0.35	2.60
30	0.05	7.70

lifetime, or at expiration of the option), an option can be used to allow the holder to protect (to hedge) the value of the underlying asset against future adverse price evolutions. In section “Basic Payoff Profiles of Options from an Investment Perspective,” we discuss the basic alternative uses of an option as a speculative investment instrument, showing the different payoff (i.e., the gain/loss) schedules; we also show (in section “Options as a Leveraged Investment”) that such option investments are highly leveraged, i.e., enabling high potential returns (but also high losses) at low investment costs (compared to investment in the underlying asset itself). Section “Using Options for Hedging” then discusses the use of an option from a hedging perspective. In section “Option Combinations and the Put-Call Parity Relationship,” we discuss some more sophisticated option combinations and also point to the theoretical so-called put-call parity relationship. Finally, “Conclusion” section discusses some societal consequences of the introduction and use of options. We will use the example of a stock option and the data of Table 1 throughout the remainder of this contribution.

Basic Payoff Profiles of Options from an Investment Perspective

This section gives an overview of the basic payoff profiles of holding or writing call and put option contracts until expiration date. As such, we assume that the parties do not hold the underlying asset, here the underlying stock, and create a particular position, based on their subjective ideas (or superior information) on the future stock price evolution, hoping to make a profit but at the same time exposing themselves to potential losses in case their subjective ideas or information proves wrong and prices move adversely. We will illustrate the basic payoff profiles using the stock option contract with a strike price of 22.50 USD from Table 1. We provide payoff profiles for the holder of the call option (also referred to as a long call) and the writer of the call option (also referred to as a short call). In a similar vein, we provide

payoff profiles for a long put (holder) and a short put (writer).

Long Call

The holder of a call option has the right to *buy* one share of the underlying at the strike price of 22.50 USD. Depending on the stock price at expiration, he will exercise his option or let it expire. For instance, when the stock price at expiration is equal to 20 USD, the holder will let the option expire because one needs to pay 22.50 USD upon exercising the option (right to buy at 22.50 USD), while one can buy the underlying stock directly at the market at a price of 20 USD. In contrast, when the stock price at expiration amounts to 25 USD, the holder will exercise the option and buy the underlying stock from the writer of the contract at a price of 22.50 USD, while its market price is equal to 25 USD. In this way, the holder realizes a profit of 25 USD minus 22.50 USD or 2.50 USD, ignoring any premium paid to acquire the call option.

The example shows that as long as the stock price at expiration is smaller than the strike price or exercise price, the option is worthless and will not be exercised. Put differently, it will take a floor value of zero. When the stock price is lower than the exercise price, the call option is said to be out-of-the-money. As soon as the stock price at expiration is higher than the strike price, the holder will exercise its right and buy the underlying stock at the strike price. The holder will realize a profit, being the difference between the underlying stock price and the strike price. In this case the call option is said to be in-the-money. When the stock price equals the strike price, the call option is said to be at-the-money. This is reflected in Fig. 1 in the asymmetric payoff profile of the call option. Zero profit for stock prices up to the strike price, a positive profit for stock price beyond the strike price. This is the most powerful characteristic of an option. The holder can cut off losses but keep the upside potential open. This powerful mechanism of being able to limit downside losses does not come for free. In order to acquire the option, the holder typically has to pay a premium. In our example, the premium of the call option is equal to 1.15 USD (see Table 1).

Option, Fig. 1 The asymmetric payoff profile of a long call option without the premium

Option, Fig. 2 The asymmetric payoff profile of a long call option including the premium

This implies that as long as the call option at expiration ends up out-of-the-money (the stock price is smaller than the strike price), the holder will not exercise and loses the premium of 1.15 USD. As soon as the option ends up in-the-money (stock price higher than the strike price), the holder will exercise and earns the difference between the stock price minus the sum of the exercise price and the premium (see Fig. 2).

Short Call

The payoff profile of a short call contract reflects the position of the writer of the call option contract. The short call is the mirror image of the long call and follows the decisions of the holder of the call option contract. As long as the stock price at expiration is lower than the strike price, the holder of the call option will not exercise the option

contract and let it expire. This implies that the writer of the option does not have to do anything and can just keep the premium for giving the holder the right to buy the share at the pre-agreed strike price. For instance, in the above example, at a stock price of 20 USD, the call option expires, and the writer collects the premium of 1.15 USD. As soon as the stock price at expiration is higher than the strike price, the holder of the option will exercise his or her right to buy the underlying share at the pre-agreed strike price from the writer of the contract. For instance, in the example, at a stock price of 25 USD, the holder will exercise the option and will turn to the writer of the contract to buy the underlying share at the strike price of 22.50 USD, while the market price amounts to 25 USD. The writer is obligated to deliver the share to the holder in return for a cash amount of

Option, Fig. 3 The asymmetric payoff profile of a short call option including the premium

22.50 USD. The writer thus incurs a loss of 22.50 USD – 25 USD or – 2.50 USD. As the writer also received the premium of 1.15 USD, the net loss is 2.50 USD minus 1.15 USD or 1.35 USD. Figure 3 shows the asymmetric payoff profile of the writer of the call option contract. As long as the stock price at expiration is smaller than the strike price, the maximum profit for the writer is the premium; as soon as the stock price at expiration is higher than the strike price, the writer incurs losses. Note, however, that there is no limit to these losses: the higher the realized stock price, the higher the loss; as such, unprotected engagement in the writing of options is a very dangerous strategy. Note also that when one compares the payoff profiles of the holder (Fig. 2) and the writer (Fig. 3) of the call option, it is clear that their payoffs are mirror images of each other.

Long Put

The holder of a put option has the right to *sell* one share of the underlying stock at the strike price of 22.50 USD. Depending on the stock price at expiration, he will exercise his option or let it expire. For instance, when the stock price at expiration is equal to 25 USD, the holder of the put option will let the option expire because one receives 22.50 USD upon exercising the option (right to sell at 22.50 USD), while one can sell the underlying stock directly at the market at a price of 25 USD. The put option is said to be out-of-the-money. In contrast, when the stock price at expiration amounts to 20 USD, the holder will exercise the

put option and sell the underlying stock to the writer of the contract at a price of 22.50 USD, while its market price is equal to 20 USD. The put option is in-the-money. In this way, the holder realizes a profit of 22.50 USD minus 20 USD or 2.50 USD, ignoring any premium paid to acquire the option. If one also takes into account the premium of 1.00 USD (see Table 1), the net profit amounts to 1.50 USD. Figure 4 shows the asymmetric payoff profile of a long put option. As long as the stock price at expiration is higher than the strike price, the put option is out-of-the-money and will not be exercised; hence, the holder just loses the premium. As soon as the stock price at expiration drops below the strike price, the put option ends in-the-money and will be exercised, leading to a positive profit, again largely unlimited (constrained only by the asset becoming completely worthless, in which case the profit here is 21.50 USD).

Short Put

Figure 5 shows the payoff profile of a short put or the position of the writer of a put option contract. The short put is the mirror image of the long put and follows the decisions of the holder of the put option contract. As long as the stock price at expiration is higher than the strike price, the holder of the put option will not exercise the option contract and let it expire. This implies that the writer of the option does not have to do anything and can just keep the premium for giving the holder the right to sell the share at the

Option, Fig. 4 The asymmetric payoff profile of a long put option including the premium

Option, Fig. 5 The asymmetric payoff profile of a short put option including the premium

pre-agreed strike price. As soon as the stock price at expiration is lower than the strike price, the holder of the put option will exercise his or her right to sell the underlying share at the pre-agreed strike price from the writer of the contract. The writer will incur losses in this instance, which become higher at lower prices, and again constrained only by the asset becoming completely worthless, in which case the loss here is 21.50 USD. It reiterates the considerable riskiness involved in option writing.

Options as a Leveraged Investment

It is important to understand that options allow for highly leveraged investments. The cost of investing in an option is much lower than that of investing in the underlying asset: investing in say

buying a long call (at 22.50 USD) costs the holder 1.15 USD (the premium), while buying the stock itself requires an investment of 22.57 USD. The evolution of the payoff of both will depend on the stock price evolution, but the payoff of an option is much more sensitive to these price changes than that of the investment in the stock: assume that, at expiration, the realized stock price equals 25 USD. Then the rate of return of investment in buying the stock is about 10.8% (the difference between current and buy stock price, which is 2.43 USD, divided by the investment cost of 22.57 USD), while the rate of return on the option equals 117% (the payoff at 25 USD from Fig. 2, which is 2.50 USD, divided by the investment cost of 1.15 USD). Of course, at adverse price changes, the negative rate of return incurred on a

stock investment is lower than that on the option, which is often equal, but limited, at losing the full investment cost (when the option expires unexecuted).

Using Options for Hedging

When one holds the underlying asset, an option can be used to allow the holder to protect (to “hedge”) the value of the underlying asset against future adverse price evolutions. In fact, this was the prime reason why options were designed. More particularly, the holder can buy a long put, which is identical to the example of Fig. 4. The final result is given by Fig. 6: it is a combination of the stock price curve, which shows the result of stock price changes when being unprotected, with the long put payoff curve. The combination of the two curves provides for the final “protective put” result. It shows that when the stock price declines, this is largely compensated by the gains that the holder makes in that case on the long put position, while, as the stock price increases, the option expires unexecuted (with a loss equal to the premium). As a result, the use of this long put allows the holder of a stock to lock in a minimal (“floor”) value of the stock of 21.50 USD (which is the exercise price minus the premium of 1 USD), irrespective of what happens to the stock price, while still being able to enjoy the upward potential

in case the stock price increases. It is clear from comparing the (unprotected) stock price and the protective put curves that hedging does not always lead to the best result (the highest stock value); in case of stock prices higher than 21.50 USD, the unhedged position is better than the hedged one (due to the premium paid to buy the long put option), but hedging does avoid large losses in case of a large stock price decline. The protective put is basically an insurance against a crash of the value of the stock (or a portfolio of stocks). The availability of options with different strike prices will allow for fine-tuning of this position, where locking in a somewhat higher minimal value (by using long put options with a higher strike price) will come at the expense of a lower remaining upward potential.

Similarly, when one will acquire the underlying asset somewhere in the future, during the lifetime, or at expiration of the option, an identical strategy of buying a long put can protect against the risk of a drop in the price of that asset in the meantime, leading to the same result as in Fig. 6. If prices turn out lower than the strike price, the holder will exercise the option and sell the share that he/she acquired now at that strike price; as such, a minimal income of 21.50 USD will be secured. At stock prices higher than the strike price, the holder will sell the acquired share in the market at that higher price, and the net income will be that higher price minus the option premium paid.

Option, Fig. 6 The protective put result

Option Combinations and the Put-Call Parity Relationship

Besides the standard payoff profiles of the basic option positions (call/put, long/short), one can create any tailor-made payoff profile by combining several call and put options together, which will accommodate best the particular subjective ideas or information on future price developments, in case of the use of options as an investment vehicle, or the particular desired hedging outcome otherwise. For instance, one could combine a long call and a long put position with the same strike price in one investment portfolio. The combined payoff of holding both option positions simultaneously is referred to as a long straddle position (see Fig. 7). This long straddle will pay off to the holder as long as the stock price at expiration is lower than 20.50 USD or higher than 24.50 USD. If the option ends up at-the-money (at the strike price of 22.50 USD), the holder incurs a maximum loss of 2.15 USD, being the sum of the premium paid for the call option (1.15 USD) and the premium paid for the put option (1.00 USD). This is a valuable trading strategy if one expects the stock price to break out,

Option, Fig. 7 Payoff profile of a long straddle position

but one is uncertain in which direction. For instance, one expects a pharmaceutical firm to announce news on its R&D program: if the news turns out to be good, one expects the stock price to increase; if the news is unfavorable, one expects the stock price to decline. A straddle position could be a valuable trading strategy in such a situation. In contrast, if one expects the stock price not to move, one could create a short straddle by simultaneously writing a call and put option with the same strike price. If the future materializes as expected, the writer will capture both premia; if the price moves too much in either direction, the writer will incur (unlimited) losses.

An alternative strategy to a long straddle is to combine the long call option and the long put option with different strike prices. For instance, one can combine a long put with a strike price of 20 USD with a long call with a strike price of 25 USD. Such a combination is referred to as a long strangle. In comparison to the long straddle, the maximum loss is smaller (0.60 USD versus 2.15 USD), but the underlying stock price has to move more before the holder will profit (20/26 USD versus 20.50/24.50 USD). By setting the strike prices of the call and put options closer or further away from each other, the holder of the strangle can trade-off reducing the maximum loss with a larger break-even point (Fig. 8).

Finally, Fig. 9 shows a combination of option contracts with other financial assets, which will

Option, Fig. 8 Payoff profile of a long strangle position

Option, Fig. 9 Deriving the put-call parity

also lead to the derivation of the so-called put-call parity. The upper panel again shows the combination of a share with a long put contract, which is the same as the protective put situation of section “Using Options for Hedging” (and Fig. 6), without including the premium. The lower panel shows a fiduciary call position. It involves entering into a long call position and simultaneously investing the present value of the strike price on a risk-free interest account. One can observe that the payoff profile of the protective put and the fiduciary call is exactly the same: the value of a share plus a long put equals the payoff of a long call with the present value of the strike price. Or, put differently, the value of a long put equals the value of a long call plus the present value of the strike price minus the value of the underlying share. This relationship is referred to as the put-call parity and expresses the relationship between the value of a call option and an otherwise identical put option. This implies that once one knows

the value of a call option, one can easily calculate the value of a corresponding put option. The put-call parity is a powerful relationship as an arbitrage constraint on option prices and as a tool to transfer risk between options (Haug and Taleb 2011).

Conclusion

The explanation of their dual use in this contribution has shown that the creation of the option instrument and option markets has brought about real benefits to its users and financial markets at large, first of all through the ability of individual investors, financial and nonfinancial firms, as well as governments to hedge themselves against all kind of underlying financial risks, which provide more financial stability and insurance against catastrophic outcomes, and, secondly, through the creation of additional financial, highly leveraged

investment opportunities, which combine flexibility with low investment input and high potential returns. At the same time, as also shown in this contribution, these benefits come at the expense of potential high costs to the same aforementioned types of users, and even at the world systemic level, due to the potential negative externalities caused when options are used in highly speculative investment strategies that go wrong, in the sense that they result in huge, sometimes unlimited, losses, leading to severe financial distress not only in these entities, but which can then potentially also be transmitted throughout interlinked financial markets, firms, countries, and the financial system at large. Well-known examples include the presence of “rogue traders” such as in the case of Barings Bank or the use of options in speculative currency attacks against countries (see, e.g., Jacque 2015). Preventing such potential catastrophes requires the use of appropriate and rigorous checks and balances at the level of individual firms or governments, self-regulation at the level of financial markets, and other regulatory interventions at the global level (Van Liedekerke and Cassimon 2000).

Abstract

Option prices models refer to the overall collection of quantitative techniques to value an option given the dynamics of the underlying asset. Option prices models can be classified into European-style versus American-style models, into closed-form versus numerical expressions and into discrete versus continuous time approaches.

Definition

Quantitative techniques applied to compute the theoretical value/market price of a financial option given the characteristics and properties of the underlying asset. They can be classified into European-style versus American-style models,

closed-form versus numerical expressions, and discrete versus continuous time approaches.

references to option prices models for other underlying assets at the end.

Introduction

Options give the holder the right to buy (in the case of a call option) or sell (in the case of a put option) the underlying asset (e.g., shares, stock indices, currencies) at an agreed price (strike price or exercise price) during a specific period (in the case of American options) or at a pre-determined expiration date (in the case of European options). Holding an option has a particular value, determining the (market) price (the “premium”) at which this option can be bought and sold. While many financial options are actively traded on an exchange and these market prices are easily observable, financial actors also rely on option prices models to calculate the theoretical (market) value of an option. Option prices models refer to the overall collection of quantitative techniques to value an option given the dynamics of the underlying asset. Although a complete taxonomy of option prices models is outside of the confines of this contribution, they can be classified into European-style versus American-style models, into closed-form versus numerical expressions and into discrete versus continuous time approaches. In this contribution we mainly focus on stock options, while we provide

Basic Option Relationships

As an option is a financial instrument which gives the holder the right, but not the obligation, to exercise, the typical payoff structure of an option is asymmetrical. The market value or premium of the option typically consists of the sum of the intrinsic value and the time value. It is indicated by the solid line in Fig. 1. The intrinsic value of an option is its value upon immediate exercise. The dash line in Fig. 1 indicates the intrinsic value and shows the typical hockey stick payoff profile of a call option. When the stock price S is higher than the exercise price X , the call option is said to be in the money as it takes a positive intrinsic value ($S-X$). In case the stock price is lower than the exercise price, the call option will not be exercised as it is cheaper to buy a share directly at the stock market. The call option is said to be out of the money and its value amounts to zero. The call option is said to be at the money when the stock price equals the exercise price. The intrinsic value of the option is its value at expiration date or when it is exercised earlier: the payoff to the holder of the option equals $\max(S-X,0)$. The option’s market price prior to expiration or early exercise is higher than the intrinsic value as one has to add the time value on top of it. The time value reflects the

Option Prices Models,
Fig. 1 Value of a call option as a function of the stock price

flexibility that the holder has in postponing the decision to exercise the option until the expiration date, at the latest. Figure 1 also indicates the upper and lower boundary conditions of the option value. The maximum value of the call option is the underlying stock price S . An option can never be worth more than what it costs to acquire the stock directly. The minimum value of the call option is the intrinsic value, or $\max(S-X, 0)$. Finally, the market value depends on five parameters: the stock price, the exercise price, the time to expiration, the volatility of the stock return, and the risk-free interest rate. With the exception of the exercise price, all parameters have a positive impact on the market value of the option. These are the five value drivers of any option and will be the input parameters of any option prices model. The next section discusses different modeling approaches to calculate the theoretical market price of an option.

European Option Prices Models

European option prices models refer to quantitative techniques used to value options which can only be exercised at their expiration date and where the holder has no decision to make during the lifetime of the option. Such basic plain vanilla options are typically valued using a closed-form expression such as the continuous time Black-Scholes model. When exact formulas are not available, numerical expressions are used to put an approximate value on the option. The discrete time binomial option pricing model is an

example of the latter. Both models have in common that option valuation is based on the idea of a replicating portfolio. By creating a portfolio of stocks and bonds with the same payoff as the option in every state of the world, the law of one price requires the current value of the replicating portfolio to be equal to the current option value. As one can easily observe the market prices of the assets in the replicating portfolio, one can thus also value the option. A detailed analysis of this concept is outside the confines of this contribution.

The Binomial Model

This model assumes the stock price moves in every time period Δt either upward with factor u or downward with factor d . For instance, Fig. 2 illustrates how the stock price can move in a two-period binomial model. The left panel shows how the possible price path of the underlying stock price, while the right panel shows the corresponding option payoff tree. After two time periods there are three possible stock prices at maturity date and three corresponding option prices. As the option is at expiration, its value can easily be computed as it only takes intrinsic value: the stock price at each node minus the exercise price, or zero, the highest of both. With a process called backward induction one moves one step back in the option payoff tree to calculate the option value in earlier tree steps until one reaches the current moment.

To develop a realistic tree of possible future stock prices, one needs to determine the size of one tree step and the upward and downward

Option Prices Models,
Fig. 2 Two-period
binomial trees

jumps of the stock prices. The time interval Δt depends on the lifetime of the option ($T-t$) and the number of tree steps n . The left panel in Fig. 3 illustrates how one can expand the number of possible share prices at expiration by increasing the number of tree steps. For instance, if time to expiration $T-t$ is 1 year and one uses 250 tree steps n , then the stock moves up or down every time interval $\Delta t = \frac{T-t}{n} = \frac{1}{250}$ or approximately one step equals one trading day.

To determine the value of the upward and downward movement the standard binomial option model of Cox et al. (1979) fixes $u = e^{\sigma\sqrt{\Delta t}}$ and $d = 1/u$. Once both parameters are determined, one can develop the binomial tree and calculate the current option value by discounting at each node of the tree the upward and downward expected option values:

$$C = \{[C_u \times p] + [C_d \times (1 - p)]\}e^{-r} \tag{1}$$

where C is the current option price, C_u is the expected option value in the upward world, C_d the expected option value in the downward world, p the risk-neutral probability that the stock moves upward with $p = \frac{e^r - d}{u - d}$, and r the risk-free interest rate.

The right panel in Fig. 3 shows that increasing the number of tree steps to infinity produces a lognormal distribution of possible share prices at expiration. In that case, the binomial model converges to the continuous time model we discuss in the next section. In practice the binomial model produces a good approximation of the Black-Scholes model from 250 tree steps onwards (see Fig. 4).

The Black-Scholes Model

Probably the best known model has been developed by Black and Scholes (1973). Its popularity is derived from its closed-form solution and fast

Option Prices Models, Fig. 3 Possible price paths and distribution of stock prices at expiration

Option Prices Models, Fig. 4 Convergence of the binomial model towards the Black-Scholes (BS) model

and relatively simple computation. Its main disadvantage is due to the strict assumptions underlying the model (Hull 2011): (i) frictionless markets, implying no transaction costs or taxes, nor restrictions on short sales; (ii) continuous trading is possible; (iii) the risk-free (short term) interest rate is constant over the life of the option; (iv) the market is arbitrage-free; and (v) the time process of the underlying asset price is stochastic and exhibits a process assuming asset prices to be lognormally distributed and returns to be normally distributed. Obviously, any violation of some of these assumptions may result in a theoretical Black-Scholes option value which deviates from the price observed at the market. The option value C according to the Black-Scholes model can be calculated as:

$$C = S N(d_1) - X e^{-r_c(T-t)} N(d_2) \quad (2)$$

$$d_1 = \frac{\ln\left(\frac{S}{X}\right) + \left(r_c + \frac{1}{2}\sigma^2\right)(T-t)}{\sigma\sqrt{T-t}} \quad (3)$$

$$d_2 = \frac{\ln\left(\frac{S}{X}\right) + \left(r_c - \frac{1}{2}\sigma^2\right)(T-t)}{\sigma\sqrt{T-t}} \\ = d_1 - \sigma\sqrt{T-t}, \quad (4)$$

where S is the current stock price, X the exercise price, $T-t$ the time to expiration (in years), σ the annualized standard deviation of the stock return, r_c the continuous risk-free interest rate, and $N(d)$ the cumulative normal probability density function.

American Option Prices Models

American option prices models refer to quantitative techniques used to value options which can be exercised earlier than the expiration date or where the holder has to make other decisions during the lifetime of the option. The main difference between European and American option models is thus the incorporation of the early exercise feature. American call options on nondividend

paying stocks are equal in value than an otherwise identical European call option. Early exercise of an American call options on a nondividend paying stock would render the holder the intrinsic option value but would lose the time value of the option. Put differently, the American call option on a nondividend paying stock is worth more alive than dead. Therefore, one can value an American call option on a nondividend paying stock with European option models. The story changes when the stock distributes one or more dividends during the lifetime of the option. In that case, early exercise of American call options on stocks is a valuable alternative and depends on the tradeoff between losing the time value of the call option and capturing the dividend(s). A closed-form solution for the valuation of an American call option with one single dividend payment is offered by Geske (1979a), Roll (1977) and Whaley (1981), while Cassimon et al. (2007) offer a similar solution for the case of multiple dividends. A popular approximation is offered by Black (1975). Other valuation models for American options include trinomial models (Kamrad and Ritchken 1991), finite difference models (Brennan and Schwartz 1977, 1978), Monte Carlo simulations (Broadie and Glasserman 1997; Longstaff and Schwartz 2001; Moreno and Navas 2003), and quadratic approximations (MacMillan 1986; Barone-Adesi and Whaley 1987). A detailed discussion of these models is beyond the confines of this contribution, but we refer the reader to the references for further details.

Other Option Prices Models

Often more complicated option models are needed to handle the specific nature of the option features or the dynamics of the underlying asset. Such models include jump models (Merton 1976), compound option models (Geske 1979b; Cassimon et al. 2004), or barrier models (Li et al. 2013).

In the option literature one can also find option models for other financial assets, such as options on currency (Garman and Kohlhagen 1983; Amin and Jarrow 1991), options on futures (Black 1976;

Ramaswamy and Sundaresan 1985), options on commodities (Hilliard and Reis 1998), options on (stock) indices (Merton 1973; Chance 1986), swaptions (Black 1976), options on interest rates (Ho and Lee 1986), and bond options (Schaefer and Schwartz 1987). Option models are also used in handling credit default risk (Merton 1974; Crosbie and Bohn 2003).

Ordoliberalism

Stefan Kolev

Wilhelm Röpke Institute, Erfurt and University of Applied Sciences Zwickau, Zwickau, Germany

Abstract

The purpose of this entry is to delineate the political economy of a group of authors related to ordoliberalism, the German variety of neo-liberalism. To reach this goal, a history of

economics approach is harnessed. First, the historical background around the time of its inception is presented. Second, an overview of the substantive core and of the heterogeneity across the different strands of ordoliberalism is reconstructed. Third, its historical impact on and current potential for political economy are evaluated. While this entry focuses on the general patterns of ordoliberal political economy, separate entries delineate the specificities in the research programs of Walter Eucken, Wilhelm Röpke, and Franz Böhm.

Introduction

A multifaceted group of scholars with a research program at the intersection of political economy, law, and social philosophy has become famous since 1950 under the name of “ordoliberalism” (Moeller 1950). The intellectual history of this group has received much attention, as ordoliberalism has ever since unfolded a seminal impact in Germany, Central Europe, and beyond. This entry has a threefold purpose: first to delineate the history of ordoliberal thought, second to present the overarching research agenda of the ordoliberals, and third to assess its impact and potential for today. Given the heterogeneity and the implicit division of labor within the group, this overview is complementary to the entries on Walter Eucken, Franz Böhm, and Wilhelm Röpke which present the specificities as detailed in the respective primary literature.

“Ordoliberalism” is sometimes used synonymously with the term “Freiburg School,” which is imprecise. While the Freiburg School around Walter Eucken (1891–1950) and Franz Böhm (1895–1977) constitutes the core of ordoliberal group, also authors who strictly speaking do not belong to the Freiburg School have been perceived as representatives of ordoliberal thought. Among them, the most prominent are Wilhelm Röpke (1899–1966), Alexander Rüstow (1885–1963), and Alfred Müller-Armack (1901–1978), but also F.A. Hayek (1899–1992) at certain stages in his evolution can be seen as contributing to the ordoliberal research program

(Oliver 1960, pp. 118–119). Despite all cultural and biographical differences, it is important to note that these thinkers broadly belong to the same generation and also share a common goal in the 1930s and 1940s: to revitalize liberalism whose standing and relevance at that point are at an all-time low. For understanding the inception of ordoliberalism and its particular substantive core, a twofold perspective is necessary: one which sheds light on the specificities of German economics in the 1930s and another which embeds the group in the general movement of international scholarship, self-depicting itself around 1938 as “neoliberalism.”

Formative Years

German economics was in a deplorable state in the early 1930s. The academic landscape was largely characterized by the ruins of the Younger and the Youngest Historical Schools (Rieter 2002, pp. 154–162; Goldschmidt 2013, pp. 127–129). The tragedy of the discipline became most evident in its lacking capability to provide solutions to the extremely pressing problems of economic life, the hyperinflation in the early 1920s as well as the Great Depression in the early 1930s. Instead, many German economists still fought methodological battles or collected empirical evidence, often lacking the theoretical underpinnings for such inquiries. Dissidents to this development constituted in the 1920s the group of the so-called Ricardians, a collection of younger scholars who intended to re-link the discipline back to modes of systematic theorizing – with Rüstow, Eucken, and Röpke among the most active members of the group (Janssen 2009, pp. 34–48; Köster 2011, pp. 224–228). Even though the annus horribilis of 1933 physically separated them – with Rüstow and Röpke leaving as exiles to Turkey and Eucken staying as a “half-exile” (Johnson 1989, p. 57) in Germany – the intellectual ties remained and even solidified over the decades to follow. In the immediate aftermath of 1933, Eucken formed a scholarly community at Freiburg with Franz Böhm and another law professor, Hans Großmann-Doerth (1894–1944),

which became the core of what would later be called the Freiburg School of Ordoliberalism or the Freiburg School of Law and Economics (Vanberg 1998, 2001). In 1936, the three published a manifesto under the title “Our Mission” (Böhm et al. 2008). Eucken and Böhm opposed National Socialism in manifold academic contexts, among others vis-à-vis the 1933–1934 rectorate of Martin Heidegger as well as in diverse intellectual resistance groups preparing for the age after National Socialism, later to be called the Freiburg Circles (Rieter and Schmolz 1993, pp. 95–103; Nicholls 1994, pp. 60–69).

The overarching goal of the Freiburg School and its 1948-founded publication organ, the “ORDO Yearbook of Economic and Social Order,” is the search for an order which entails a minimum of power, considering all forms of power relations – stemming from the state, from the market, and from other social orders (Sally 1998, pp. 110–117; Foucault 2008, pp. 129–158). The seminal analytical distinction of the Freiburg School is between “order” and “process”: while the level of economic order is one of the “rules of the game,” the level of economic process is one of the “moves of the game” (Wohlgemuth 2013, pp. 157–159). Building upon this distinction, the Freiburg School conceived a term which until today is considered by many its trademark – “Ordnungspolitik.” Based on his theory of orders and the above distinction, Eucken formulated the task for the power-fighting state: to set the “rules of the game” by “Ordnungspolitik” (translatable as “order-based policy” or, more broadly, as “rule-based policy”) for enabling Eucken’s normative vision of the “competitive order” but to abstain from intervening in the “moves of the game” which are the protected domain of the private individuals with their interactions. With this, Eucken aimed to draw the border to interventionism which disregards such constraints and arbitrarily intervenes in the “moves of the game” of the economic process for improving the performance of the economy – instead, his theory and his perspective on economic policy are very much in line with the “problem of constitutional choice, i.e., as a question of how desirable economic order can be

generated by creating an appropriate economic constitution” (Vanberg 2001, p. 40).

Complementary to this agenda at Freiburg, the exiles Röpke and Rüstow developed a strand in ordoliberalism which would later be called “sociological liberalism” (Renner 2002, p. 61). Their inquiry was focused on the question how social stability and cohesion are possible amid the challenges of “enmassment” of modern society with its uprooting of the individuals from their traditionally cohesive small groups (Friedrich 1955, pp. 512–525; Kolev 2015, pp. 426–427). Just as Eucken and his associates, Röpke and Rüstow understood the economy and its framework as being embedded into the other social orders, but unlike Eucken they saw the task of economists to also look beyond the context of the economic order and to explicitly theorize its interrelationship to the other social orders, as the potential sources of instability within such an interdependent system of social orders can lie well beyond the economic order (Zweynert 2013, pp. 116–120). The task for a political economist is also to be aware of one basic property of the economic order: that it tends to use up its own stability resource, so that these resources and pillars (called by Röpke “anthropological and sociological” prerequisites) have to be permanently checked and, if necessary, stabilized anew by the state and other players in civil society (Kolev 2013, pp. 133–136).

Impact in Later Decades and Relevance for Today

The quests of the ordoliberal exiles and “half-exiles” are also to be contextualized within the broader intellectual perspective of Europe and the United States at their time. Freiburg was not completely isolated – Röpke, Rüstow, and Hayek stayed in touch with Eucken, in Röpke’s case even well into the year 1943. Even though Eucken did not attend the Colloque Walter Lippmann in 1938, Röpke and Rüstow were among its most active participants, proposed the term “neoliberalism” for the movement of revitalizing liberalism, and also had severe debates on what neoliberalism

should mean along the maxims of ordoliberal political economy, in particular with Ludwig von Mises (Gregg 2010, pp. 82–86; Burgin 2012, pp. 67–78; Kolev 2016, pp. 14–17). Hayek’s evolution is of special interest here, as in the late 1930s and in the 1940s, his incipient political economy, including “The Road to Serfdom,” displayed strong similarities to the ordoliberal research program (Streit and Wohlgemuth 2000; Kolev 2010, 2015, pp. 432–436). Interestingly, a research program with yet again strong similarities to the one in Freiburg came up in Chicago of the time (Van Horn 2009; Köhler and Kolev 2013), later to be called by James M. Buchanan the “Old Chicago” School (Buchanan 2012), and it was Hayek who let Freiburg and “Old Chicago” meet in the session on the potential of the competitive order to become an alternative to *laissez-faire* at the very first meeting of the Mont Pèlerin Society in 1947 (Kolev et al. 2014, pp. 15–20).

The influences to and from ordoliberalism are not confined to the realm of academic economics. All ordoliberals named above were not of the ivory-tower scholar type – their political economies explicitly aimed at becoming tools for practical economic policy. The ways for channeling their theories into practical economic policy were different: Müller-Armack’s 1946-coined term of the Social Market Economy became a successful device for introducing the market economy to capitalism-skeptical German postwar society (Dornbusch 1993, pp. 881–883; Watrin 2000) but has later been used in countries as diverse as Chile, Belarus, or the European Union to frame the economic policy agenda of different administrations. Eucken’s “Ordnungspolitik” is until today a powerful rhetorical tool in Germany to introduce market-oriented reforms or to block interventionist policy proposals as being “Ordnungspolitik”-incompatible. Röpke’s countless appearances in Swiss, German, and international media made him the most active public intellectual of all ordoliberals and until today he is an authority in economic policy matters quoted especially often in Switzerland. Böhm made a longer digression into the realm of parliamentary politics and, after several years of intense debates especially with the Federation of German Industry, was a principal

figure in introducing the “Act against Restraints of Competition” (GWB) in 1958, later to become a leading norm for the formulation of antitrust law in the European Union (Giocoli 2009). Until today, also macroeconomic issues like the optimal monetary policy of the European Central Bank or the fiscal policy debt-brake legislation in European Union countries have been discussed with reference to the rule-based approach of “Ordnungspolitik” (Dullien and Guérot 2012; Kundnani 2012; Wren-Lewis 2012; Feld et al. 2015; Bofinger 2016).

In addition, there have been attempts not only to perceive ordoliberalism as a history of economics artifact or as a guiding tool for practical economic policy, but also to connect it to new rule-based approaches in institutional and constitutional economics (Vanberg 1988; Ebeling 2003; Leipold and Wentzel 2005; Boettke 2012; Zweynert et al. 2016). Considering the multiple economic crises of our time but also the multiple crises of today’s economics as an allegedly useless academic discipline in the eyes of the general public and of many politicians, students, and neighboring social sciences, ordoliberalism’s rich heritage can be one of the sources necessary to revitalize the discipline and to regain the confidence of its currently dissatisfied “customers.”

Organization

Mehmet Bac

Sabancı University, Istanbul, Turkey

Abstract

Organizations exist because they cost-effectively coordinate and provide incentives relative to alternative modes of transacting. The article exposes some of the main economic explanations for why organization emerges, what it does and how its scale and scope are determined, highlighting the role of a hierarchical command structure in aligning the members’ objectives with those of the organization and successfully overcoming problems of asymmetric information and collusion.

Synonyms

Firm; Government; Institution

Definition

Organization is an entity designed to influence behavior and reach collective objectives for its members.

Numerous classifications of organization can be made to emphasize its different functions or characteristics, according to objectives, output type, ownership structure, hierarchical network, degree of delegation of decisions and divisionalization, financial structure, reliance on technology and innovation, measurability of outputs and inputs, power of incentives, size in labor force, output or asset value, and scope measured vertically or horizontally in terms of diversification of output and tasks. In the modern state, almost all economic and social activities involve some form of integration and organization. The *raison d’être* of organization is cost-effective coordination and provision of incentives in transactions where private negotiations by independent units fail to generate satisfactory outcomes.

The new institutional approach to organization of activity, common in economics and legal studies, puts the *transaction* to the forefront as the unit of analysis. The key to understanding the organization and its boundaries is thus the nature of transaction costs, viewing the organization as a solution by the actors to executing transactions at minimal cost (Coase 1937).

The informational requirements for value-maximizing coordination of a wide range of activities are huge, by far exceeding the signals contained in market prices. The organization coordinates along multiple dimensions. It allocates productive and consumptive resources across tasks and members. It coordinates over time as well: to “fit the pieces” properly, avoid effort duplication, and produce value in rather unpredictable environments, the organization solves assignment and synchronization problems. It induces mutual adjustments and achieves standardization in processes, outputs, knowledge, and even norms and values. By creating a moral order and identity in the minds of its members, the organization copes better with the rise in communication and coordination costs that follow specialization of its labor motivated by productivity.

Transaction costs have two main sources. The first, *bounded rationality*, is the limited capacity of humans to foresee the relevant contingencies and describe with precision those foreseen, including the corresponding set of actions that should be taken in each contingency. Bounded rationality implies that the parties to a transaction will draft an incomplete contract, with gaps and missing provisions. Incompleteness is manifest in the contractual terms of idiosyncratic transactions in which parameters such as “quality” and “know-how” are important, yet difficult to define unambiguously. The resulting cost for the parties can be huge because contract incompleteness invites opportunistic behavior. Organization may cope better with contract incompleteness because it replaces the costly renegotiations in unforeseen contingencies by a command structure where people are told what to do. Integration of a transaction is supplemented by implementing an appropriate incentive scheme, instituting a monitoring and command system, and bringing to the forefront career concerns of the parties, inside and outside the organization.

The second source of transaction costs is information problems. Members at all levels of the organization have private information, but their goals are not necessarily congruent with those of the organization. The simplest nonmarket paradigm to study the information problems and their incentive implications is the principal-agent framework. In its canonical form, the principal makes a take-it-or-leave-it contract offer to the agent who, if the parties agree, performs a task which the principal cannot for lack of time or expertise. The principal faces three types of informational obstacles in motivating the agent to take the appropriate action: *hidden action* (moral hazard), which refers to unobservability of the agent’s actions; *hidden knowledge* (adverse selection), which refers to the agent’s task-relevant private information; and *verifiability* of relevant parameters and contract terms by third parties, such as a court of law.

The challenge in controlling the hidden action problem is instituting objective and verifiable performance measures that are somehow correlated with the agent’s unobservable actions, then, using

these measures to tailor an incentive package which indirectly and cost-effectively aligns the agent’s goals with those of the principal. However, because the relation between the agent’s actions and performance measures is typically non-deterministic, raising the power of incentives inevitably exposes the agent to risk. This generates a utility loss which the principal bears in the form of a “risk premium” if the agent is risk averse. The solution to the hidden action problem thus poses a dilemma for the organization, namely, the need to balance incentive provision costs against the costs of risk bearing (Grossman and Hart 1983). In practice, firms may choose to offer stock options to their CEOs to motivate them so that they in turn motivate the employees, but the considerable indeterminacy in stock prices coupled with the obstacles in measuring performance typically reduces the efficacy of such performance-based payment schemes (Chiappori and Salanié 2003). These negative consequences amplify in complex and bureaucratized, multi-layer organizations (Williamson 1985). Smaller, owner-controlled business organizations have an advantage in coping with incentive problems that are rooted in unobservability of its members’ actions.

The second informational obstacle, hidden knowledge, usually takes the form of private information about individual characteristics, some task specific and others general, such as effort cost or endurance, creativity, and productivity in teams. These are crucial pieces of information for efficient matching of tasks with employees, physical with human resources. Screening methods before and during employment such as interviews, contract design, and probation terms can be used to extract information from the agents, yet in practice the power of these instruments is limited and agents enjoy information rents. To protect their rents, low-cost agents have no incentive to reveal their productivity if the principal is not able to commit to not using the information to the detriment of the agent. The expectation that revelation of productivity will raise future performance standards is known as the ratchet effect (Freixas et al. 1985).

The inability to measure and verify relevant performance parameters such as quality, effort, output, and payments is the third informational obstacle to motivation. The distinction between observability and verifiability is important here. The scope for opportunistic behavior remains strong even if the parties can perfectly observe the relevant parameters, provided courts are not able to verify them. The theory of repeated games suggests that third-party verification is not an issue because cooperative behavior can be sustained as a (subgame-perfect) Nash equilibrium as long as the parties perfectly observe the outcome, but this conclusion collapses when the parties heavily discount future payoffs or if the frequency of transaction is not sufficiently high.

The information problems and their inefficiency consequences amplify in teams, where two or more agents are expected to contribute to a set of common objectives. Each agent has an incentive to free ride, withhold effort, and rely on others. Peer monitoring and pressure are often not strong enough to fully overcome this problem. Restoring optimal incentives in a team context can be very costly too, as the principal may have to pay huge individual rewards for a successful team outcome to fully eliminate the possibility of free riding. Handling these costs leads to differences in the organization's size, incentive structure, and architecture.

Organization outperforms alternative modes of governance for idiosyncratic transactions that are projected to occur frequently, based on specialized needs (Williamson 1985). Task specialization and relationship-specific investments on assets and knowledge generate dependencies. Because these investments are worth more for the transacting parties in their relation than outside, ideally the relationship should be governed by long-term contracts that fully protect relationship-specific investments. But contracts are incomplete and open to opportunism, which suggests the best environment to protect relationship-specific investments is the vertically integrated command structure of the organization (Grossman and Hart 1986).

The organization can be viewed as a nexus of incomplete contracts between principals and

agents in a cascade of relationships (Alchian and Demsetz 1972). The interactions are reflected in a formal architecture, usually a hierarchical structure that shows the degree of centralization, how the constituent units are arranged, authority allocated, and tasks assigned. The channels of this architecture produce decisions, performance supervision at multiple levels, and manage information flows. Aspects of information processing include data generation and establishing a network through which information, processed or raw, is transmitted with maximal processing capability and minimal delay. The lesser the informational disadvantage of a unified governance and the greater the need for coordination, the greater the advantage of organization relative to its alternatives. The organization also has an advantage in performing pressing tasks with minimal delay (Bolton and Farrell 1990).

An organization is informationally efficient if its network minimizes the need for extra information in checking whether a new project or plan of action is worthwhile. Though a reversed tree form of hierarchy can minimize processing delays, usually this is not a fully symmetric, balanced hierarchy. Rather, it is optimal to involve decision nodes at upper levels of the hierarchy in various stages of the data processing exercise (Radner 1992). Placing a group of equally effective people in parallel as a polyarchy ends up selecting a larger number of available projects than a linear hierarchy order where final approval requires sequential approval by all. Therefore, the incidence of type-I statistical error is higher in hierarchy, whereas polyarchy displays higher errors of type II. The relative performance of the two modes, polyarchy or hierarchy, depends on the importance of the two error types (Sah and Stiglitz 1986). Because projects or new ideas vary in this respect, the organization's flexibility to form polyarchic or hierarchic screens in decision-making is an asset. Organizational form also matters, in particular, regarding coordination of changes and the scale of experimentation with new projects. The M-form has an advantage in coordinating attribute matching and flexibility in choosing the scale of experimentation, whereas the

U-form organization achieves better coordination in attribute compatibility (Qian et al. 2006).

Although the formal chart may look hierarchical, many activities and interactions within the organization do not necessarily follow hierarchy. Delegation and decentralization is the norm. The level of decentralization is often defined in terms of the span of control. So, of two organizations with six people, the one in which five specialists support a middle-level manager is more centralized than one in which two pairs of specialists support two middle-level managers. But the real allocation of authority may be quite different, as the organization may selectively and informally authorize the subordinates while formally assigning authority to an overloaded superior. This structure is shown to serve indirectly the motivation of subordinates who know that their ideas and preferences will sometimes be implemented (Aghion and Tirole 1997). The optimal overlap between real and formal authority balances these motivational benefits against the risks resulting from dissipation of control, a trade-off that depends on the degree of congruence between the goals of people working at different formal levels of the hierarchy.

Large organizations in particular are vulnerable to *influence activities*. Members spend time and resources to affect the decisions made at upper levels, typically in the form of producing and manipulating evidence to develop credentials for promotion. The resulting loss in the organization's output is termed influence costs (Milgrom and Roberts 1988). In response, the organization should seek an optimal balance between incentives in promotion and incentives in actual positions, as well as credibly modifying the criteria to reduce the attractiveness of positions awaiting promotion. Though improved transparency by adopting clearer rules and criteria is generally considered an organizational asset, it also reduces the cost of identifying whom to influence. If the latter effect dominates, marginal improvements in transparency may well lead to an increase in influence activities (Bac 2001).

Public organizations, including government and most nonprofits, differ from profit-seeking organizations in both fundamental and qualitative

respects. The differences are reflected in their incentive structures and hierarchy. It is generally observed that members of organizations with social or political missions face weaker direct incentives than the employees of a firm. This is partly explained by the higher degree of congruence in the goals of the social or political organization and its members, which reduces the need for powerful incentives. However, the prime explanation is in the feasibility of direct incentive schemes. Public organizations pursue multiple goals which typically are hard to measure and even define. Some of their outputs and services are laden with amenity potential, contributing directly to the owners' and top managers' utility (Demsetz and Lehn 1985). Multitask models of hidden action have shown that when some goals are measurable and others not, an incentive scheme based on the measurable goals distorts actions to the detriment of the non-measurable goals and, hence, may well worsen the overall performance (Holmstrom and Milgrom 1991). If it does, the organization should reduce the power of direct incentives and possibly rely more on alternative instruments of motivation such as monitoring and emphasizing promotion and career concerns (Holmstrom 1999). A more radical response is to create independent units with clear and distinct goals or, if possible, isolate and confine the measurable goals to new specific divisions where high-powered incentive schemes become feasible and effective. Indeed, units and agencies of government are often characterized by independent missions (Wilson 1989; Tirole 1994). Multi-divisional frameworks may generate a loss of coherence in the overall decision-making process, but the benefits from subjecting the units to different masters under tight systems of checks and balances along financial, operational, and implementation dimensions can be notable. In essence, if incentivized to properly defend the cases for alternative causes, competition among advocates of specific goals and interests in the organization may give rise to good policy setting, similar in function to the adversarial adjudication system in courts of law.

Another threat against which all organizations must carefully safeguard is the possibility of

collusion, a formation of an informal coalition to promote the common interests of its members (Tirole 1986). These organizations inside the organization are products of the information problems, combination of hidden action, hidden knowledge, and non-verifiability. Internal collusion comprises members only, whereas external collusion, named “capture” in the regulation context, involves outsiders as well. A supervisor who conceals an employee’s corruption for a benefit in return is internally colluding. Favoritism in transactions with outsiders and the capture of a procurement officer’s or an environmental agency’s decision by a private firm are incidences of external collusion. Internal and external collusion can coexist, as in the case of a coalition of officials which organizes the collection and sharing of corrupt proceeds from the public. Collusion can be temporary, a spontaneous deal *ex post* at the occasion, or it can take a sustained form whereby the parties involved coordinate *ex ante* their actions toward the common collusive objective (Bac 1996).

Sustaining collusion is subject to the same qualitative problems the organization faces in sustaining itself. But the threat of collusion imposes new constraints on incentive schemes, the rule-discretion balance, and the span of control. Stricter decision rules reduce the need to rely on the private information of members, thereby, the stakes of outsiders whom they are transacting with. The cost of a shift to rules is the foregone benefit from occasional and selective use of discretion. The rule to auction all contracts, for example, works extremely well on the price dimension and minimizes the likelihood of capture at the cost of other contract dimensions such as quality, speed, reliability, and reputation of the contractor, which typically are non-measurable but observable by an expert, manager, or official. Alternative instruments to reduce the payoffs to collusion include raising the rewards to supervision and evidence of good performance, introducing rotation, and intensifying monitoring. The cures carry along their risks: monitors are subject to the same threat of collusion, unless replaced by incorruptible electronic accountability systems or cameras. Large rewards to human monitors can prevent collusion

but are obviously costly and risk inducing extortion with fabricated evidence of wrongdoing. As for rotation policies, they prevent development of trust-based relations that help in sustaining collusive behavior, but trust is also an input for cooperation and productivity in teamwork.

Governance of internal and external transactions and acts is subject to labor, administrative, tort, and criminal laws. Internal administrative procedures are activated upon reports of embezzlement and misdemeanor such as harassment, rules on hiring and firing decisions as well as ensuring job safety standards are imposed by labor laws, and strict (vicarious) liability is instituted for torts and crimes committed by employees. Just as the internal rules of the organization serve to align the objectives of its members with those of the organization, these laws can be viewed as a response to the dissonance between the goals of the organization and the society. So, by holding firms strictly liable for the actions of their employees rather than imposing individual liability, the state *de facto* delegates monitoring and partially also enforcement of offenses to the firms. Because the firm is in close relation to its employees and better informed about its environment, it can, less expensively than the state, monitor, prevent, and sanction. The firm is then expected to align incentives and partially shift the liability to its employees, passing the sanctions along to those in violation of the law using its own instruments such as wage policy, firing, and other measures. The lower the ability of the employees to pay for the social damage of their acts and the more effective the firm is in sharing its liability with its employees, the stronger the case for strict liability laws (Posner 1999).

The dominant new institutional economic model of the large corporate organization views shareholders as principals and the board of directors as their agents who monitor the managers on behalf of the shareholders. As an intermediate layer between shareholders and managers, the board is not immune to collusion with management against the shareholders. The risk of collusion is in part remedied by the market for corporate control, in part by equity holdings of the directors. This model is criticized for

neglecting the fact that organization is a distinct legal entity with rights on its own, protected by the state. It is challenged by new theories proposed to understand corporate governance with directors as the principals and the firm as a productive team where relationship-specific investments are emphasized (Blair and Stout 1999). From a legal point of view, shareholders' primacy is questionable, and ownership of the shares does not entail ownership of the corporation, which is an autonomous legal entity. The board of directors is entrusted to act on behalf of and for the benefit of the shareholders, with a fiduciary duty to review the decisions and ensure that they serve the corporation's interests, and a legal right to control the managers' decisions. Directors are motivated not only by their extrinsic compensation package but reputational concerns as well. They act as a mediating principal balancing the competing interests of the team, which justifies their highly independent legal status to carry out this role effectively.

Theories of organization lack a unified approach in explaining the emergence and function of organization as well as its internal practices comparatively, in contrast with a comprehensive set of alternative modes of transacting. A key feature of these alternatives is that they, too, are "organized" to some extent. Markets and the spectrum of hybrid contractual arrangements such as alliances, partnerships, networks, franchising, and subcontracting practices are not spontaneous, improvised systems. They combine aspects of impersonal exchange and formal organizations, just as organizations combine internal markets, decentralization, and command. But the most important obstacle to the research program on a unified theory of organization is the lack of consensus on modeling-bounded rationality of actors whose decisions and choices shape the form and function of the organization.

Abstract

Companies are acknowledged to be distinct legal persons that bear liability both for organizational failures and misconduct of their agents. Civil liability has long been imposed on companies and organizations. Corporate criminal liability has rapidly been expanded in recent years. Following the common law jurisdictions, in which notions of corporate criminal liability were introduced already in the early twentieth century, many civil law countries also recognize the possibility of holding companies criminally liable. However, distinctions in the use and theoretical underpinning of organizational liability remain across countries.

Synonyms

[Company liability](#); [Corporate liability](#)

Corporate Liability Around the World

Laws that render corporations liable have been strengthened after several high-profile corporate scandals, such as accounting crimes and financial fraud scandals (*Enron*, *WorldCom*, *Tyco*, *Parmalat*), the bribery of foreign officials (*Siemens*, *Samsung*), and gross negligence that caused the explosion of the oil rig (*British Petroleum*). Corporations can be held liable for wrongdoings, being subject to civil sanctions and criminal charges. Corporate criminal liability is currently applied in all common law countries

(inter alia, the USA, the UK, Ireland, Canada, and Australia) and in many civil law countries, including the Member States of the European Union; China; some Middle East countries, including Jordan, Syria, and Lebanon; and some post-Soviet countries, such as Baltic states, Moldova, Ukraine, Georgia, and Kazakhstan).

Common Law Countries

The USA

Until the early 1900s, corporations could not be held criminally liable for mens rea crimes. To constitute a mens rea crime, a guilty act (*actus reus*) has to be accompanied by a guilty state of mind or mens rea (Fischel and Sykes 1996, p. 320). Since corporations lack souls that are able to form a culpable intent and bodies to be punished, criminal liability was not imposed on corporations initially (Coffee 1981). But it has long become a common practice to attribute individuals' intents to corporations and make corporations criminally liable (Laufer 2006; Khanna 1996; Stessens 1994). Corporate liability is theoretically based on the legal fiction that corporations are persons distinct from their shareholders, directors, and employees (DiMento and Geis 2005, p. 160; Laufer 2006). Corporations can incur liability based on different grounds.

Vicarious Liability

The common law doctrine of respondeat superior, initially originated in tort law, forms a basis for vicarious liability, which implies that companies are strictly liable for the negligent actions of their agents acting within the scope of employment or authority and with intent to benefit the corporation (Wilkinson 2003; Laufer 1999).

From the perspective of deterrence, vicarious liability is expected to be most effective when a company can successfully monitor and control its agents (Sykes 2012, p. 2164). One of the reasons that justifies vicarious liability is that it mitigates the judgment proof problem. This problem implies that individual defenders have limited wealth and therefore may be unable to fully compensate damages. Compared to individuals,

companies possess larger assets (“deep pockets”) which can be used for paying sanctions and plaintiff compensation. Another justification of vicarious liability is that it prevents companies from inefficient excessive expansion of their activities (Sykes 1984, p. 1246).

Vicarious liability is applied, among others, in the Foreign Corrupt Practices Act (FCPA), enacted in 1977, and in the Alien Tort Statute (ATS), enacted in 1789. These acts are applicable to both domestic and foreign corporations.

Enterprise Liability

According to the theory of enterprise liability, advanced by *Fleming James* and *Friedrich Kessler* in the 1940–1950s, companies should internalize the costs associated with their activities, including the direct and indirect costs of injuries from corporate activities (Witt 2003, p. 39; Keating 2001). Enterprise liability is justified by the presumption that companies are in the best position to control safety and that they can best spread (financially diversify) the costs of injuries caused by defective products or services (Witt 2003, pp. 2, 39; Priest 1985, p. 492). Enterprise liability (firm-level liability) is widely applied in product liability and in ultrahazardous industries.

Compliance-Based Approach

Organizational criminal liability can be imposed based on the duty-based rules (fault-based or negligence rules). The duty-based liability rules foresee a mitigation of liability if corporate compliance programs, aimed at the prevention of wrongdoing, have properly been adopted (Arlen and Kraakman 1997). According to the law and economics literature, negligence liability is generally less efficient than strict liability because under the former tortfeasors do not fully internalize the harm inflicted by wrongdoings. This leads to a too high activity level of tortfeasors, which results in too many wrongdoings (Shavell 1980; Fischel and Sykes 1996, p. 328). The elements of duty-based liability are, however, increasingly applied by means of the compliance-based approach (Moot 2008). For example, the Federal Sentencing Guidelines take into account

corporate compliance programs in imposing liability on companies (Krawiec 2005). The promulgation of the compliance-based approach denotes a shift from respondeat superior liability to duty-based liability of corporate entities (Laufer 1999; Krawiec 2005). The enforcement of effective corporate compliance programs aims at the early prevention of misconduct in organizations, higher compliance efforts, and the creation of a positive law-abiding corporate ethos.

Long before the adoption of the guidelines, corporate compliance programs have been essential in the enforcement of antitrust law, securities law, and environmental law. Ethics codes and voluntary reporting of corporate misconduct, as part of compliance efforts, have also been promoted in the organizations of the defense industry (Walsh and Prych 1995).

The UK

Two high-profile statutes are specifically related to corporate liability in the UK – the Corporate Manslaughter and Corporate Homicide Act of 2007 (CMCH Act) and the Bribery Act of 2010. The Bribery Act foresees corporate liability for bribery. It can be imposed both on domestic and foreign companies, which conduct at least part of their business in the UK. The entity can defend itself by proving that it took adequate precautions and implemented adequate procedures to prevent misconduct.

The CMCH Act imposes homicide criminal liability on a corporate body for a gross breach of a duty of care, which caused a work-related death. Thereby the CMCH Act places an emphasis on the organizational and management failures, and it removed the identification doctrine, which was an obstacle for imposing criminal liability for manslaughter on a corporate body. According to the identification doctrine (the alter ego principle), a guilty individual (a “directing mind”) who occupies a senior position within a corporation has to be determined to attribute liability to the corporation. Unlike vicarious liability, the identification doctrine presumes that certain managers and employees act as the company itself, rather than on its behalf (Wells 1999, p. 120).

Civil Law Countries

Corporate criminal sanctions are applied in most civil law jurisdictions. Starting from 1990s many countries, which had only corporate civil liability before, actively adopted corporate criminal liability (Norway in 1991, Iceland in 1993, France in 1994, Finland and Slovenia in 1995, Belgium in 1999, Estonia and Hungary in 2001, Malta in 2002, Switzerland, Croatia, Poland and Lithuania in 2003, Slovakia and Romania in 2004, Austria 2006, Luxembourg and Spain in 2010, Czech Republic in 2011; the legislative initiative on corporate criminal liability has been introduced in Russia in 2015). Italy, Sweden, and Bulgaria have quasi-criminal corporate liability (Engelhart 2014, p. 56).

Germany

German law recognizes corporate liability imposed for wrongdoings of company representatives or employees. The German Penal Code (Strafgesetzbuch or StGB) follows the Roman rule *societas delinquere non potest*, according to which a legal entity cannot commit a crime. Criminal liability is applicable only to natural persons. Financial sanctions can nevertheless be imposed on legal entities for wrongdoings committed by corporate representatives or employees on behalf of the company (Weigend 2008; Böse 2011). These sanctions ensure that companies do not derive any benefits from the committed offenses, and they can be imposed irrespective of any criminal sanctions applied to natural persons with regard to the same offense. Corporate sanctions are justified by the standpoint that the failure to provide proper organization and supervision of corporate representatives and employees constitutes corporate guilt (Böse 2011, p. 231). The important role of organizational negligence in German law contrasts with both the no-fault enterprise liability approach, in which fault is irrelevant, and the doctrine of vicarious liability, according to which individual negligence is automatically attributed to a corporate entity (Kyriakakis 2009, p. 344).

In the German Civil Code (*Bürgerliches Gesetzbuch* or BGB), organizational negligence is interpreted in the principal-agent context. The

BGB (§823) specifies that a principal (“a person who uses another person to perform a task”) “is liable to make compensation for the damage that the other unlawfully inflicts on a third party when carrying out the task.”

France

Similar to Germany, the principle of *societas delinquere non potest* guided for a long time the approach toward corporate liability in France. Only the Penal Code (*Code pénal*) of 1992 (effective since 1994) introduced corporate criminal liability into the French law, which marked a significant shift from the idea that corporations cannot be criminally liable, which traces back to the Napoleonic Code (Coffée 1999, p. 23). Initially limited to a number of specific offenses, corporate criminal liability has been extended to all offenses and all legal persons, except from the state and local public authorities (Tricot 2014). To impose criminal liability on a legal entity, an offense has to be committed by the entity’s organs or representatives on behalf of the entity (Arts. 121–122 Penal Code).

Italy

Similar to Germany and France, the principle of *societas delinquere non potest* was dominant in the Italian law for a long time. Article 27(1) of the Italian Constitution states that criminal liability is personal, which implies that criminal law applies only to natural persons. Some European and OECD conventions, however, require the states which comply with these conventions to enact corporate liability. This fact induced Italy to enact Decree no. 231 (*Decreto Legislativo no. 231*) in 2001, which introduced administrative liability of corporate entities for crimes committed by their employees.

To attribute a criminal offense to a corporation, the offense should be committed in the interest or to the advantage of the corporation (Sant’Orsola and Giampaolo 2011). Article 6 of Decree no. 231 sets out the possibility for organizational defense, allowing a company to avoid liability if it “adopted and effectively implemented appropriate organisational and management models.”

The Netherlands

Already in 1950, the Dutch law acknowledged that economic offenses can be committed not only by individuals but also by corporate bodies (the Economic Offences Act, *Wet op de economische delicten*). In 1976 criminal liability of public and private corporate bodies was introduced in the Dutch Penal Code (*Wetboek van Strafrecht*), Art. 51. Criminal liability can be imposed on a corporate body if a wrongful act or omission was committed by a corporate employee or agent within the normal course of business, given that a company benefited from the wrongful conduct and accepted such conduct or failed to take adequate precautions to prevent it (Keulen and Gritter 2011). Thus corporate liability is based on the negligence standard. To attribute liability to the corporation, it is sufficient to prove that management or multiple individuals within the corporation possessed knowledge about the criminal activity or the risks thereof, but adequate measures toward crime prevention were not taken. Collective knowledge (the *mens rea* of different individuals) can be aggregated to establish organizational fault (Coffee 1999, p. 10; Stessens 1994, p. 512). This is a distinctive feature compared to the British identification theory (Coffee 1999, p. 22).

Criminal Liability Imposed by International Conventions

Apart from national laws, corporate liability is also envisaged by international conventions. For example, the OECD Convention on Combating Bribery of Foreign Public Officials in International Business Transactions (1997), which came into effect in 1999, prescribes the imposition of criminal liability on legal persons for bribery and corrupt business practices across borders. The signatories of the Convention are obliged to enact domestic legislation conforming to the Convention's standards.

Some other international conventions, such as the International Convention for the Suppression of the Financing of Terrorism (1999), the UN Convention Against Transnational Organized Crime (2000), and UN Convention Against Corruption (2003), also foresee corporate liability.

Moreover, International Standards on Combating Money Laundering and the Financing of Terrorism and Proliferation are an important soft law instrument that contains provisions on corporate criminal liability.

Panel Data Analysis

Aitor Ciarreta, María Paz Espinosa and
Ainhoa Zarraga
University of the Basque Country, UPV/EHU,
Bilbao, Spain

Abstract

A panel data set is one that follows a given sample of units over time. Thus, panel data analysis refers to econometric tools that deal with the estimation of relationships that combine time series and cross-sectional data. Appropriate estimation methods are discussed depending on the characteristics of the data.

Denote by y_{it} an observation of the dependent variable for unit i at time t and x_{it} the set of K -independent variables observed for unit i at time t . Consider a linear regression model:

$$y_{it} = \alpha_{it} + \beta'_{it}x_{it} + u_{it}, \quad i = 1, \dots, N, \quad (1) \\ t = 1, \dots, T,$$

where the error term u_{it} is independently and identically distributed over i and t , and α_{it} and β'_{it} are (1×1) and $(K \times 1)$ vectors of parameters to be estimated.

This model cannot be estimated because the degree of freedom, NT , is less than the number of parameters to be estimated, $NT(K + 1)$.

Therefore, a structure needs to be imposed. Assuming constant parameters over time, the basic initial test is the covariance test for homogeneity across units, where three hypotheses can be made (Greene 2008; Hsiao 2003):

H₁: Both intercept and slope coefficients are the same: $\alpha_{it} = \alpha$ and $\beta'_{it} = \beta'$.

When **H₁** is rejected, two different types of heterogeneity across units can be considered:

H₂: Slope coefficients are the same and intercept coefficients are not: $\alpha_{it} = \alpha_i$ and $\beta'_{it} = \beta'$.

H₃: Intercept coefficients are the same and slope coefficients are not: $\alpha_{it} = \alpha$ and $\beta'_{it} = \beta'_i$.

Behind the implied models underlies the assumption that the effects of the omitted variables are of two types: individual time-invariant and period individual-invariant. The simplest representation is to introduce dummy variables for specific cross-sectional units that stay constant over time and time-specific effects constant across units. There are several methods to estimate Eq. 1 depending on the structure of the model. First, assume lagged dependent variable does not enter in the equation as a regressor. Then, the fixed-effects (FE) and the random-effects (RE) models are commonly used.

The FE model removes the effect of time-invariant characteristics from the explanatory variables which are unique to the unit and not correlated with other individual characteristics. Thus,

we can assess the net effect on prediction. The equation to estimate is

$$y_{it} = \alpha_i + \beta' x_{it} + u_{it} \quad i = 1, \dots, N, \quad (2)$$

$$t = 1, \dots, T.$$

The least-squares dummy variable estimator, also called the within-group estimator, is obtained applying OLS to Eq. 2 in which variables have been previously transformed to subtract the corresponding time series means. This estimator is unbiased and consistent when either N or T or both tend to infinity.

The RE model, on the contrary, assumes that the variation across units is random and uncorrelated with the independent variables included in the model:

$$y_{it} = \alpha + \beta' x_{it} + v_i + u_{it} \quad i = 1, \dots, N, \quad (3)$$

$$t = 1, \dots, T,$$

where v_i is the between-individual error term. It is assumed that v_i is not correlated with the explanatory variables. If you have any reason to believe that differences across units have some influence on the dependent variable, then random effects are more appropriate. An advantage of RE is that you can include time-invariant variables, whereas in the FE model, these variables are absorbed by the intercept.

In Eq. 3, OLS estimator is inefficient because the error term is correlated. In this case, GLS gives an efficient estimator.

The choice between FE and RE can be performed using the Hausman test where the null hypothesis is that the best model is RE.

There are other tests the analyst has to perform before choosing one model or the other. If the FE model is selected, then test whether time-fixed-specific effects, λ_t , are needed. If they are needed, then the model to estimate is

$$y_{it} = \alpha_i + \lambda_t + \beta' x_{it} + u_{it} \quad i = 1, \dots, N, \quad (4)$$

$$t = 1, \dots, T.$$

The basic model can be extended in several directions. Assume that T is large enough, then

the model is dynamic in nature and lagged dependent variables may be included:

$$y_{it} = \gamma y_{i,t-1} + \alpha_i + \lambda_t + \beta' x_{it} + u_{it} \quad \text{where}$$

$$i = 1, \dots, N \text{ and } t = 1, \dots, T. \quad (5)$$

Finally, another extension is to assume variable coefficient models:

$$y_{it} = \sum_{k=1}^K \beta'_{kit} x_{kit} + u_{it} \quad \text{where}$$

$$i = 1, \dots, N \text{ and } t = 1, \dots, T. \quad (6)$$

Passive Minority Interests

Nikolaos E. Zevgolis and Panagiotis N. Fotis
Hellenic Competition Commission, Athens,
Greece

Abstract

Passive minority interests consist of various types of non-controlling interests in competitors, such as minority shareholdings and interlocking directorships. Loans and other financial products involving competitors may also play a crucial role in creating mutual interactions among the parties. A minority interest is the portion of a consolidated entity that is not owned by the consolidating entity. A consolidated entity may be formed through management/shareholding control and also depends on the prevailing accounting/regulatory environment.

passive minority shareholder may be in a position to receive direct information regarding the victim firm's main operations. In such a case, despite the fact that the practical ability of the owner of the passive minority interest to have access to this kind of information is not enough to enforce him influencing the strategic behavior of the victim firm, it is adequate to provide him with a sort of control over the victim firm (OFT 2010).

Acquisitions of non-controlling minority interests in a rival may also reduce the quality of the product. However, economically speaking, the said links are less likely to trigger unilateral and coordinated effects than full acquisitions or acquisitions of minority shareholdings that influence the strategic behavior of the target firm.

Passive minority interests consist of various types of non-controlling interests in competitors, such as minority shareholdings and interlocking directorships. Loans and other financial products involving competitors may also play a crucial role in creating mutual interactions among the parties. Generally speaking, a minority interest is the portion of a consolidated entity that is not owned by the consolidating entity. A consolidated entity may be formed through management/shareholding control and also depends on the prevailing accounting/regulatory environment.

Synonyms

Non-controlling minority interests

Introduction

Passive or non-controlling minority interests (minority shareholdings and interlocking directorships) among competitors of oligopolistic markets are links that tend to raise the price and reduce the quantities sold in the market, even in cases where a cartel, tacit or explicit, is not detected. Such links may force competitors to compete less vigorously and adopt behavior more conducive to joint profit maximization by facilitating price and other strategic information sharing among them. This may be happening because there are cases where a

Minority Shareholdings

Minority shareholdings among firms refer to situations where shareholders hold less than 50% of the voting rights of other firms' equity capital. That is, they are portions of a consolidated entity which do not confer control in the legal sense to their owners and are therefore not notifiable under the worldwide merger notification systems. Minority shareholdings are also called structural links (SWD 2014a, Annex 1 and 6).

Active or Passive Minority Shareholdings

Minority shareholdings may be either *active* (controlling) or *passive* (non-controlling) in nature. Active minority shareholdings refer to minority interests where their owner, a person or a firm, may exercise some form of control over the

victim firm(s) (i.e., the issuing firm of the asset or claim for which a minority interest is established). Passive minority shareholdings refer to situations where a minority shareholder cannot be represented in the decision-making bodies of the issuing firm. They constitute purely passive financial interests. However, there are circumstances where a passive minority shareholder may receive direct information about an issuing firm's main operations. Even though the practical ability of the passive minority shareholder to have access to this kind of information does not provide him with the potential to influence the strategic behavior of the issuing firm, it does provide a sort of control over this firm.

Pre-existing Minority Shareholdings

Pre-existing minority shareholdings exists in the context of a notified transaction and therefore may be analyzed regarding its anti- or/and pro-competitive effects within the notified transaction. For instance, a national competition authority or the Commission could order the divestiture of the pre-existing minority shareholding in the case that it is found to be anticompetitive. Where a minority shareholding is acquired after the examination of a notified transaction, the competition authority lacks the competence to review this acquisition.

Horizontal or Non-horizontal Minority Shareholdings

Horizontal minority shareholdings are minority shareholdings in horizontal competitors, while *non-horizontal* minority shareholdings are interests either between firms operating at different levels of the supply chain (*vertical* minority shareholdings) or between firms that are neither purely horizontal nor purely vertical (*conglomerate* minority shareholdings).

Direct or Indirect Minority Shareholdings

When a firm holds a *direct* minority shareholding in another firm it means that it holds it directly without the intervention of a third firm. However, an *indirect* minority shareholding exists when a firm holds a minority shareholding in another firm via the intervention of a third firm.

One-Way or Reciprocal Minority Shareholdings

If both firms hold shares in one another equity capital, then the minority shareholding is called *reciprocal* minority shareholding. The opposite of reciprocal minority shareholding is the *one-way* minority shareholding.

Interlocking Directorships

Interlocking directorships refer to situations where horizontal and nonhorizontal (e.g., vertical) competitors share on boards of directors one or more directors, top executives, nonexecutives, managers, and close relatives, e.g., spouses and parents. Competitive concerns may be stronger in cases where interlocking directorships involve managers rather than directors since the former may more easily understand the day-to-day organization of the issuing firm than the latter and therefore enjoy more decisive influence over its strategic behavior in the interest of their employers.

Types of Interlocking Directorships

As in the case of minority shareholdings, there exist various forms of interlocking directorships such as active or passive, horizontal or non-horizontal, direct or indirect, and one-way or reciprocal interlocking directorships. Except from these basic types, there exist other types of interlocking directorships between firms. For example, in some circumstances firms' officers may hold a seat on the board of directors of competitors. This type of directorship is called *management interlock* (Arreda and Turner 1978). However, there are competitors that share common officers without involving directorships. This type of interlock seems not to raise competition concerns and it is called a *manager to manager interlock* (O'Brien and Salop 2000).

Passive Minority Interests and Competition Law

In a Nutshell

As a general rule, active or controlling minority shareholdings fall under the scope of merger

notification systems, while passive or non-controlling minority shareholdings are not subject to the majority of control systems found worldwide. Against the backdrop of the Council Regulation (EC) No. 139/2004 (*The EC Merger Regulation*), the Commission cannot examine minority shareholdings in stand-alone investigations. Nevertheless, in some national merger laws, there are provisions regarding the acquisitions of minority shareholdings in competitors (see, for instance, Germany, United Kingdom, Austria, and Lithuania), but the majority of them do not incorporate such provisions in their merger notification systems. In that case, the regulation of passive minority shareholdings falls under the mechanism of antitrust law. Preexisting minority shareholdings constitute exceptions to this rule.

Passive Minority Interests and Mergers and Acquisitions

Active along with pre-existing minority shareholdings are the only forms of minority interests that fall under the scope of the Merger Regulation 139/2004. More specifically, active minority shareholdings fall directly under the scope of this Regulation; preexisting minority shareholdings fall indirectly under the scope of the same Regulation. A few merger cases in EU (see, *inter alia*, IV/M.042 *Alcatel/Telettra*, IV/M.113 *Courtaulds/SNIA*, IV/M.833 *Coca-Cola/Carlsberg*, IV/M.890 *Blokker/Toys “R” Us On 23*, IV/M.1082 *Allianz/AGF*, IV/M.1378 *Hoechst/Rhône-Poulenc*, IV/M.1383 *Exxon/Mobil*, IV/M.1453 *AXA/GRE*, IV/M.1673 *VEBA/VIAG*, IV/M.1940 *Siemens/Framatome/Cogéma*, COMP/M.1980 *Volvo/Renault*, COMP/M.2050 *Vivendi/Seagram*, COMP/M.2567 *Nordbanken/Postgirot*, COMP/M.3547 *Banco Santander/Abbey National Transactions*, COMP/M.3653 *Siemens/VA Tech*, IV/M.3696 *E.ON/MOL*, COMP/M.4150 *Abbott/Guidant*, COMP/M.4153 *Toshiba/Westinghouse*, COMP/M.4439 *Ryanair/Aer Lingus*, COMP/M.5096 *RCA/MAV Cargo*, COMP/M.5406 *IPIC/MAN Ferrostaal*, COMP/M.6541 *Glencore/Xstrata*, COMP/M.6662 *Andritz/Schuler*) constitute examples where a party to a transaction has pre-existing structural links to competitors or other firms and where the

parties quite often offered to divest these minority shareholdings with the intention of remedying the competition concerns raised by the transactions.

An active minority shareholding exists if the major prerequisites of the EU Merger Regulation are satisfied. In particular, the merger notification system in the EU is based on three pillars: (i) the notion of concentration, (ii) the existence of acquisition of control, and (iii) the dimension of the notified transaction. According to the Commission Consolidated Jurisdictional Notice under Council Regulation . . . (2008), para 7, “a concentration only covers operations where a change of control in the undertakings concerned occurs on a lasting basis.” So, “the concept of concentration is intended to relate to operations which bring about a lasting change in the structure of the market.” The notion of concentrations also applies to joint ventures, which perform “on a lasting basis all the functions of an autonomous economic entity.”

In terms of European law the concept of concentration cannot be extended to cases in which control has not been obtained and the shareholding at issue does not, as such, confer the power of exercising decisive influence on the other undertaking. However, the European Commission seems to support the need to extend Regulation 139/2004 to the acquisition of non-controlling minority shareholdings (see SWD 2014a, 221, para 62).

Passive Minority Interests and Anticompetitive Practices

In General

Articles 101 and/or 102 of the Treaty on the Functioning of the European Union (TFEU) may apply to passive minority interests in situations where there is evidence of an anticompetitive agreement or concerted practice among the investigated firms or the firms that are engaged in the acquisition of non-controlling stakes and/or one or more firms have a dominant position. Nevertheless, according to the Commission Staff Working Document (SWD 2014a, 221), “the Commission’s ability to use Article 101 and Article 102 TFEU to intervene against anti-competitive minority shareholdings may be limited.”

More specifically, in its *White Paper* and the accompanying Commission Staff Working Paper of July 2014, the Commission states that an acquisition of a minority shareholding may not constitute an agreement which by object or effect restricts the effective competition. As a consequence, it may not be possible to intervene in cases that involve potentially anticompetitive minority shareholdings. Furthermore, regarding Article 102 TFEU, the Commission states the same argument unless the acquirer or the issuing firm or both of them have a dominant position in the markets under scrutiny (see White Paper (2014b) para 40; SWD (2013) 239, Annex II, p 6, and SWD (2014a) 221, para 62).

Application of Article 101 TFEU

In some cases, an agreement which by object or effect restricts the effective competition and violates Article 101 TFEU does not exist. For instance, acquisitions of minority interests via a stock exchange may not contain an agreement among the firms of the sellers and the buyers. In this case, a memorandum among shareholders and/or particular firms' articles covering their relationship may be viewed as an agreement under Article 101 TFEU. Generally speaking, stock market acquisitions of minority shareholdings involve an agreement between the firm, who acts as a purchaser, and the shareholder(s) of a firm, who act as the seller(s) or the issuing firm in the transaction. In this transaction, the difficulty which arises for assessing the potential anticompetitive effects of such an acquisition is that the firm is not (at least typically) a participant in the transaction. Therefore, an agreement between the two firms does not exist.

On the other hand, an agreement between the two firms does exist if the corporate bodies of the two firms are involved directly in the transaction. Furthermore, Gilo et al. (2006) have proved that a controlling shareholder (whether a person or a parent corporation) can facilitate tacit collusion further by making a direct passive investment in rival firms. Such investment particularly facilitates collusion if the controller has a relatively small stake in his own firm.

Potential Application of Article 101 TFEU in

Combination with Application of Article 102 TFEU

The establishment of coordinated effects (see section "[Coordinated Effects of Passive Minority Interests](#)") as a consequence of an acquisition of passive minority interests implies that the firms engaged in the transaction coordinate their strategic behavior, i.e., they raise prices and harm effective competition. Coordination may occur by firms that prior to the acquisition did or did not coordinate their behavior. In the former case, a minority shareholding may make coordination more effective and easier.

An acquisition of a minority shareholding may serve as an instrument for influencing the commercial or strategic policy of a direct competitor (especially in the case where reciprocal minority shareholdings exist), or it may enable the acquiring firm to acquire control over the acquired firm at a later stage. In that case, even though the acquisition of minority shareholding does not lead by itself to a restriction of competition for the purposes of Article 101 TFEU, i.e., it has neither the object nor the effect of distorting competition by creating the premises for cooperation and/or exchange of commercially sensitive information among the engaged firms, its potential impact on competition in the long run can be seen as an agreement which violates Article 101 TFEU.

As a consequence, such structural links may eliminate the incentives of the competitors to compete with each other in the market(s) in which they carry out business (Levy 2014). As well as potential commercial cooperation among firms engaged in a minority shareholding transaction, there are other factors that may serve in this direction. For instance, providing that the market under scrutiny is an oligopolistic market, such factors are barriers to entry and the ability of the acquiring firm to achieve effective control (legal or de facto) over the commercial and strategic policy of the acquired firm.

In particular, the level of concentration in the market under scrutiny plays a critical role in the existence or not of coordinated behavior. The rule is that the higher the level of concentration, the lower the number of the effective firms in the

market and the higher the likelihood of cooperation among them. This depends crucially on the magnitude of the influence of the strategic behavior of the acquired firm, since the more the acquiring firm knows about the target firm, the easier it is to coordinate with it in order to enhance the profits of both firms. A concentrated market enhances coordination among its players without the need for an agreement that may violate Article 101 TFEU; the possibility of collective dominance – and perhaps abuse of it under Article 102 TFEU – in such a case is quite strong. However, two factors that independently contribute to such an enhancement must be considered: firstly, the existence of reciprocal and indirect minority shareholdings among the firms in the market; and secondly, the existence or not of a maverick firm. (The existence of a maverick undertaking would probably diminish the possibility of collective dominance.) More specifically, the existence of reciprocal and indirect minority shareholdings among the firms in the market enhances the ability of the acquiring firm to monitor the strategic behavior of the target firm and at the same time the strategic behavior of all the other firms that are connected with it via the existence of minority shareholdings.

Application of Article 102 TFEU

Article 102 TFEU applies only in the case where the engaged firms in the transaction under scrutiny hold a dominant position, either independently or collectively, in the concerned relevant market(s). Therefore, an acquisition of minority shareholding requires the existence of a dominant position between the parties that engaged in it. However, in theory it has been stated that an abuse of a dominant position requires that an acquisition of a minority shareholding may serve as an instrument for influencing the commercial or strategic policy of a competitor, especially in the case where there exist reciprocal minority shareholdings in the relevant market under scrutiny (Fotis and Zevgolīs 2016).

As a matter of fact, this was the judgment of the Court of Justice in the *Phillip Morris* case. Furthermore, in the *Gillette* case the firm abused its dominant position in the relevant market of

disposable razors by acquiring a minority shareholding over its direct competitor, Wilkinson Sword. Gillette had become the main shareholder and creditor of Eemland (the owner of Wilkinson Sword) and could have used its rights to prevent future concentration plans that Eemland would have had, and Gillette would not have approved of. Therefore, in the *Gillette* case the European Commission established an infringement of Article 102 TFEU since the transaction had altered the structure of the market under investigation.

The Economics of Passive Minority Interests

The majority of relevant research in the literature indicates that non-controlling minority interests decrease the level of competition in the markets by enhancing cooperation among rivals or by increasing the probability that a dominant firm will abuse its dominant position. In any case, passive minority interests decrease consumer welfare by increasing the product price and reducing its quantity.

The Anticompetitive Effects of Passive Minority Interests

Economic literature has shown that passive minority interests among rivals (*horizontal passive minority interests*) harm competition either unilaterally or via coordinated effects. The magnitude of these effects depends on the share of the issuing firm's profits to which the acquiring firm is actually entitled as a result of the non-controlling acquisition, and the ability of the acquiring firm materially to influence the issuing firm's strategic behavior. If passive minority interests are accompanied by interlocking directorships, then such interests may alter the competitive behavior of both acquiring and target firm.

The anticompetitive effects of *nonhorizontal passive minority interests* have also been examined in the economic literature. *Vertical passive minority interests* impose input (upward) or customer (downstream) exclusion. *Conglomerate passive minority interests* enhance anticompetitive

issues if the acquiring firm acquires a non-controlling minority stake in the issuing firm which is active in a market related to that of the acquiring firm. A conglomerate non-controlling minority interest may promote acquiring firms' sales of one product contingent on the sales of other products via *bundling*, *tying*, *exclusive dealing*, or *full-line forcing*.

Non-controlling minority interests may block entry both for potential entrants that are not active in the market or for active firms in the market that are interested in expanding their product range. Also, acquiring firm hinders another firm from getting an access to the capital stock of the issuing firm. For instance, in the Aer Lingus/Ryanair case Aer Lingus argued that Ryanair's non-controlling minority interest on its capital stock had a material impact on Aer Lingus's shares, by making them less attractive to potential buyers (*Case T-411/07, "The Ryanair Decision"* and *Case T-342*07 Ryanair v Commission*). However, it should not be ignored that the attractiveness of Aer Lingus on the stock market is not based solely on Ryanair's non-controlling minority interest (SWD 2014a, 221).

Furthermore, the acquiring firm has an enhanced incentive to deter entry by credibly committing to the potential entrant. If the non-controlling minority interest is accompanied by corporate rights, then the commitment is stronger that further prevents a potential entrant from entering to the market. However, if non-controlling reciprocal minority interests are prohibited (allowed), then entry will be deterred (promoted) if the relevant products are complements (substitutes) (Clayton and Jorgensen 2005).

Unilateral Effects of Passive Minority Interests

The anticompetitive effects of non-controlling minority interests are stronger on the horizontal than on vertical level. On the former, they change firms' strategic behavior in favor of coordination among them. If the acquiring firm has an incentive to compete softly with its competitor, may raise its product price or restrict its output (see, *inter alia*, Reynolds and Snapp 1986; Bresnahan and Salop 1986; Farrell and Shapiro 1990; Shelegia and Spiegel 2012).

In a static environment, the acquiring firm abuse part of the issuing firm's diverted sales via its non-controlling minority stake. In this scenario, the degree of competition between the two firms and the amount of sales that diverted to the competitors are of high importance. The more the rivalry between firms, that is the case of close substitute products, the more the diverted sales that are captured by the issuing firm after an increase of acquiring firm's product. This is called *Diversion Ratio*. In duopolistic markets, the *Diversion Ratio*, in absolute terms, is the ratio of the cross-elasticity of demand for firm's A product when firm B raises its product price divided by the own-elasticity of demand for firm's B product multiplied by the ratio of unit sales by firm B divided by the unit sales by firm A (Fotis et al. 2017). Therefore, the acquiring firm earns profit, the magnitude of which depends on the non-controlling minority interest in the capital of the issuing firm.

Vertical passive minority interests harm competition by imposing input (upward) or customer (downstream) exclusion. If they are accompanied by corporate rights, then the acquiring firm gains the ability to exclude the issuing firm's competitors from its input and customer base. The more concentrated the markets are, the more the concerns for either type of exclusion. The acquiring firm's incentive to exclude competitors is higher through corporate rights than through solely financial interests. If the acquiring firm gains access to strategic data of the issuing firm, then the gains from exclusion are more than the gains accrued from a vertical merger. The acquiring firm internalizes the whole stream of profits that come from the other levels of supply chain and at the same time incurs only a small portion of the costs caused by the anticompetitive strategy (see, *inter alia*, Flath 1989; Greenlee and Raskovich 2006).

An example of vertical passive minority interest at the European Union (EU) level is the case *COMP/M.5406 IPIC/MAN Ferrostaal*. In this case, MAN Ferrostaal (the acquiring firm) held a non-controlling minority stake in Eurotecnica (the issuing firm), a provider of technology and engineering services. The EU Commission was

concerned that the acquiring firm would determine the technology licenses distribution by the issuing firm and thus excluded (potential or active) competitors from the market. The suggested remedy by the EU Commission in order to clear the case included the divestiture of the non-controlling minority interest held by MAN Ferrostaal in Eurotecnica (SWD 2014a, 221).

Coordinated Effects of Passive Minority Interests

Non-controlling minority interests also enable involved firms to coordinate their conduct. Through coordination the acquiring firm internalizes part of the issuing firm's profit. Moreover, the level of transparency is enhanced in the presence of corporate rights. On the one hand, in the case of one-way acquisition of information from the issuing to the acquiring firm (*unilateral passive minority interest*), the acquiring firm has the ability to monitor the commercial policy of the issuing firm. If, on the other hand, a reciprocal minority shareholding exists, then the level of transparency is enhanced more than the previous case (see, *inter alia*, Malueg 1992; Reitman 1994; Gilo et al. 2006; Brito et al. 2013).

A market becomes more transparent when *indirect non-controlling minority interests* are accompanied by corporate rights. Such interests enlarge the scope of coordination and enable the coordinating firms to detect possible deviations from the common target which aims at maximizing the monopoly profits (*IV/M.1673 V EBA/VIAG*).

Pro-competitive Passive Minority Interests and Efficiencies Gains

Non-controlling minority interests raise arguments in favor of efficiencies. Clayton and Jorgensen (2005) analyze reciprocal minority interests in a duopoly Cournot market, and they state that consumer surplus and firms' profits with complements products are enhanced more when the said interests are allowed rather than when they are prohibited. If the products are substitutes, then firms' profits are enhanced when passively acquired interests are prohibited rather than when they are allowed. On the contrary, consumer

surplus is enhanced when non-controlling minority interests are allowed.

Brito et al. (2014) argue that consumer surplus is enhanced by turning voting shares (shares with control rights) into nonvoting shares (shares with no control rights). Moreover, the sale of voting shares to a new large shareholder is better than the sale of voting shares to a series of small shareholders. The authors agree with the main results of O'Brien and Salop (2000), but also consider that a financial interest affects not only the incentives of the acquiring but also the incentives of the acquired firm (see also *COMP/M.2416 Tetra Laval/Sidel*).

Passive minority interests enable the transfer of technology and managerial skills and the creation of synergies among firms which positively influence firms' profits (Ono et al. 2004). Amundsen and Bergman (2002) argue that cost reduction through sales cooperation and learning, such as information about production process, are also, *inter alia*, motives which enable a firm to acquire non-controlling minority interests in their rivals' capital stock.

Patent Litigation

Elisabetta Ottoz

Department of Economics and Statistics Cognetti
De Martiis, University of Turin, Turin, Italy

Abstract

Patent litigation refers to patent infringement lawsuits or revocation proceedings. Infringement is the act of making, using, selling, or offering to sell a patented invention without the permission of the patent owner. Revocation proceedings refer to the claim on patent validity before civil courts that may be carried out by firms interested not to be sued for infringing “wrongly” granted patents. Presently, national courts of the member states of the European Patent Convention are competent to pass judgment on the infringement and validity of European patents, with inevitable consequences in terms of duplication and inconsistencies. In December 2012, the European Parliament approved the EU unitary patent package, whose ratification by the individual member states will give rise to a European patent with unitary effects in all jurisdictions involved and to the creation of a Unified Patent Court (UPC) with exclusive jurisdiction to hear infringement and invalidity actions. The result will be a patent protection for all participating member states based on a single application and validation.

Synonyms

[Patent annulment](#); [Patent infringement lawsuit](#)

Definition

Patent litigation refers to patent infringement lawsuits or revocation proceedings. Infringement is the act of making, using, and selling a patented invention without the permission of the patent owner. Revocation proceedings refer to the claim on patent validity before civil courts.

Introduction

A patent is the exclusive right granted by a government to an inventor to manufacture, use, or sell an invention for a certain number of years in exchange for detailed public disclosure of the invention itself so as to encourage research and development activities fostering knowledge dissemination.

In order to be patentable, an invention must satisfy some requirements concerning novelty, usefulness, and nonobviousness (WIPO 2008).

A patent is not a perfect protection against imitation, but it grants the patent holder the right to sue intruders once they have been identified. Conversely third parties have the right to challenge the validity of patents granted by the patent authority.

Patent litigation can thus take two distinct forms: infringement or revocation proceedings.

Patent infringement is the act of making, using, selling, or offering to sell a patented invention without the permission of the patent owner. The economic significance of a patent depends on its scope: the broader the scope, the larger the number of competing products and processes that will infringe the patent. The claims contained in the application are the basis of the extent of patent protection as they determine what third parties are legally allowed to do.

Revocation proceedings refer to the claim on patent validity before civil courts that may be carried out by firms interested not to be sued for infringing “wrongly” granted patents, either autonomously or as a counterclaim in a cause for patent infringement.

Proceedings before a national tribunal for revocation as part of patent litigation are not to be

confused with patent opposition, which is an administrative procedure contained in the article 99 of the European Patent Convention allowing third parties to question the validity of a patent granted by the European Patent Office (EPO) within 9 months from the its publication. Patent opposition applies to the European patent at the European-wide level, whereas revocation proceedings within litigation apply to national jurisdictions.

Infringement and validity of European patents are currently under the jurisdiction of national courts and authorities of the member states of the European Patent Organisation.

Despite the Directive 2004/48/EC of the European Parliament and of the Council of 29 April 2004 on the enforcement of intellectual property rights, relevant differences still exist as patent litigation and court judgments on validity and infringement vary significantly from one country to another (EPO 2013a). In practice, this gives rise to a number of shortcomings: high costs, risk of diverging decisions, and lack of legal certainty (Luginbuehl 2011).

The European patent system is currently undergoing major reforms aimed at overcoming existing fragmentation, which becomes increasingly problematic as innovation and industrial R&D has assumed a global scope. In December 2012, the European Parliament approved the EU unitary patent package, whose ratification by the individual member states will give rise to a European patent with unitary effects in all jurisdictions involved and to the creation of a Unified Patent Court (UPC) with exclusive jurisdiction to hear infringement and invalidity actions.

Institutional Features

European inventors can obtain patent protection by filing several national applications or, alternatively, one patent application to the EPO in which several States adhering to the 1973 European Patent Convention (EPC) are designed. The granting of a European patent allows the applicant to achieve a bunch of patents treated as independent rights, each having a limited scope: whether or not

the national parts of the European patent are infringed or invalid is then determined based on the national laws of the respective member states of the European Union.

Relevant institutional differences among the jurisdictions still exist concerning several aspects such as the existence of bifurcation, remedies for patent infringement, forum shopping, and the allocation of legal costs as illustrated by Graham and Van Zeebroeck (2014).

Bifurcation

In terms of institutional settings, a major difference relates to whether litigants are permitted or required to address infringement and invalidity claims within the same court and suit or, as in a bifurcated system, infringement is heard and determined separately from validity.

The German system is a bifurcated one: invalidity challenges, either standalone invalidation challenges or appeals of decisions rendered by the German Patent Office, can only be brought to the Federal Patent Court, whereas infringement actions can be lodged in any of the twelve competent district courts. In the French, British, Dutch, Italian, and Belgian systems, patent infringement and invalidity actions, either for national patents or for national validations of patents granted by the EPO, are brought to the same court.

The bifurcated patent system is positively considered because of quick decisions and low costs, but it might be potentially biased toward the patentee in two ways. The fast infringement proceedings in the regional courts mean, in fact, that it is possible to get to an injunction before the patent can be invalidated by the slower invalidity courts. In addition, a bifurcated system is subject to the so-called Angora cat problem: the patentee will argue for a narrow interpretation of his claim when defending the patent but an expansive interpretation when asserting infringement.

Injunctions

If a patent holder discovers that his/her patent is being infringed by products or services belonging to other parties, he/she faces the decision to file a

lawsuit and, following that, either to engage the alleged infringer in a pretrial settlement negotiation or to file suit in court claiming damages for the infringement.

The TRIPS Agreement generally provides for injunctions and damages as a remedy to patent infringement, but the specific procedures and standards for awarding these remedies are left to the member states, which apply different conditions and thresholds.

Courts in several member states allow in principle preliminary injunction, which is granted very early in a court action and restrains the defendant from infringing the patent during the pendency of litigation (Cotter 2011).

If a preliminary injunction is issued, the plaintiff will nearly always have to post a bond for securing any costs or damages caused to the defendant in case infringement is not proved. The amount of the bond is left to the court's discretion.

If the plaintiff wins at the trial, the preliminary injunction usually becomes permanent, but if the defendant wins, the preliminary injunction is removed.

Cross-border preliminary injunctions forbidding accused infringers from practicing the litigated patents both in the domestically and abroad have been applied in the Dutch litigation system with the result of a "forum shopping strategy," as patent holders may stop infringement of their patent throughout Europe.

Belgium too has become a preferred venue for patent owners who wish to quickly enforce their patent rights: Belgian courts assume, in fact, in their preliminary injunctions the *prima facie* validity of the patents, even when an opposition was pending or appealed at the EPO.

Damages

Most jurisdictions provide for three "standard methods" for damages assessment based on the calculation of lost profits, reasonable royalty, and infringers' profits (unjust enrichment) (Reitzig et al. 2007).

In the case of lost profits, the patentee shall be reinstated in a position where he/she would have been but for the infringement. The calculation

method is accepted by all major jurisdictions (USA, Japan, Germany, UK, and France).

In the US jurisdiction, the patentee, in order to be awarded lost profits, has to show causation, establishing that "but for" the infringement, she would have made additional profits. In 1978, the Court of Appeals for the Sixth Circuit put forth a test designed to determine whether a patent holder is entitled to recover for lost profits by the infringement (*Panduit Corp. v. Stalin Bros. Fibre Works, Inc.*, 575 F.2d 1152, 1156 (6th Cir. 1978)).

It is a four-step test requiring that the patentee establishes (1) the demand for the patented product, (2) the absence of noninfringing substitutes, (3) the manufacturing and marketing capability to exploit the demand, and (4) the amount of profit that would have been made absent the infringing product.

Assuming that the four Panduit conditions are met, lost profit evaluation requires to infer how the market would have evolved absent infringement and to compare the hypothetical behavior of both the patentee and the infringer with their actual behavior. The difference between the "but for" and the actual profit represents the patent holder's lost profit damage.

Proof of damages is simpler when the patentee and the infringer compete in a two-supplier market, notwithstanding a market share analysis can be used even in case of several firms in the market in order to determine a measure of lost profit award.

Once lost sales are determined, total lost profits can be calculated by measuring the incremental profits on lost sales plus profits lost on price erosion.

To the extent the patentee does not satisfy "but for" causations required by the Panduit steps, he is entitled to a reasonable royalty. The courts attempt to reconstruct the hypothetical bargain that the parties would have negotiated had they willingly tried to do so at the time infringement began. A hypothetical negotiation between a willing licensor and a willing licensee is imagined generally relying on fifteen factors set forth in *Georgia-Pacific Corp. v. United States Plywood Corp.* (1970).

The case law has established a few guiding principles that should be present in any reasonable royalty determination: first of all the best measure of reasonable royalty is an established royalty rate in the industry; second the hypothetical negotiation takes place at the time the infringement began, meaning that infringers' sunk cost are not part of the infringer's anticipated profits; and third, the patentee need not prove any actual harm to be entitled to a reasonable royalty (Frank and DeFranco 2000).

A damage award can be composed of lost profits and a reasonable royalty as, for instance, in the case where lost profits include lost sales for which the patentee had manufacturing capacity, while a reasonable royalty accounts for additional sales that exceeded the patentee's manufacturing capacity. In case the patent holder is a university or a research institute, the damage is entirely based on a reasonable royalty.

The third way of calculating damages relies on infringer's profits. In Germany the damage "is based on the legal fiction that in using another's patent, the infringer undertook a business on behalf of the rights-owner, who would thus be entitled to obtain all profits made from such business" (Reitzig et al. 2007). Granting "infringers' profits" is formally not allowed in France and the USA, even if the US term "unjust enrichment" may be interpreted as a rather close notion.

In case of willful infringement, in the USA, whether the damage award is in the form of lost profits or reasonable royalties, courts have discretionary authority to enhance the damage award by three times.

Courts have sometimes awarded inflated reasonable royalties that do not reflect the market ones, but rather imply a deterrent function against future infringements (Love 2009).

Choice of Fora

When a patent infringement suit involves a defendant domiciled in an EU member state, national courts of member states must exercise jurisdiction in accordance with Articles 2 and 5(3) of the Brussels Regulation. Under this regime, a plaintiff may bring an action in the courts of the defendant's domicile or in the state(s) in which the

alleged infringing product was manufactured or commercialized in breach of a local patent. Dutch courts have even exercised jurisdiction over foreign defendants for violations of foreign patents.

This means that patent litigants in Europe are permitted a choice of fora, which gives rise to an opportunity to engage in "forum shopping," a strategic choice of court venues in order to obtain a favorable outcome leading to economic inefficiencies. Parties try to take advantage of differences in national courts' interpretation of European patent law and in procedural laws, as well as of differences in speed and in the amount of damages awarded.

"Forum shopping is a common practice in the USA too, as any civil action for patent infringement may be brought in the judicial district where the defendant resides or where the defendant has committed acts of infringement and has a regular and established place of business" 28 USC. § 1400 (Lemley 2010).

The Allocation of Legal Costs

Two main systems for allocating litigation costs are applied, namely, the "American system," where each party bears its own costs, and the "British system," where the loser incurs all costs. In an intermediate position lie the systems which allow a partial fee shifting.

The legal-cost allocation rule plays a role in favoring patent litigation or settlement and bears implications on the royalty-bargaining process.

The Unified Patent Court

In order to overcome duplication and inconsistencies, in December 2012 the European Parliament approved the EU unitary patent package, whose ratification by the individual member states will give rise to a European patent with unitary effects in all jurisdictions involved, that is to say subject to the same legal conditions in all member states. The result will be a patent protection for all participating member states, except Italy and Spain, based on a single application and validation putting an end to validations and litigation of the patent in each state.

A Unified Patent Court (UPC), with exclusive jurisdiction to hear infringement actions, invalidity actions and counterclaims, and actions for provisional and protective measures and injunctions for litigation relating to European patents and European patents with unitary effect (unitary patents), will be created considering a transitional period of 7 years during which actions of litigation may be brought before national courts (Agreement on a Unified Patent Court and Statute 2013b)

The UPC will comprise a court of first instance, a Court of Appeal, and a registry. The court of first instance will be composed of a central division (with seat in Paris and two sections in London and Munich) and by several local and regional divisions in the contracting member states to the Agreement. The Court of Appeal will be located in Luxembourg.

Generally, claimants will bring action for revocation before the central division and will bring actions for infringement before a local/regional division in a member state in which the infringement has occurred or where the defendant is domiciled.

The system allows for a choice between bifurcation – the separation of infringement and validity claims into separate court actions as in the German system – and an integrated process for hearing infringement and invalidity cases: the regional courts have, in fact, the discretion to refer counterclaims for revocation raised by the defendant to the central division.

Where a decision is taken finding an infringement of a patent, the Court may grant an injunction against the infringer aimed at prohibiting the continuation of the infringement.

As for the award of damages Art. 68 of the UPC states:

1. The Court shall, at the request of the injured party, order the infringer who knowingly, or with reasonable grounds to know, engaged in a patent infringing activity, to pay the injured party damages appropriate to the harm actually suffered by that party as a result of the infringement.

2. The injured party shall, to the extent possible, be placed in the position it would have been in if no infringement had taken place. The infringer shall not benefit from the infringement. However, damages shall not be punitive.
3. When the Court sets the damages:
 - (a) It shall take into account all appropriate aspects, such as the negative economic consequences, including lost profits, which the injured party has suffered, any unfair profits made by the infringer and, in appropriate cases, elements other than economic factors, such as the moral prejudice caused to the injured party by the infringement; or
 - (b) As an alternative to point (a), it may, in appropriate cases, set the damages as a lump sum on the basis of elements such as at least the amount of the royalties or fees which would have been due if the infringer had requested authorisation to use the patent in question.

Legal costs and other expenses incurred by the successful party shall, as a general rule, be borne by the unsuccessful party.

The Agreement was signed by 25 EU member states on 19 February 2013. It will need to be ratified by at least 13 states, including France, Germany, and the UK to enter into force: at the moment, August 2014, the Agreement has been ratified by five member states.

Empirical Evidence

Characteristics and changes in the US patent litigation system have been studied by a large number of authors (Lanjouw and Schankerman 2001; Atkinson et al. 2009; Henry and Turner 2006).

Empirical evidence on patent litigation in the largest and most judicially active countries of the European Union is provided by recent studies, which give some real insights based on recent patent suits.

Graham and Van Zeebroeck (2014) analyzing a dataset of European patent litigation during 2000–2010, comprising approximately 9000

judicial patent decisions from seven European countries, show that the incidence of litigation and the bases of judicial outcomes diverge radically across the different countries and technology sectors. Relevant differences are also detected in the likelihood of patent litigants raising patent validity and infringement claims.

Litigation rates are highest in Belgium and France, whereas Germany and the UK show a low rate. Patent litigation varies widely across technology sectors, with the majority of cases in Europe focusing on patents granted for industrial processes, civil engineering, consumer goods, machinery, and transport technology.

Litigation costs significantly differ in European jurisdictions ranging from 50.000 to 200.000 € in France, Germany, and the Netherlands, but being considerably higher in the UK, 150.000–1500.000 €, which may explain the lower number of cases brought to court in the UK. It is worth noticing that the average cost in the USA is much higher ranging from 1.000.0000 to 10.000.000 €.

On the assumption that the Unified Patent Court will offer litigation at roughly the same cost level as the three largest low-cost national systems, Harhoff (2009), by utilizing different data sources, estimates that the total savings from the creation of the unified Patent Court are considerably larger than the actual operating costs, even for the most conservative scenarios. For 2013, the benefit-cost ratios would range between 5.4 and 10.5: in other words, duplication of litigation combined with high costs of litigation, in some countries, costs firms about 5.4–10.5 times more than the establishment and annual operation of the Unified Patent Court.

A comparison of 8,323 patent litigation cases across Germany, France, the Netherlands, and the UK, covering cases filed during the period 2000–2008 (Cremers et al. 2013), highlights relevant differences in the four jurisdictions concerning the number of case loads, settlement rate, average time for judgment, outcomes, characteristics of the litigants, fragmentation, sector distribution of litigants, and value of patents.

Out of a total of 6,739 cases in Germany, 5,121 are infringement cases heard by the three regional

courts covered by our study, whereas 1,618 are revocation cases. By far the number of infringement cases heard by German courts exceeds the combined number of cases in all three other jurisdictions. Depending on how cases are defined, Germany has between 12 and 29 times as many litigation cases as the UK; the difference is similar with regard to the Netherlands; compared to France, Germany has around six times as many cases.

The settlement of disputes reveals relevant differences across countries: settlement is more likely in Germany (60% of cases) as compared with UK (40%). As for cases decided by a judge, revocation is the most likely outcome regardless of whether the initial claim was for infringement or revocation in UK, whereas infringement is in Germany and the Netherlands. France is characterized by a large share of patents that is held not to be infringed, but valid.

The time lag between the filing for a claim for infringement and a first decision is less than 1 year in Germany, the Netherlands, and the UK, nearly double in France. Claims for invalidity are decided fastest in the UK (11.2 months), but take a lot longer to be decided in Germany (15 months) and the Netherlands (11.4 months). Again, invalidity cases in France take significantly longer (19.8 months) than in any other jurisdiction.

There are large differences across jurisdictions with regard to case outcomes. Infringement cases with court decision amount to about 22% in Germany, 36% in the Netherlands, 14.7% in the UK, but only 5.6% in France where most patents are held valid, but not infringed. In the UK the large share of revoked patents of cases that allege infringement, 26%, is due to the fact that, in about 60% of cases alleging infringement, the defendant counterclaims for revocation.

Also outcomes of invalidity actions differ considerably across jurisdictions. Whereas in the UK 42% of patents are revoked if the case is decided by the judge, less than half as many invalidity cases end with revocation in Germany and France. The risk of infringing a patent that forms the subject of a revocation action is very low in all jurisdictions (4% in the UK and 7% in Germany).

Fragmentation leading to parallel litigation of the same patent in multiple jurisdictions is low in Germany (2%) and France (6%), but more relevant in the Netherlands (15%) and in the UK (26%). However, as the number of cases in the UK and the Netherlands is considerably lower than in Germany, the upper bound for the share of duplicated cases lies in Germany.

As for the characteristics of the litigating parties involved in the patent cases, half of all cases involve only domestic claimants in Germany and France. The share of cases with only domestic claimants drops below 40% in the UK and the Netherlands. The data look similar for defendants, with the exception of Germany where the share of cases with only domestic defendants exceeds 60%.

By sorting litigants by type – companies, individuals, universities, public research institutes, government, as well as international institutions – the largest differences in the shares of companies and individuals involved in patent cases are found across jurisdictions rather than between claimants and defendants. France, where there are almost twice as many individuals as defendants than there are claimants, is an exception. Overall the share of companies as claimants or defendants is smallest in Germany; on the contrary the greatest share of litigants in the UK falls into the “large” category. In all other jurisdictions, micro- and small companies represent the largest share of litigants.

As for the sector distribution of litigating companies, the share of pharmaceutical companies in the UK is the highest of the four jurisdictions amounting to 30%. In Germany, in contrast, companies are concentrated in manufacturing, notably the machinery and engine industry. In the Netherlands, the share of companies in the services industry (especially finance, insurance, and real estate) stands out. France does not show a strong characterization.

The number of forward citations received worldwide, a proxy for patent value, is significantly higher for the litigated patents compared to the group of non-litigated patents.

Strategic Use of Rules

First economic analyses of patent litigation stressed the role of divergent expectations (Priest and Klein 1984) and the presence of asymmetric information (Spier and Spulber 1993) in fostering litigation.

Later models argue that patent litigation reveals important information for potential entrants (Choi 1998), analyze patent enforcement through litigation when firms have private information (Llobet 2003), and compare the two doctrines of damages, lost profit and unjust enrichment (Schankerman and Scotchmer 2001).

More recently several studies have pointed out that the litigation system is likely to play a crucial role when patents are used as assets or as legal threats. Patent litigation can then be abused to extort licensing payments by patent-assertion entities (also known as “trolls”). Trolls engage in deliberate strategies whose aim is to acquire patents of failed companies or independent innovators using them to threaten suit against alleged infringers, without having the intention of actively using the patents they assert. In particular, in component-driven industries, notably information technology, trolls engage in deliberate tactics allowing them to take product developers by surprise once they have made irreversible investments (Lemley and Shapiro 2007).

As trolling activity, though not illegally, seeks to exploit structural and procedural weaknesses of the patent and judicial system to earn rents, an optimally designed patent litigation system should minimize the room for such welfare-reducing behavior.

The significant occurrence of trolls in the USA may find its roots in the high costs of legal proceedings, cost allocation rules (each party bears its own costs), contingency fees, high damage awards, and injunctive reliefs, characterizing the US litigation procedure. Moreover, questionable examination quality in patent granting and broadly defined patentable subject matter also play a role.

The weaker presence of “trolls” in Europe is presumably because the patent systems in Europe deviate from the US system in several crucial

points. Generally, court proceedings are much less costly, cost allocation favors the winning party, damage awards are not excessive, most courts have sought a careful balance between the rights of the parties, injunctions are not issued automatically, and the quality of patent examination has been considerably better than in the USA.

However, one should not assume that the European system is troll-proof: recently patent funds have acquired patent portfolios consisting of several thousand patents, largely European ones, and may seek to enforce them (Harhoff 2009).

Conclusions

The birth of the UPC will represent a considerable progress for the management of intellectual property in the EU in order to overcome duplication and inconsistencies and to lower litigation costs. The result will be a patent protection for all participating member states based on a single application and validation with a Unified Patent Court (UPC) with exclusive jurisdiction to hear infringement and invalidity actions.

A relevant argument put forth by the proponents of the UPC is that it will also reduce strategic behavior in Europe. This may be true for forum shopping, that is to say a strategic choice of courts venue by litigants to obtain a favorable outcome: nevertheless a new form of forum shopping might be originated by the UPC if local divisions behave differently with respect of the willingness to grant EU-wide injunctions and with respect to the attitude toward bifurcation.

As for the consequences of the EU-wide injunction, it is worth stressing that it might represent an incentive for “trolling activities,” so far not so common in the EU, suggesting a cautious use of injunctions.

Patent Opposition

Alessandro Sterlacchini

Department of Economics and Social Sciences,
Università Politecnica delle Marche,
Ancona, Italy

Abstract

A patent opposition allows third parties to question the validity of the patents granted by the European Patent Office (EPO) on the grounds that they do not meet patentability criteria, do not fully disclose the invention, or extend beyond the original application. These issues are debated before an Opposition Division and, eventually, a Board of Appeal of the EPO which decides whether opposed patents are upheld as granted, amended, or revoked. The evidence indicates that these three possible outcomes are equally probable. Since the EPO decision applies to all the states designed in the application, the patent opposition represents a unique opportunity for challenging a patent's validity at European-wide level. Along with their relatively lower costs, this explains why, in Europe, patent oppositions are used by far more frequently than patent litigation.

Synonyms

Patent invalidation challenge; Post-grant patent review

Definition

A patent opposition is an administrative procedure adopted by the European Patent Office which allows third parties to challenge the validity of a granted patent on the basis of specific grounds.

Introduction

A patent granted by a public authority is presumed to be valid. This means that the patented invention

is novel, based upon an inventive step (or “nonobvious”), and susceptible of industrial application (useful). Moreover, the patent application must disclose detailed information on the invention so that a person “skilled in the art” should be able to replicate it. To control for these requirements, patent examiners should have a relatively easy and cheap access to the relevant information about the state of prior art in specific technological fields. This condition is difficult to meet for many reasons: among them, the emergence of new fields, such as those of bio- and nanotechnologies, rooted on variegated but complementary disciplines, a staggering increase of patent applications, and a growing number of claims per application (Archontopoulos et al. 2007). To be stressed is that each claim identifies a specific property right that the patent should protect and, as such, must be validated by patent examiners.

The number of patent examiners has not expanded in line with that of applications and claims, and this has determined a growing workload and backlog in patent offices. For having a granted patent at the EPO, an average of 3 years was necessary during the early 1980s, while in the early 2000s, the examination delay increased to 5 years (van Zeebroeck 2011). To avoid an excessive length of the examination process, the evaluation of each application has become less accurate, subject to possible errors, and, thus, likely to increase the number of low-quality patents susceptible of being invalidated.

A growing uncertainty about the validity of patents generates remarkable economic losses to society (Hall and Harhoff 2004). Patent holders could underinvest in some particular technologies, and their rivals could reduce investment in competing technological advances; if both subjects have already undertaken substantial investments on these activities, they will be prone to embark in costly litigation. If the cost and length of time for invalidating patents are too high, large companies with wide financial means have an incentive to inflate their patent portfolio with low-quality patents. In this way they create a strategic barrier to entry for small innovative

companies, and this will reduce the overall pace of innovation.

To avoid these negative consequences, including that faced by the companies that risk to be sued for infringing “wrongly” granted patents, an efficient and not too expensive procedure for reviewing their validity is necessary. In principle *ex post* litigation before civil courts can fix some important errors of patent offices. In practice, however, patent litigation appears to be a too costly mechanism, giving rise to extremely uneven incentives to challenge and defend issued patents (Farrell and Merges 2004): in particular, small firms and independent inventors are likely to be severely discriminated in favor of bigger and financially wealthier patent holders (Lanjouw and Schankerman 2001, 2004; Kingston 2004; Schettino and Sterlacchini 2009).

An effective and cheaper alternative to litigation is an administrative post-grant review in which informed persons or entities have the chance to disclose relevant pieces of information that were not available or not adequately taken into account during the patent’s examination and that could undermine its validity. In the following, the procedure of patent opposition before the EPO is examined along with some evidence about the frequency, the determinants, and the outcomes of oppositions.

Institutional Features

European inventors can obtain patent protection by filing several national applications or, alternatively, one patent application to the EPO in which several states adhering to the European Patent Convention (EPC) are designed. Considering the relative costs, if patent protection is sought in at least four countries, the EPO-centralized route is more convenient. The granting of a European patent allows the applicant to achieve a bunch of patents that are valid in different countries (obviously, upon having paid the national fees and translating the documents).

According to Article 99 of the EPC, within 9 months from the publication of the mention of

the grant of a European patent, any person can challenge its validity by filing an opposition against the granting decision of the EPO. Although most of the opponents are rivals of patent holders seeking to obtain the limitation or revocation of a patent, in principle, it is not necessary for the opponent to have or manifest a particular interest in the patented invention. The notice of opposition may be filed, jointly or separately, by more than one opponent.

Section 2 of the same article makes clear that “The opposition shall apply to the European patent in all the Contracting States in which the patent has effect.” Thus, in Europe, the opposition at the EPO represents a unique opportunity to challenge the validity of a patent at the European-wide level rather than in individual national courts. It should be added that only in 13 out of the 38 states adhering to the EPC, there is a procedure for post-grant patent oppositions (EPO 2013). Among the largest countries, only in Germany the patent law provides for invalidity actions in a unique national court (the Federal Patent Court) separated from other civil courts specialized in litigation for patent infringements. Instead, post-grant oppositions are not allowed in France, the UK, and Italy, while only to a limited extent in Spain. Thus, multiple suits before the civil courts of different countries could be necessary to invalidate a European patent. Compared to the centralized procedure at the EPO, such an alternative implies not only more costs (see below) but also a non-negligible level of uncertainty: in fact, it cannot be taken for granted that different national courts will achieve the same decision.

The grounds for opposition, established in Article 100 of the EPC, are the following:

1. The subject matter of the patent is not patentable (lack of novelty, inventive step, and industrial applicability, according to Articles 55–57 of the EPC).
2. The patent does not disclose the invention in a manner sufficiently clear.
3. The subject matter of the patent extends beyond the content of the filed application.

The opposition process is overseen by an Opposition Division, composed of three technical examiners of the EPO, at least two of whom must not have taken part in the proceedings for granting the opposed patent (Article 19, EPC). If the complexity or specificity of the case so requires, the Opposition Division can decide to include an additional legally qualified examiner who has not taken part in the proceedings for grant. The same requirement holds for being the Chairman of the Opposition Division. In case of parity of votes, that of the Chairman is decisive.

After 2 months from the filing of an opposition, the opponent must present his/her arguments and evidence for asking a revision of the EPO decision. Then, the patent holder has up to 6 months to reply, and the same time is allowed to the opponent for his/her counterarguments. After the exchange of observations, an oral hearing of arguments (normally open to the public) takes place before the Opposition Division. Then, the Division communicates to the parties its decision. On average, all the process is accomplished in about 22 months (Harhoff 2005).

The three possible outcomes from an opposition proceeding are the following (Article 101, EPC):

1. The opposition is rejected and the patent is upheld as granted.
2. The patent is maintained with amendments based on reformulations or cancelations of claims.
3. The patent is revoked.

The parties adversely affected by the above decisions may appeal to the EPO's Boards of Appeal, and this additional procedure can last almost 26 months. If a Board of Appeal confirms the revocation decision, the patent is invalid in all the states designated in the application. If the patent is maintained as granted, the opponents can resort to invalidity actions in the national civil courts of the designated states. In principle, the same possibility is allowed for amended patents, but the modification or cancelation of claims should reduce the likelihood of further legal disputes.

An important element that differentiates the European post-grant review from that of other countries (including the USA) is that the opposition procedure before the EPO is an adversarial process in which the legal representatives of the parties (opponent and patent holder) have the possibility of airing and debating their arguments before an adjudicator (Rotstein and Dent 2009). In this sense, an opposition proceeding resembles a validity suit before a civil court. However, while a patent litigation can be settled "out of court" (and this is what occurs in many circumstances), an opposition procedure may be continued by the EPO of its own motion even when the opposition is withdrawn (Rule 84, EPC).

Empirical Evidence

The frequency of oppositions of the patents issued by the EPO was found particularly high during the first two decades of the office's life: the average opposition rate over the period 1980–1995 was about 8% (Harhoff and Reitzig 2004). Figure 1 shows that, during the subsequent years, the share of opposed patents has constantly decreased, a part from a slight recovery in the mid of 2000s.

From 1995 to 2000, the mean opposition rate was around 6%, while between 2000 and 2012, it reduced to 5%. The last annual report of the EPO concerned with the year 2013 documents a frequency of opposition equal to 4.7%.

The decrease of the opposition rate in the last decade is due to an almost constant number of opposition cases (about 2,900 per year), while the number of granted patents has increased from 60,000 in 2003 to a record of 66,700 in 2013. However, this does not mean that to obtain a patent from the EPO is becoming easier than it was in the past.

About 60% of all applications filed at the EPO between 1980 and 2002 ended with a grant (van Zeebroeck 2011). Instead, according to the last annual reports of the EPO, over the years 2006–2012, the share of granted patents on the processed applications (through the first search on prior art and, then, the proper examination) dropped to 47%. Almost 23% of the applications

Patent Opposition,

Fig. 1 Opposition rate of EPO-granted patents: 1995–2012 (oppositions in year t on the average patents granted in year t and $t - 1$ (Source: EPO Annual Reports))

were withdrawn by the applicants after the search report, and another 30% were withdrawn or refused during or at the end of the examination process. The actual rate of refusals is not particularly high (around 5%), but it does not take into account that most of the withdrawals during the examination phase are induced by the “toughness” of EPO examiners who, by communicating detailed objections and remarks to the applicants, are able to discourage the less valuable applications (Lazaridis and van Pottelsberghe 2007).

Thus, being coupled with a remarkable drop of the share of granted patents, the observed decrease in the rate of oppositions could be a signal that the average quality of the patents granted by the EPO has improved over time giving less scope for invalidity challenges. This explanation is supported by the results of a survey jointly carried out in 2011 by Thomson Reuters and the *Intellectual Asset Management* magazine (issue of July/August 2011): the EPO was ranked first for patent quality among the world’s five largest patent offices for the second consecutive year. Compared with the Japanese and, especially, the US patent office, the EPO was leading by a wide margin in terms of perceived patent quality and also improved its position with respect to previous years. Consistent findings are provided by de Saint-Georges and van Pottelsberghe (2013) who, by using a composite index of nine variables capturing the transparency of patent systems and the quality of examinations, show that the EPO ranks first among 32 patent offices. It should be added that such a high level of real or perceived quality was not achieved at the expense of the

length in the granting process. On the contrary, in the years 2011–2012, the average delay to grant was lower than 4 years, a duration inferior to that recorded in the early 2000s (see above).

In spite of its declining trend, the rate of patent oppositions in Europe remains much higher than that of patent litigation before civil courts. Due to the presence of multiple and heterogeneous patent litigation systems among European countries, aggregate data on patent litigation at European-wide level are not available. However, some recent works have attempted to collect consistent data for some of the largest countries of the European Union.

Considering the judicial patent decisions from seven European countries published over the period 2000–2010, the litigation rate varies from a minimum of 0.1% in the UK to a maximum of 1.5% in the Netherlands (Graham and van Zeebroeck 2014). The two largest countries of the EU, Germany and France, record a frequency of patent litigation equal to 0.3% and 0.9%, respectively. These percentages underestimate the actual rate of patent disputes because those settled “out of courts” are neglected (for an analysis of patent litigation settlements in Germany, see Cremers and Schliessler 2015). However, it must be stressed that the majority of patent litigation refers to infringement rather than invalidity actions: recent data on patent litigation for France, Germany, the Netherlands, and the UK, collected from 2000 to 2008, show that only 22% of the patent disputes correspond to revocation cases (Cremers et al. 2013). As a consequence, the frequency of nullity actions before civil courts is

much lower than that of oppositions before the EPO.

The prevalence of patent oppositions as compared to invalidity litigation in Europe is mainly due to the different costs involved. Over the last decade, the total costs of an opposition before the EPO (including patent lawyers' fees) vary from €6,000 to €50,000 for each party (Mejer and van Pottelsberghe 2012). Instead, considering the proceedings before first-instance courts and patent cases of small and medium scales, the average cost of patent litigation ranges from €50,000 to €500,000, although in the UK, the maximum cost can be up to €1.5 million (EPO 2006). The country in which patent litigations are less expensive is Germany; much higher costs are documented in the UK, while France and the Netherlands record an intermediate level of litigation expenses (Cremers et al. 2013). It should be added that, in case of multiple litigation, the costs have to be cumulated across the national jurisdictions involved.

In terms of opposition rates, the differences among sectors or technological areas are remarkable. By considering the period 2000–2008, the opposition frequency of EPO-granted patent was found particularly high in the fields of chemicals and pharmaceuticals and lower in information and communication technologies (Caviggioli et al. 2013).

A large body of empirical evidence converges in showing that the opposition probability is significantly associated with the patent quality or value (Graham et al. 2003; Harhoff and Reitzig 2004; Cincera 2011; Schneider 2011). The latter can be approximated by different indicators: the most diffused and effective quality measures are the number of citations received by a patent (forward citations) and the size of patent families (given by the number of countries in which patent protection is sought for the same invention); other employed indicators are the number of backward citations (references to previous patents) and claims. The evidence suggesting that the most valuable patents (according to the above measures) are more likely to be opposed should be interpreted with some caution. In fact, an opposed patent that is revoked by the EPO cannot be

considered of high quality. A similar consideration applies to patents with many claims that could be changed or canceled at the end of the opposition proceeding. In short, what can be safely said is that only the patents that survived an opposition have a higher quality and, as such, are more likely to be successfully enforced in subsequent legal disputes for infringement (Harhoff et al. 2003; van Zeebroeck 2011).

Another interesting issue that can be examined by using patent opposition data is whether the occurrence of an opposition could be due to strategic reasons. The relevance of this question is due to the fact that patent applications are significantly concentrated in a few hands: suffice it to notice that both in 2011 and 2012, the top ten applicants at the EPO accounted for almost 11% of the total applications filed. Are patent oppositions equally concentrated? Are some companies more exposed to the oppositions filed by direct competitors or more prone to challenge the patents held by industry rivals?

Although based on narrowly defined industries, the studies that employ data for individual companies (performing both the roles of attacked patent holders and challengers) suggest that the opposition procedure is essentially a game between the major industry players (Harhoff 2005; Schneider 2011). However, this does not mean that patent oppositions between the largest companies are undertaken for pure strategic motives, such as that of creating uncertainty and inducing the rivals to delay the commercialization of innovations.

In fact, on average, only about 30% of the oppositions before the EPO ended with a patent maintained as granted, that is, with a rejection of the opposition. The prevalent outcome of the opposition proceedings has been the revocation (34%) followed by the amendment (32%) of issued patents. The residual outcome (circa 4% of cases) corresponds to oppositions that were “closed” because the opposition was withdrawn or the patent lapsed because the patent holders stopped to pay the renewal fees. It should be stressed that the percentage of opposition rejected is quite stable over time, while in some years (such as in 2012 and 2103, according to the last

annual reports of the EPO), the share of patents upheld in amended form has been above that of revoked patents. In any case, the fact that around 66% of the opposed patents end with a more or less severe reduction of the property rights of patentees clearly indicates that the opponents are more successful than the defendants of granted patents.

Concluding Remarks and Future Directions

The above findings confirm that the opposition procedure adopted by the EPO is particularly effective in correcting the errors made in the first examination process, improving the quality of granted patents, and, then, reducing the chances of further litigation. In the absence of an effective post-grant review, the only way to fix the errors of patent offices would be that of challenging the patents' validity before national courts. However, as previously stressed, the cost of a patent lawsuit is much higher than that required to pursue an opposition case before the EPO. As a consequence, this kind of administrative patent review, by reducing the scope for further and more expensive litigation, is improving social welfare.

Especially on the basis of these considerations, many scholars have contended that also in the USA, a more effective post-grant patent review, resembling that adopted by the EPO, should be introduced (Graham et al. 2003; Hall and Harhoff 2004; Farrell and Merges 2004; Graham and Harhoff 2006). The Leahy-Smith America Invents Act, enacted into law in 2011, has introduced new procedures that have a limited duration and expand the bases for challenging the patents issued by the United States Patent and Trademark Office (USPTO). These new proceedings differ from the previous USPTO reexaminations which, contrary to the EPO oppositions, have been used by far less frequently than invalidity suits before civil courts. Also in Japan, in the light of the scanty use of the invalidation system (the only means, at present, for obtaining a patent revocation), the Japan Patent Office will probably reintroduce the procedure of post-grant opposition abolished in 2003.

With respect to the important changes that are coming in the European patent system, a final consideration is in order. The unitary patent, valid for the EU countries that signed the agreement, entered into force on 20 January 2013. However, it will apply only after the entry into force of a parallel agreement on a Unified Patent Court. For the purpose of our topic, the establishment of a unified court is important because it will have exclusive jurisdiction for litigation concerned not only with the new unitary patents but also with the current European patents. Both of them will be managed by the EPO, while users will be free to opt for one of the two systems. As a consequence, the availability of unitary patents will not change the procedures that the EPO currently adopts, including the opposition and appeal proceedings. However, the Unified Patent Court will reduce the excessive costs and, especially, the risk of divergent judicial decisions which, at present, make the recourse to patent litigation in Europe particularly burdensome and unlikely. Although not in the near future, this desirable institutional change could diminish the attitude to challenge the patents' validity by mainly resorting to the oppositions before the EPO.

Path-Dependent Rule Evolution

Jan Schnellenbach

Brandenburgische Technische Universität
Cottbus-Senftenberg Chair for Microeconomics,
Cottbus, Germany

Definition

Path-dependent rule evolution occurs whenever the further change of formal or informal institutions is, at least to some degree, determined by the institutional history of a system.

How rules emerge and change

Different types of rules influence individual behavior. There are formal institutions, such as laws or self-adopted written rules of organizations (Furubotn and Richter 2005); there are informal institutions that are not captured in written form, such as social norms (Young 2008); and there are also habits or routines (Hodgson 2010; Vanberg 2002) that individuals themselves follow. A decision to implement and to follow such rules can be made consciously, but they can also evolve without any individual making a deliberate choice to change them. In any case, the evolution of rules is often path dependent.

Path dependence exists, simply put, when past events and decisions have an influence on and limit the scope of the future evolution of a system (David 2005). A simple example is the decision-making of individuals who have a preference for social approval and who attempt to infer from peer actions what the socially desired behavior is. At the initial stage, let there be a range of behaviors with roughly similar individual payoffs, so social

approval dominates the choice between them. In that case, it can happen that, given enough time, a vast majority of individuals coordinate on one type of behavior (Arthur 1994), which henceforth works like a social norm (Young 2008). It is important, however, that from the ex ante perspective, there were multiple possible equilibria, that is, various different kinds of social norms that individuals could have settled on. Path dependence implies that small differences in the early stages of the process, such as individuals randomly observing one kind of behavior rather than another, can have huge effects on the question which equilibrium is eventually chosen.

From an efficiency-oriented point of view, the biggest problem is that the equilibrium of a path-dependent selection process may not be efficient (David 1985), simply because chance and other individual motives than efficiency have driven the process. It may turn out that a different kind of norm would be, for example, associated with lower transaction costs or a more efficient utilization of technology. However, path dependence often leads to a lock-in (Arthur 1989) where, given the status quo social norm, there are little individual-level incentives to deviate from the norm. A change in the social norm therefore requires a widespread change of individual expectations regarding the desired behavior. This can occur as a result of political interventions, but also through decentralized processes such as social communication. If the latter occurs, the result often appears on the surface as a relatively sudden tipping from one social norm to another (Young 1998).

Some skepticism is however due with regard to the likelihood of efficient, deliberate changes of both informal social norms and formal laws through the political process. Path dependence in opinion-formation can lead to equilibria where publicly voiced political opinions, which are deemed false by a large majority of individuals, nevertheless dominate political discourse (Kuran 1995). Similarly, a majority of individuals can be easily locked-in believing factually false policy-related beliefs to be true and refusing to update them (Schnellenbach 2004). The fact that policy-making rests not on individual but shared beliefs

(Denzau and North 1994; Bischoff and Siemers 2013), with very limited incentives for individuals to invest into holding factually correct beliefs, is therefore one factor that leads to a frequently observed persistence of inefficient rules.

The evolution of the rules that govern society is therefore to be understood as an interdependent process where informal institutions affect the evolution of formal institutions and vice versa (North 2005). In order to overcome inefficient lock-ins, a careful institutional policy-making is necessary, although not always sufficient (Eggertsson 2005).

Piracy, Modern Maritime

Paul Hallwood and Thomas J. Miceli
Department of Economics, University of
Connecticut, Storrs, CT, USA

Abstract

This entry provides an economic analysis of the problem of modern-day maritime piracy by first reviewing the current scope of the problem and then developing an economic model of piracy that emphasizes the strategic interaction between the efforts of pirates to locate potential targets and shippers to avoid contact. The model provides the basis for deriving an optimal enforcement policy, which is then compared to actual enforcement efforts that, for a variety of reasons, have largely been ineffectual. The entry concludes by reviewing the law of maritime piracy and by offering some proposals for improving enforcement.

Synonyms

Hijacking; Looting; Robbery

Definition

An act of robbery or criminal violence committed at sea.

This entry develops an economic approach to the problem of modern-day maritime piracy with the goal of assessing the effectiveness of remedies aimed at reducing the incidence of piracy. To date, these efforts have been largely ineffectual for several reasons, including gaps in domestic laws, reluctance of countries to bear the expense of imprisoning pirates, and the general lack of an

effective international legal framework for coordinating and carrying out enforcement efforts. Indeed, it is the absence of such a framework that bedevils international public law as a whole, not just in the area of maritime piracy.

The theoretical framework is based on a standard Becker-type model of law enforcement (Becker 1968; Polinsky and Shavell 2000), extended to consider the effort level of pirates to locate and attack target vessels and of shippers to invest in precautions to avoid contact. The model provides the basis for prescribing an optimal enforcement policy whose goal is to minimize the cost of piracy to international shipping. It also serves as a benchmark for evaluating actual enforcement efforts within the context of international law (such as it exists). The entry concludes with several proposals aimed at improving enforcement.

Modern-Day Maritime Piracy

Modern-day maritime piracy is a worldwide phenomenon. Over 2,600 attacks, actual or attempted, were reported over the period 2004–2011, but with some recent decline due to the effort of naval task forces as well as a very large increase in the use of onboard armed guards. For example, the most recent data shows that in the first 11 months of 2013, there were 234 boardings worldwide, with 30 in Nigerian waters and 13 in Somali waters. Many incidents have also been reported in Southeast Asia, especially off Indonesia.

Somali pirates principally operate a capture-to-ransom model, with ransoms of up to \$5.5 million per incident being collected. Elsewhere in the world, robbery is the main motive. The overall economic cost of maritime piracy in 2012 was estimated at \$6 billion, down from \$7 billion the year before and as much as \$16 billion a few years earlier. Spending on onboard security equipment and armed guards increased from about \$1 billion to \$2 billion between 2011 and 2012. Other economic costs include additional travel days as a consequence of rerouting of ships; increased insurance costs of as much as \$20,000 per trip; increased charter rates, as longer time at sea

reduces the availability of tankers; cost of faster steaming through pirate-affected seas; and greater inventory financing costs for cargoes that remain longer at sea (Bowden 2010). Also, according to, an additional 10 attacks are associated with an 11% decrease in exports between Asia and Europe at an estimated cost of \$28 billion.

With regard to antipiracy efforts, Anderson (1995) notes that there are economies of scale in this activity. When trade on a given shipping route is sparse, individual merchant ships have to arm themselves, thereby duplicating investment. However, with greater amounts of trade, several shipping companies may reduce costs by hiring armed ships for their protection as they sail in convoy. And with still greater shipping traffic, the least cost protection method has turned out to be patrolling of large areas of ocean space by warships. Today all three methods are used.

Not surprisingly, the efficiency of the pirate organization contributes to its success, both historically and in modern times (Leeson 2007; Psarros et al. 2011). Accordingly, present-day Somali pirates have developed supportive “social” organizations that aid them on land and at sea (Bahadur 2011). Pirate leaders often require new recruits to swear allegiance to the organization and its leaders until death; many Somali pirates are ex-coast guardsmen or ex-militiamen and share a common background and training; there is a common belief that ransoms are like a tax on foreigners who are overfishing Somali waters; and there is even the use of stock exchanges to finance operations.

An Economic Model of Piracy

This section develops a simple model of maritime piracy that focuses on its harmful effects on shipping (Guha and Guha 2010; Hallwood and Miceli 2013). The model accounts for both the efforts of pirates to locate potential target ships and of shippers to avoid contact with pirates. In this sense, the model extends the standard economic model of crime to account for precautionary behavior of potential victims (Shavell 1991; Hylton 1996).

After deriving the equilibrium of the model, we examine optimal enforcement policies.

The model focuses on a representative pirate and a representative shipper who traverse the same geographic area over a fixed period of time. The pirate devotes effort x (measured in dollars) to locate a target vessel, and the shipper invests precaution y (also in dollars) to avoid contact. The pirate’s effort represents the amount of time at sea and/or the number of boats, while shipper’s avoidance can represent the use of alternate (more expensive) routes, less frequent or fewer voyages, or the use of armed escorts. Let $q(x, y)$ denote the probability of a contact over a given time period, where $q_x > 0$, $q_{xx} < 0$, $q_y < 0$, and $q_{yy} > 0$. Thus, pirate effort increases the chances of an encounter, while shipper precaution reduces the chances, both at decreasing rates. The cross partial q_{xy} may be positive or negative, as discussed in more detail below. (A common formulation is $q(x, y) = x/(x + y)$.)

The benefit to the pirate from an encounter is the loot, which can take the form of confiscated cargo, ransom of passengers, or both. Let G be the gross expected gain from an encounter. The net gain, however, must account for the possibility of capture and punishment. Let p be the probability of capture and s the (dollar) sanction upon conviction, both of which the pirate takes as given. Thus, the net gain per encounter is $G - ps$, which we will assume is positive. (This will necessarily be true if $G > \bar{s}$, where $\bar{s}$ is the maximal sanction. We discuss the nature of s in greater detail in the section on enforcement below.) At the time it makes its choice of effort, the pirate’s expected gain is therefore

$$q(x, y)(G - ps) - x. \quad (1)$$

The pirate chooses x to maximize this expression, taking as given y , p , and s . The resulting first-order condition is

$$q_x(G - ps) - 1 = 0, \quad (2)$$

which defines the pirate’s reaction function, $\hat{x}(y, ps)$.

The shipper expects to earn gross profit of π , which will be reduced by any expected costs associated with the threat of piracy. These costs include the losses inflicted directly by the pirate, denoted h (including the loss of cargo as well as damage to the ship and harm to crew members), plus the cost of avoidance actions, y . The net expected return to the shipper is therefore

$$\pi - q(x, y)h - y. \quad (3)$$

The shipper chooses y to maximize Eq. 3, taking x as given. This yields the first-order condition

$$q_y h + 1 = 0, \quad (4)$$

which defines the shipper's reaction function, $\hat{y}(x)$.

The Nash equilibrium occurs at the point where the reaction functions intersect. Differentiating Eq. 2 yields the slope of the pirate's reaction function

$$\frac{\partial \hat{x}}{\partial y} = \frac{-q_{xy}}{q_{xx}}, \quad (5)$$

which has the sign of q_{xy} given $q_{xx} < 0$, while differentiating Eq. 4 yields the slope of the shipper's reaction function

$$\frac{\partial \hat{y}}{\partial x} = \frac{-q_{xy}}{q_{yy}}, \quad (6)$$

which has the opposite sign of q_{xy} given $q_{yy} > 0$. The equilibrium, which we assume exists and is unique, is shown graphically in Fig. 1.

The Impact of Antipiracy Laws

Enforcement laws against piracy involve efforts to capture and punish pirates. Below we discuss the implementation of these laws in practice; here we examine their impact in theory, given the preceding equilibrium.

Law enforcement directly affects the behavior of pirates through the expected punishment term, ps , while it indirectly affects shipper behavior through their response to the resulting change in pirate behavior. Consider first the effect of changes in ps on the behavior of pirates. (Note that, given risk neutrality, it does not matter whether this is due to a change in p , s , or both.) Differentiating Eq. 2 yields

$$\frac{\partial \hat{x}}{\partial ps} = \frac{q_x}{q_{xx}(G - ps)} < 0, \quad (7)$$

given $G - ps > 0$. Thus, an increase in the expected sanction for piracy reduces the pirate's investment in effort for any y . In Fig. 1, this results in a leftward shift of the pirate's reaction curve. The new equilibrium involves an unambiguous reduction in the pirate's equilibrium level of

Piracy, Modern Maritime,

Fig. 1 Equilibrium choices of pirate effort (x) and shipper avoidance (y)

effort, but the effect on the shipper's investment in avoidance is ambiguous. As drawn, $\hat{y}$ goes up, but it should be apparent that it could also go down, depending on the location of the initial equilibrium and the amount that the pirate's reaction function shifts. The intuitive reason for these effects is as follows.

The negative effect of greater enforcement on the pirate's effort reflects the standard deterrence argument – a higher expected sanction lowers the marginal benefit of criminal activity. The ambiguous effect of enforcement on the shipper's precaution hinges on the sign of q_{xy} . For the case shown in Fig. 1, $q_{xy} > 0$, so as the pirate's effort declines, the marginal benefit of shipper precaution increases (i.e., q_y becomes more negative), causing an increase in y . In this case, enforcement of laws against piracy and shipper precaution are complementary. However, the reverse would be true if $q_{xy} < 0$, for in that case, greater law enforcement efforts, by lowering x , would substitute for, or “crowd out,” shipper precaution. The actual outcome is therefore an empirical question.

Given the preceding effects of increased enforcement, we now turn to the derivation of the optimal enforcement policy, which involves the enforcement authority (whoever that may be) choosing the probability of apprehension, p , and the sanction, s , to maximize social welfare. An important question here concerns whether or not to count the pirate's gains as part of welfare. The convention in the economics of crime literature has been to count the offender's gains, but there are differing views on this issue (Polinsky and Shavell 2000, p. 48). In the case of pure theft, the value of the loot is simply a transfer payment and thus would drop out of welfare if the thief's gains are counted (Shavell 1991). However, if the gains and losses differ, the possibility arises that the transfer could actually be value enhancing – an “efficient theft” – which most people would find objectionable, especially in the piracy context. Thus, although we will follow the standard convention and count the pirate's gains in welfare, we will assume that the loss suffered by the shipper exceeds the pirate's gains – that is, $h > G$. Consequently, any act of piracy is necessarily inefficient. This could reflect damages or harm to victims on

top of the simple transfer of wealth, as well as any fear or “pain and suffering” incurred by victims of piracy and their sympathizers.

Based on these considerations, we write social welfare as

$$W = \pi - q(\hat{x}(ps), \hat{y}(ps))(h - G + p\beta s) - \hat{x}(ps) - \hat{y}(ps) - c(p), \quad (8)$$

where $\hat{x}(ps)$ and $\hat{y}(ps)$ are the equilibrium levels of pirate effort and shipper precaution, which depend on ps in the manner described above. The total expected enforcement costs are $c(p) + q(\hat{x}(ps), \hat{y}(ps))p\beta s$, where $c(p)$ is the cost of deploying more ships ($c' > 0$, $c'' \geq 0$) and β is the unit cost of increasing s . The enforcement problem is to choose p and s to maximize Eq. 8, subject to $p \in [0, 1]$ and $s \in [0, \bar{s}]$, where $\bar{s}$ is the maximal sanction. The possible interpretations of $\bar{s}$ are (i) the maximum prison term the offender could serve (e.g., life), (ii) a death sentence, or (iii) the harshest punishment that the country charged with carrying out the punishment is willing to impose (as discussed further below).

We begin by deriving a standard result in the law enforcement literature – namely, that $s^* = \bar{s}$, or the optimal sanction is maximal (Polinsky and Shavell 2000). To see why, suppose that $s < \bar{s}$ and $p > 0$. Now raise s and lower p so as to hold ps fixed. As a result, all of the terms in Eq. 8 that depend on ps remain unaffected, but $c(p)$ falls, thus raising welfare. This proves that $s < \bar{s}$ could not have been optimal. The intuition for this result is that the cost of s is only incurred if a pirate is actually captured, so overall costs are lowered by capturing only a few offenders and punishing them harshly.

With $s^* = \bar{s}$, we differentiate Eq. 8 with respect to p and, after canceling terms using Eqs. 2 and 4, obtain the following first-order condition for p^*

$$\begin{aligned} & -q_x \frac{\partial \hat{x}}{\partial p} (h + p\beta \bar{s}) + q_y \frac{\partial \hat{y}}{\partial p} (G - p\beta \bar{s}) \\ & = c' + q\beta \bar{s}. \end{aligned} \quad (9)$$

The left-hand side is the marginal benefit of increased enforcement, while the right-hand side

is the marginal cost. The first term on the left-hand side, which is positive, is the saved costs (victim harm plus punishment costs) as pirates reduce their efforts in response to an increase in the probability of apprehension. This is the direct gain from deterrence. The second term, which is ambiguous in sign, reflects the uncertain effect of an increase in p on shipper effort. Suppose $\partial \hat{y} / \partial p > 0$ (as is the case in Fig. 1), indicating that shippers increase their precaution in response to greater p (i.e., public enforcement and private precaution are complements). Let us also suppose that the term $(G - p\beta\bar{s})$ is negative, as would be true if pirate gains are not counted in welfare. In that case, the overall term is positive (given $q_y < 0$), thus amplifying the marginal benefit of enforcement. Intuitively, when public enforcement elicits increased private precautions, p should be raised, all else equal to encourage such precaution. Conversely, if $\partial \hat{y} / \partial p < 0$, the case of crowding out, the second term on the left-hand side is negative, which works in the direction of reducing p so as not to overly discourage private precaution by potential victims.

Enforcement Problems

The preceding represents the optimal enforcement policy in an ideal setting where there exists a single enforcement authority (or a unified coalition of enforcers), possessing both the will and the resources to carry out the policies implied by Eq. 9. While this may represent a reasonable assumption in many law enforcement contexts, enforcement of international laws against piracy is undertaken by multiple countries with varying degrees of interest in devoting resources to the effort. As a result, enforcement involves a problem of collective action, which may lead to several departures from the prescribed policy.

First, the gains from deterring piracy are enjoyed by all countries who make use of the shipping lanes threatened by pirate attacks. Thus, each country has an interest in reducing piracy in proportion to its expected losses. At the same time, however, deterrence of pirate attacks is a public good in the sense that actions by any one country

to invest in enforcement will benefit all countries. Thus, each country has an incentive to free ride on the enforcement effort of others. Absent some form of credible commitment, therefore, those countries with the largest stake (e.g., the highest value of shipping in the affected area) will undertake the bulk of the enforcement, and all other countries will free ride on that effort. Actual enforcement will therefore be less than the efficient level.

A second factor discouraging enforcement efforts concerns the expected cost of imposing punishment once a pirate is apprehended. If this cost is borne entirely by the country that first apprehends the pirate, then enforcers will likely underinvest in an effort to reduce their probability of incurring that cost. This represents a kind of “reverse rent-seeking” problem in which individual countries underinvest in order to lower the chances that they will be the first to catch the pirate. Note that both of the above problems, which arise from the collective nature of enforcement of piracy laws, will arise in any law enforcement context involving overlapping or undefined jurisdictional boundaries. For example, similar problems plague the enforcement of laws against international drug trafficking (Naranjo 2010) and prosecution of the global war on terror.

A third enforcement problem concerns the credibility of threats to actually impose any punishment at all on a band of pirates once they are captured. Since the pirates’ harmful acts are sunk by the time they are apprehended, enforcers may lack adequate incentives to incur the high costs of detention, trial, and final punishment. Although there may be incapacitative benefits of detention, the probability of any particular pirate committing further harmful acts is small compared to the high cost of punishment. As a result, it may be optimal (in a time-consistent sense) simply to release him. This issue is largely ignored in the economics of crime literature, where it is generally assumed that threats to prosecute and punish criminals are taken as given. The issue is amplified in the piracy context because of the absence of a well-established international tribunal that can develop a reputation over time for carrying out threatened sanctions.

A final problem concerns the choice of the sanction s . As the model showed, the optimal

sanction is maximal, but countries may interpret this prescription differently based on constitutional or other considerations, or they may set *s* based on criteria that differ from that described above (which, if they sympathize with the pirates, could involve setting no punishment at all). As a result, pirates will not be able to predict with any accuracy the actual penalty upon conviction, thereby diluting the deterrent effect of greater enforcement. Countries may also differ in their criminal procedures and evidentiary standards. Although countries can theoretically agree by treaty to uniform standards on these matters, philosophical differences regarding appropriate measures (e.g., based on disagreements over the appropriateness of the death penalty or sympathies for pirates) will make this difficult in practice.

International Law Governing Maritime Piracy

This section evaluates the efficacy of international law in light of the preceding analysis. Piracy is a crime under customary international law and is codified as such in the United Nations *Convention on the Law of the Sea* (UNCLOS) (ratified in 1994). Under this *Convention* states parties agreed to “cooperate” in policing the oceans outside of territorial waters and to arrest, prosecute, and imprison persons suspected and ultimately found guilty of piracy (Articles 100–107). In fact, these articles were taken verbatim from Articles 14–21 of the *Convention on the High Seas*, which was put into force in 1962.

The evidence on actual enforcement of international laws against maritime piracy, as defined by UNCLOS, suggests that these laws have largely been ineffective. For example, over the period between August 2008 and September 2009, Combined Task Force 151 and other navies in the Horn of Africa region disarmed and released 343 pirates, while only 212 others were handed over for prosecution (Ungoed-Thomas and Woolf 2009). The UN Security Council likewise reports that 90% of apprehended Somali pirates were released (UN Security Council 2011).

The discussion in the previous section suggests why this is the case: policing and enforcement is

a public good or at least a mixed good with external benefits for third parties. There are, however, some other considerations as well. The first simply concerns those acts that meet the definition of piracy under the *Convention*. Acts must be for “private ends,” suggesting that they must be motivated by the desire for material gain rather than for political purposes. Thus, terrorist acts would not meet the definition of piracy (Bendall 2010, p. 182) nor would hijacking or acts involving “internal seizure” of a ship by its crew or passengers (mutiny) under the so-called two-vessel requirement for piracy (Hong and Ng 2010, pp. 54–55).

A second difficulty, as discussed above, is the overlapping jurisdiction problem. UNCLOS only applies to acts of piracy on the high seas and in the 200-mile exclusive economic zones, and enforcement relies on the cooperation of all member states. Enforcement in the 12-mile territorial waters is the responsibility of the coastal state, and states vary both in their definitions of piracy and in the availability of resources or the will to enforce anti-piracy laws (Hong and Ng 2010, p. 55; Dutton 2010). Pirates will therefore naturally gravitate toward those areas where enforcement efforts are low or where antipiracy laws are weak. Of course, shippers will also avoid those areas (though at a cost of rerouting), so states with weak laws will suffer economic costs. However, because shipping lanes inevitably cross jurisdictional boundaries, some of those costs will be externalized.

A third problem with enforcement of international law, mentioned earlier, is the problem of successfully prosecuting those pirates who have been apprehended. Article 105 permits the apprehending state to prosecute offenders, but this has often been difficult both politically and logistically. For example, Fawcett (2010) notes that problems of transporting defendants and evidence gathering are significant impediments.

However, in Southeast Asia there has been some success in cooperation against piracy under the *Regional Cooperation Agreement on Combating Piracy and Armed Robbery against Ships in Asia*, which has been functioning since 2006 and now has 17 contracting parties (Noakes 2009). Under this agreement, the parties share

information and perform antipiracy patrols, especially in the Straits of Malacca. What may have helped in this instance is that in this region, there is relatively little area of high seas (none in the Straits of Malacca), and so policing is largely restricted to waters over which sovereign rights exist. As a result, the benefits of enforcement against piracy are more concentrated on the enforcing country, and hence there is less of a public good problem.

Proposals to Improve Enforcement

This section offers three proposals to improve the enforcement of antipiracy laws. The first, suggested by Dutton (2010), involves putting suspected pirates on trial in the International Criminal Court (ICC) rather than in the national court of the apprehending party. The ICC was created by the Rome Statute, which was ratified in 2002 and has 110 signatories, all of whom share in its costs according to an agreed-upon formula (Romano and Ingadottir 2000). However, while the Rome Statute grants the ICC jurisdiction over war crimes, crimes against humanity, genocide, and aggression, at present the ICC has jurisdiction only over the first three of these and that it will not be until 2017 that it can exercise jurisdiction over the crime of “aggression,” which still has to be defined in law but under which piracy could conceivably be classified. Another difficulty with using the ICC against piracy is that some signatories may decline to finance the court for this purpose; that is, a states party choosing to free ride under UNCLOS may also wish to do so under a revised Rome Statute.

The second proposal involves extending the *Convention for the Suppression of Unlawful Acts against the Safety of Maritime Navigation* (SUA Convention) to piracy as well as to terrorism. The SUA came into force in 1992 and by 2011 it had 156 signatories and ratifications. This *Convention* is targeted at policing the oceans against criminal activities, though it specifically targets terrorism rather than piracy. The word “terrorism” appears five times in SUA, but the term is never defined, leading some to believe that, with appropriate reinterpretation,

SUA could be used against maritime pirates (Hong and Ng 2010).

Cognizant of these features Noakes (2009), the chief maritime security officer for the Baltic and International Maritime Council (BIMCO) argued before a US House of Representatives Committee that SUA 1988 can and should be used to combat piracy and that it is incorrect to view this *Convention* as applying only to maritime terrorism and not maritime piracy. It is certainly true that SUA 1988 uses the word “terrorism” sparingly, and this could give the impression that it could be used in the context of maritime piracy. However, SUA 1988 grew out of UN General Assembly Resolution 40/61 in 1985, itself being a response to terrorism on the *Achille Lauro*, and Resolution 40/61 is clearly aimed at terrorist acts at sea and not piracy.

Still, Article 3 of SUA defines seven offenses, the first three being described as follows:

Any person commits an offence if that person unlawfully and intentionally: seizes or exercises control over a ship by force or threat thereof or any other form of intimidation; performs an act of violence against a person on board a ship if that act is likely to endanger the safe navigation of that ship; or destroys a ship or causes damage to a ship or to its cargo which is likely to endanger the safe navigation of that ship.

Although an authoritative legal opinion by each signatory states party regarding exactly what crimes at sea the SUA encompasses has yet to be given, the US legislative attorney, R. C. Mason, working for the Congressional Research Service, has suggested, based on Article 3, that the SUA is directed at piracy as well as terrorism at sea (Ploch et al. 2010). However, this is only “guidance” and at present the US position on SUA and piracy remains unresolved.

Kilpatrick (2011) offers a third proposal, arguing that the UN Hague Convention (1970) could be extended from international civil aviation to maritime piracy. This Convention has been widely adopted, with 185 signatories as of 2013, and it compels states to either extradite or prosecute airplane hijackers. It also requires signatory states to punish terrorist acts by “severe penalties” through domestic laws. However, it is questionable that countries will move to extend the Hague

Convention to maritime piracy. This is true for several reasons. First, while the United States is of central importance in global civil aviation, it is much less so in international shipping. In civil aviation, US legislation has a significant impact on global regulation because foreign airlines and flights from foreign airports to the United States that do not meet US security standards are effectively prohibited from accessing its lucrative market. Second, countries are probably more strongly motivated to move against aircraft hijackings because each single incident is likely to affect more people, say, 250 persons on an airplane versus 20 or so on a ship. Finally, aircraft hijackings seem to be given much more prominence in the media than maritime hijackings.

Piracy, Old Maritime

Peter T. Leeson
Department of Economics, George Mason
University, Fairfax, VA, USA

Abstract

Eighteenth-century pirates were profit-maximizing criminals. Their infamous practices reflect strategies pirates adopted to bolster their bottom line. The “pirate code” was a system of constitutional democracy that sea

dogs developed to govern themselves privately in the absence of government. The “Jolly Roger” – pirates’ black flag of skull and bones – was a signaling device that sea dogs used to facilitate the seizure of prizes without costly conflict. Pirates used heinous torture to develop a reputation that incentivized captives to acquiesce to their demands. And pirates “pressed” – or pretended to conscript – willing recruits to reduce sailors’ legal cost of joining their crews.

Synonyms

Caribbean piracy; Eighteenth-century piracy; Golden Age piracy

Definition

Old maritime piracy refers to the seafaring banditry of early eighteenth-century (c. 1715–1730) criminals. These pirates preyed on merchant ships traveling through the Atlantic Ocean, Indian Ocean, Caribbean Sea, and Gulf of Mexico. The pirate population – at its height, an estimated 2,400 sailors (Rediker 1987, p. 256) – was drawn predominantly from the merchant marine, consisting mostly of ordinary seamen who voluntarily joined a pirate crew’s ranks after the vessel they were sailing on had been seized by its attackers. Old maritime piracy’s most infamous members included Blackbeard (real name, Edward Teach), Bartholomew Roberts, “Calico Jack” Rackham, and at least a few women, such as Rackham’s crewmates, Anne Bonny and Mary Read.

Pirates lived and worked together at sea and on land. When “on the account” – sea dogs’ term for pirating – they operated in independent crews averaging 80 members (Rediker 1987, p. 256). When not at sea, many pirates made homes in New Providence Island, Bahamas – a neglected and thus rogue-infested British colony. Unlike privateers, who were also active in the early eighteenth century and plundered merchant ships for profit, pirates paid allegiance to no government

and lacked the sanction or support of any state. Pirates were considered, and considered themselves, “enemies of all nations.”

The Decision to Pirate

During peacetime, when privateering employment was unavailable and naval employment was difficult to find, most sailors had two employment choices. One possibility was to work in the merchant marine. The pay in this employment was low. Between 1689 and 1740 the average able seaman earned between £15 and £33 a year (Davis 1962, pp. 136–137) – \$4,000–8,800 in current US dollars.

Sailors’ second occupational option was piracy. Piracy was a capital offense throughout eighteenth-century Europe, and pirating was a risky activity. Nevertheless, the potential financial rewards of pirating were sufficient to attract an estimated 4,000 sailors to illicit maritime plunder between 1716 and 1726 (Rediker 1987, p. 30). No data exist that would permit a computation of the average pirate’s wage. However, the evidence that is available suggests that piracy, unlike work as an able seaman, could be extremely lucrative.

In the early eighteenth century, Captain John Bowen’s pirate crew plundered a prize that resulted in a payout of £500 per man (Johnson 1726–1728, p. 480). Several years later the members of Captain Thomas White’s crew each earned £1,200 from its cruise (Johnson 1726–1728, p. 485). In 1720 Captain Christopher Condent’s crew seized a prize that earned each pirate £3,000 (Marx 1996, p. 161). And in 1721 Captain John Taylor’s and Oliver La Bouche’s pirate consort earned an astonishing £4,000 for each crewmember in a single attack (Marx 1996, p. 163). Although more modest prizes were more common, a successful expedition could yield a pirate a sum sufficient to retire. The prospect of immense financial reward that piracy offered was an important lure for sailors who left merchant-marine employment for risky careers as pirates.

A second, and perhaps equally important, consideration for many sailors who chose piracy over

legitimate maritime employment was the work and living conditions available on pirate ships versus those available on merchant ships. For reasons described below, captain mistreatment of ordinary sailors on merchant vessels – financial and physical – was a relatively common feature of merchant-marine employment. In contrast, on pirate ships officer abuse was far less common, rendering life aboard such vessels superior in many sailors' eyes.

Pirates' Profit-Maximizing Strategies

Organization

As criminals, pirates could not rely on state-made institutions of law and order to produce social cooperation among them. Yet to live and work together at sea for months at a time – i.e., for pirating, a necessarily jointly produced activity, to be possible at all – piratical cooperation was essential. Indeed, as persons committed to theft and murder for personal gain, the need for institutions of social order among pirates was likely more pronounced than it was among the members of legitimate societies, most of whom, in contrast to pirates, were not so willing to resort to violence to benefit themselves.

The success many pirate crews enjoyed suggests that pirates overcame the problem of social cooperation they confronted without government. Central to the way pirates accomplished this was their institutional organization grounded in constitutional democracy (Leeson 2007, 2009a). Two chief officers led early eighteenth-century pirate ships – the captain and the quartermaster. The former wielded command in times of battle, when chasing and engaging prey. The latter wielded command at all other times: the quartermaster was in charge of distributing crewmembers' victuals and payment and enforcing pirates' private laws. Pirate crews elected both officers democratically and deposed their officers popularly too.

Pirates' democratic selection of officers contrasts starkly with the selection of officers on early eighteenth-century merchant ships and naval vessels, who were appointed by owners and

governments externally. Likewise, the division of power on pirate ships via the captain and quartermaster contrasts starkly with the centralization of power on period merchant and navy ships, where captains wielded autocratic authority over their crews. Pirates' institutional organization also differed sharply from that of early eighteenth-century European states, whose autocratic forms closely resembled those of legitimate, period sea vessels.

Pirates created their own social rules to prevent conflict and maximize the potential for piratical cooperation, which in turn maximized their crews' illicit profits. Pirates developed a body of private law, sometimes called the "pirate code," but which pirates called "articles of agreement" (Leeson 2009c). Each crew forged its own articles democratically and required the consent of every would-be member to its provisions before he was permitted to join the company.

The specifics of pirate articles differed by crew, but their basic elements were uniform. These included rules prohibiting theft and violence; terms governing crewmembers' compensation; regulations on activities that could generate negative externalities for other crewmembers, such as drinking and smoking; and terms of piratical social insurance, which was provided for crewmembers injured on the job. Pirate articles also established punishments for article violations and provided explicitly for democracy as the governing mechanism for important crew decisions, such as the selection of officers.

Remarkably, pirates enshrined their articles in writing as constitutions. Below is the constitution that governed pirate captain Bartholomew Roberts' crew aboard their ship the *Royal Fortune* (Johnson 1726–1728, pp. 211–212):

- (I) Every Man has a Vote in the Affairs of Moment; has equal Title to the fresh Provisions, or strong Liquors, at any Time seized, and may use them at Pleasure, unless a Scarcity make it necessary, for the Good of all, to vote a Retrenchment.
- (II) Every Man to be called fairly in Turn, by List, on board of Prizes, because, (over and above their proper Share) they were

on these Occasions allowed a Shift of Cloaths: But if they defrauded the Company to the Value of a Dollar, in Plate, Jewels, or Money, Marooning was their Punishment. If the Robbery was only betwixt one another, they contented themselves with slitting the Ears and Nose of him that was Guilty, and set him on Shore, not in an uninhabited Place, but somewhere, where he was sure to encounter Hardships.

- (III) No person to Game at Cards or Dice for Money.
- (IV) The Lights and Candles to be put out at eight a-Clock at Night: If any of the Crew, after that Hour, still remained enclined for Drinking, they were to do it on the open Deck.
- (V) To keep their Piece, Pistols, and Cutlash clean, and fit for Service.
- (VI) No Boy or Woman to be allowed amongst them. If any Man were found seducing any of the latter Sex, and carry'd her to Sea, disguised, he was to suffer Death.
- (VII) To Desert the Ship, or their Quarters in Battle, was punished with Death or Marooning.
- (VIII) No striking one another on board, but every Man's Quarrels to be ended on Shore, at Sword and Pistol.
- (IX) No Man to talk of breaking up their Way of Living, till each shared a 1,000 l. If in order to this, any Man should lose a Limb, or become a Cripple in their Service, he was to have 800 Dollars, out of the publick Stock, and for lesser Hurts, proportionately.
- (X) The Captain and Quarter-Master to receive two Shares of a Prize; the Master, Boatswain, and Gunner, one Share and a half, and other Officers one and a Quarter.
- (XI) The Musicians to have Rest on the Sabbath Day, but the other 6 Days and Nights, none without special Favour.

Constitutional democracy among pirates pre-dates its adoption in the United States by more

than half a century. Equally surprising, pirates' reason for relying on this system of governance echoes the reason given in the *Federalist Papers* – or rather the other way around, since the Federalists did not put pen to paper until decades after pirates put constitutional democracy into practice. According to pirates, their reason for using constitutional democracy was to prevent their officers from abusing the authority that officers' positions of power necessarily conferred on them. Guarding against such abuse was particularly important to pirates, they suggested, given the mistreatment they had suffered in their previous lives as legitimate sailors at the hands of merchant captains who enjoyed near-dictatorial authority over their crews.

Pirate democracy permitted crewmembers to control the behavior of captains through the carrot of election and the stick of deposition. Moreover, the creation of multiple, popularly elected offices aboard pirate ships fostered competition between officers, which encouraged both captains and quartermasters to more faithfully adhere to the will of their crews. Circumscribing officers' authorities in written constitutions helped pirates ensure that their leaders wielded the powers they enjoyed in their crews' interests rather than for leaders' private gain. By making behaviors that constituted transgressions of those authorities explicit and requiring that all crewmembers consent to their terms *ex ante*, pirate constitutions created common knowledge about legitimate and illegitimate officer behaviors within pirate crews and helped coordinate pirates' response to officer behaviors.

The contrasting institutional organization of eighteenth-century pirate ships and merchant ships has an economic foundation (Leeson 2007). Merchant ships confronted a classic owner-employee, principal-agent problem. These vessels and their cargoes were financed by external financiers – wealthy landlubbers who funded commercial voyages. Since merchant-ship owners did not sail on the vessels they invested in, their valuable vessels and cargoes were beyond their eyes or reach when away at sea.

This situation invited sailor opportunism, such as stealing cargo, shirking in work activities, or

even absconding with vessels. To control such opportunism, merchant-ship owners appointed captains who they gave small shares in their ships and endowed with autocratic authority to monitor and financially and physically punish sailors who did not act in their interests. Autocratic captains solved owners' principal-agent problem. But in doing so they enabled captain self-dealing, which, as merchant sailors frequently complained, many captains exploited at their sailors' expense.

Pirates, in contrast, confronted no such owner-employee, principal-agent problem. The reason for this is simple: pirates stole their ships. On pirate ships, crewmembers were both owners and employees – principals and agents. Because of this, pirates did not require autocratic captains to control crewmember opportunism. They still needed leaders who could command in times of battle and administer rules that prevented crewmember conflicts. But in the absence of a divergence between principal and agent interests, pirates could democratically elect their leaders and divide authorities among them without loss, and indeed with substantial benefit: restraining the potential for captain self-dealing. The economic context of eighteenth-century merchant shipping rendered autocracy the efficient institutional organization on merchant ships. The different economic context of eighteenth-century pirating rendered constitutional democracy the efficient institutional organization on pirate ships.

Other Profit-Maximizing Strategies

Pirates employed several other practices to maximize the profitability of their criminal enterprise. Each of these practices is an infamous part of popular pirate lore. One example of this is pirates' black flag of skull and bones, the "Jolly Roger," which pirates used as a signaling device to distinguish themselves from less ominous maritime belligerents who merchant ships might confront and whose advances merchant ships were more likely to resist (Leeson 2009a). A second example is pirates' use of heinous torture against recalcitrant captives and their popular image among contemporaries as fiendish "hair-triggers," both products of pirates' manipulation of their public

image, which pirates used to develop a reputation that encouraged prizes to surrender to them peacefully (Leeson 2010a). A third example is pirates' practice of "pressing" – or pretending to compel crewmembers into their service – a practice pirates used to manipulate laws against piracy that reduced merchant sailors' expected cost of joining pirates' ranks (Leeson 2009b, 2010b).

Political Competition

Anna Laura Baraldi

Department of Economics, Second University of Naples, Capua, Italy

Abstract

In this entry, we tried to explain the role of political competition in the economy. Political science provided various definitions of

political competition. After analyzing in detail all of those, we mentioned the actors political competition involves. In economic terms, competition in political market has seen as competition in good market. Therefore, economic science studied if this kind of competition is good or bad in terms of economic variables as, for example, growth.

Party competition: definitions, sources, and economic effects

Political Competition: Definitions, Sources, and Economic Effects

Political competition is a complex process at the heart of representative democracy. *It* can be defined as competition for political power, that is, for the right to shape and control the content and direction of public policy.

Broadly speaking, this process involves the interaction of a set of *citizens*, each one with views about the relative desirability of conceivable states of the world; a set of *constitutional rules*; a group of *politicians* who compete in the selection for constitutionally privileged positions within the decision-making process; *political parties* who choose to coordinate their behavior that they see as mutually beneficial; a group of *political representatives* in charge of representing citizens in the decision-making process; a group of *office-holders*, politicians selected under constitutional rules to hold privileged positions in the decision-making process; and a *government*, defined as a unique coalition of office-holders in the most privileged positions in the decision-making process.

The unequal distribution of benefits and costs of living among different individuals and groups is the primary source of political competition in a society. Indeed, the decisions and actions of governments benefit, reward, and advantage only certain areas of the society, while others are compelled to bear more of the costs and burdens.

Therefore, political competition is the continuing controversy over who controls the government and who officially decides how its formal-legal power is to be used.

Under a free and competitive, constitutional democratic political regime, different groups and organizations within the society engage in political competition. This can be for political authority and for political influence.

Competing for political authority means contending for the legitimate right to govern the entire political community (as carried out by the Labour and Conservative Parties in Britain, the Democrats and Republicans in the United States, and the Liberal and Progressive Conservative Parties in Canada); they compete for direct control of the government and for the legitimate right to officially decide how and for what purposes governmental authority is to be used. Each political party seeks to place its own political leaders in the majority of the government, thereby giving them the right to decide for and act in the name of the entire political society, exercising formal-legal authority to make and enforce authoritative, and binding decisions on public policy. The individual candidate, by seeking his/her party's nomination and then election by the voters to a higher government office (such as member of the legislature), is competing for the right to be a formal-legal participant in the processes of authoritative decision-making and action carried out by the government.

Competition for political influence means that *political interest groups* or *pressure groups*, whose members have common interests and views in a single area of public policy, seek to obtain and exercise political influence therein. Their objective is to influence the policy decisions and actions of the government in one or more areas of public policy. An interest group focuses on influencing and shaping public policy in their chosen policy area or areas, rather than attempting to have an impact on public policy in general.

Political competition overlaps two disciplines: economics and political science. The concept of political competition has been developed in the literature of political science and is directly related to the outcome of elections. It is commonly

asserted that the more competitive the parties, the more responsive the political system will be to the desires of the majority. Different interpretations of political competition have been given (Bardhan and Yang 2004) in the relevant literature. According to these interpretations, political competition generates costs and benefits. The definitions of political competition are the following:

1. Political competition as *accountability for incumbents*. This interpretation focuses on the process of political turnover. The intensity of political competition increases when the incumbent leaders can be removed more easily by the public and replaced by their competitors. Political competition affects the behavior of incumbent leaders today via tomorrow's threat of dismissal. The benefits of *accountability for incumbents* are due to the "accountability" of politicians: if the incumbent politician wants to maintain power, their incentive to respond to the public's wishes is stronger when their position is vulnerable. Therefore, more intense political competition makes the incumbent more accountable for his/her actions. This interpretation of political competition also generates costs linked to the strength of the threat of dismissal for the incumbent politician. Actually, when a degree of political competition is too high, the probability of reelection becomes sufficiently unrealistic; thus, the incumbent politician may abandon any hope of reelection in order to extract the maximum rents for himself/herself during his remaining time in office. This then shifts political incentives towards the short term. In an economic sense, this concept of political competition may be an important determinant of corruption of politicians.

Political competition, in the sense of political turnover, may generate another cost. The cost is evaluated in terms of the incumbent politician's incentives to undertake public investments. Although public investments are growth enhancing, they are politically destabilizing: to keep his position secure, the incumbent may decide not to invest, given that investment must be financed by taxes. In this

situation, when political competition is high, the destabilizing effects of public investment weigh more heavily on the incumbent, in many cases leading to a non-investment outcome (Acemoglu and Robinson 2000, 2002).

2. Political competition as *decentralization of political authority*. According to this interpretation, political competition is more intense when political authority is in the hands of a larger number of agents at any given point in time. This kind of political competitiveness has been largely studied in the literature on fiscal federalism. Competition between authorities representing distinct political jurisdictions induces each of them to become more politically efficient. In fact, authorities representing "efficient" political jurisdictions, in terms of limited corruption level or sound economic policy, have the opportunity of attracting mobile resources away from authorities representing inefficient jurisdictions. In these situations, competition between authorities is similar to competition between firms. As in the case for firms, competition between political authorities can generate economic costs whenever externalities are present. The model of fiscal policy is the theoretical framework used to illustrate this point. In this model, decentralized political authorities decide on public spending; they compare the marginal benefits of public spending to only a fraction of the social marginal costs. The reason is that the benefits of public spending are generally concentrated within a particular jurisdiction, or a particular interest group, while the costs are spread out across the whole of society. This leads, in equilibrium, to a depleted pool of public savings (Persson and Tabellini 2000; Drazen 2001).

If we consider the competition in attracting mobile resources, inter-jurisdictional competition may generate potential costs and benefits (Besley and Case 1995). The model considers a multi-jurisdictional framework with heterogeneous elected officials; agents are *immobile*, but they can deduce information about their "types" of local officials by observing the behavior of officials in neighboring

jurisdictions. This leads local officials to be engaged in “yardstick competition,” whereby each recognizes that his performance will be judged in relation to the performance of others. This form of competition can yield benefits to the people because, in order to maximize their probability of reelection, politicians have an incentive to “hide their true colors” (Besley and Case 2003), for example, by restraining taxation. However, this form of competition can also produce costs to the people in situations where this behavior is expected to prove too expensive; politicians may decide to abandon their hope of reelection in order to “seize all they can” from the public then and there.

It is possible that the “market for policy” view is not complete. This can be a result of inter-jurisdictional competition aimed at gaining mobile resources, which are also inclined to distinctive frictions. For example, agreements with coalitions of less mobile constituents are made instead of facing electoral incentives to disregard the intimidations of the mobile (Rodden and Rose-Ackerman (1997)). The distortionary effects can be quite serious when tighter complicity rather than greater numbers are reflected in the political power of the immobile; this is common for oligarchic landed interests.

For a model of the trade-off between local informational advantages of decentralization and the possibility of capture by the local elite, see Bardhan and Mookherjee (2006).

3. Political competition as *electoral competition*. This interpretation of political competitiveness focuses on the conflict between parties and elites to win public support. In this sense, political competition is the competition between essentially identical agents to *acquire* political power or between those already in power. Therefore, it is clearly related to both the first and second interpretations of political competition, which associate political competition with opportunities for political turnover, and decentralization of political authority, respectively.

Now we can highlight some key points characterizing political competition. Firstly, an

increase in political competition (i.e., the number of political parties engaged in electoral competition) can be seen as a sign of the democratization of a society. Secondly, a major part of political literature states that the degree of political competition among political party systems is largely determined by the choice of the electoral system (Cox 1997; Duverger 1954; Lijphart 1994, 1999; Sartori 1976; Taagepera and Shugart 1989). Thirdly, the party system determines the degree of bargaining complexity that may affect government formation and maintenance (De Winter and Dumont 2003; Lijphart 1999; Müller and Strøm 2003; Van Roozendaal 1997) and feature among the determinants of public policy. In this entry, we will also treat political competition from an economic perspective. Since Marshall’s “Principles of Economics” (1890), economists have been trained to believe that market competition maximizes the welfare of the consumers, whereas monopoly and market power create economic rents that make producers better off and consumers worse off. The literature of public choice, followed by political economy scholars, attempted to import this notion into the political market, using economic performance as a benchmark to evaluate the welfare properties of political equilibria (Persson and Tabellini 2000). Stigler (1972) studied analogies between economic and political competition. Political competition, as economic competition, is supposed to be welfare enhancing for the citizens. This is because more vigorous political competition implies the selection of politicians who are better at resisting interest group pressures to obtain transfers financed by distortionary taxation. On the contrary, electoral competition with few parties reduces the degree to which the political system represents the heterogeneous preferences of the electorate (Lipset and Rokkan 1967) and may also reduce the pool of available political talent (Becker 1983). Since modern times, it can be said that political competition enhances economic efficiency and makes a faster income growth possible.

Nevertheless, theoretical literature is not conclusive in stating whether political competition is or is not growth enhancing. In order to analyze how it affects economic performance, such

literature refers to political competition as electoral competition: competition among parties and candidates in elections to obtain public support through votes of citizens (Bardhan and Yang 2004). This concept of political competition seems close to that of accountability for incumbents (Persson et al. 1997): if political competition is intense, the incumbent politician is more accountable for he/she actions in office and he has an incentive to perform well; otherwise, he can be easily removed by the public and replaced with opponents.

If the votes market is considered as a goods market (with politicians competing with each other to win the elections – Becker 1983), the transmission mechanism linking political competition to growth implies that more intense political competition induces incumbent politicians to act in the public interest, maximizing their probability of being reelected (Mulligan and Tsui 2006). Otherwise, when political competition is intense, the electoral base of each party tends to be smaller. In order to cater to their narrow support base, politicians find it expedient to promise pork-barrel policies rather than policies that benefit the electorate as a whole. The resulting policies benefit the supporters of the winning politician, but do not necessarily maximize aggregate welfare (Lizzeri and Persico 2005).

Public Choice literature concentrates on the effect of political competition on government size, according to two interpretations: the interest group theories (Mueller and Murrell 1986) and the fiscal illusion view (Buchanan and Wagner 1977), both assessing a negative relation between political competition and government size. Lipford and Yandle (1990), taking an industrial organization view of the political market, find that the state share of total state and local tax revenues rises with party dominance.

A well-consolidated body of the relevant literature analyzes how political competition affects corruption which, in turn, affects economic performance. The theoretical literature in the field of the relationship between corruption and economic growth is split, for example, in the literature on political competition and corruption. Polo (1998) shows that intense political competition may alter

the form of corrupt behavior. Policy distortions resulting from lobbying activities are likely to be greater when there is little electoral competition. However, when politicians use discretion over the way in which political contributions are spent, greater electoral competition increases the incentive to divert funds for personal use (Damania and Yalcin 2005). Persson et al. (1997) state that intense political competition implies that the incumbent politician is more accountable for his actions in office: either the incumbent has an incentive for good performance or he can be easily removed and replaced (Mulligan and Tsui 2006). Intense political competition may also lead to a low probability of reelection for the incumbent, as for a firm that may lose a share of the market if the latter becomes more competitive; in this case, an incumbent can act in a myopic manner, maximizing rents during his remaining time in office. To sum up, the overall effect of political competition on corruption is complex and difficult to define.

The empirical literature on the effects of political competition on economic growth is still poor and lacks in giving a unanimous answer. Recently, the analysis focusing on the different sources of growth (Pinto and Timmons 2005) has made the effect of political competition on growth unpredictable.

Besley et al. (2010), analyzing the relationship between political competition, economic policy, and economic performance in the United States, show that political competition may positively affect policy and economic growth via the “quality of politicians”. Padovano and Ricciuti (2009) analyze the effect of an institutional reform (i.e., the change in the regional electoral system) on the competitiveness of Italian regional politics. They find evidence of a positive correlation among them for the 15 Italian regions with Ordinary Statutes. Alfano and Baraldi (2012) find an inverted U relationship between the degree of political competition and the growth rate; this result shows the possibility that an “optimal” level of political competition, in terms of growth, may exist. This optimal level resolves the trade-off between political accountability and government instability.

The complexity in the empirical literature on that topic is how to measure political competitiveness among political parties, and a number of measures of political competition have been proposed. Vanhanen (2000, 2003) measures competition by the share of votes captured by “minor” parties in parliamentary elections, while Holbrook and Van Dunk (1993) and Rogers and Rogers (2000) use the “win margin” of the incumbent governor as a measure of competition, and Skilling and Zeckhauser (2002) focus on the length of time a party has been in office. Alfano and Baraldi (2012) construct a “political competition index” equal to one minus a (normalized) Herfindahl index for the political parties in a country, taking the percentage of votes for each political party at elections. All these measures have merits, but they often start from the presumption that some basic democratic structures are in place and they are not invariant to the choice of election rule and do not account well for party structure (Vanhanen 2000).

In order to overcome the drawback that measures of political competition have, Grofman and Selb (2009) have recently identified six properties that any index of competition should have:

1. The measure should be party specific, i.e., it should allow for the possibility that voters of different parties might have different incentives to turn out to vote.
2. For each party, the measure should run from 0 to 1, with 0 indicating situations where voter incentives to turn out are the least and 1 indicating situations where voters incentives to turn out are the greatest.
3. The measure should be summable over all parties to give a weighted average of overall incentives for turnout in a given district. This aggregate measure should, when appropriately normalized, still run from 0 to 1, with 0 again indicating situations where, in the aggregate, voter incentives to turn out are the least and 1 indicating situations where, in the aggregate, voter incentives to turn out are the greatest. The weights should reflect the vote shares of the parties, and aggregation to the legislature as a whole should not be distorted by variation in

district population size as a function of district magnitude.

4. For each party, the maximum value should be obtained if the votes required to win its last seat (s) are such that a vote loss of one vote would convert a win for that seat (those seats) into a loss. The minimum value should be obtained if one candidate/party receives all the votes.
5. The measure should be sensitive to the nature of the voting rule being used. We propose that it should vary with the threshold of exclusion of that rule.
6. For two-candidate plurality elections, the measure should be reduced to a simple function of the difference in vote share between the winner and the loser.

To sum up, neither theoretical nor empirical literature clarifies whether an intense political competition is beneficial for economic growth or not. Nevertheless, the tendency of many democracies is to reduce the number of political parties engaged in electoral competition. A lot of electoral systems are set up to counteract the tendency of parties to multiply. Many parliamentary democracies have thresholds of exclusion that deny representation to parties with a vote share below the threshold (e.g., Germany has a threshold of 5%). With a threshold of exclusion, the number of parties is reduced because parties that anticipate a small vote share do not field candidates. The general point is that several features of electoral systems act to discourage the proliferation of parties. The main conjecture in support of that is that having a large number of parties creates government instability, which is thought to harm economic growth. In fact, when there are many competing parties, the electoral base of each party tends to be smaller. To cater to their reduced support base, politicians find it expedient to promise pork-barrel policies with narrow appeal, rather than policies that benefit the electorate at large. The resulting policies benefit the supporters of the winning politician, but do not necessarily maximize aggregate welfare. For instance, politicians must choose between creating a large or small amount of bureaucracy. The former entails an aggregate deadweight loss but generates some

benefits (jobs, etc.) that can be targeted to supporters; the latter, instead, is efficient but does not allow the politician to target largesse to supporters. Consequently, we should expect a large amount of bureaucracy. The idea is that projects which diffuse benefits (the minimum bureaucracy) are less appealing to office-motivated politicians because these benefits are less targetable and so may be under-provided by the political system. This distortion becomes worse as the number of competing parties increases. The reason is that the smaller the fraction of the electorate as the support base of each party, the higher the gain from targeting a smaller subset of the electorate, and therefore, the temptation for politicians to engage in special interest politics becomes greater.

Political Corruption

Roy Cerqueti and Raffaella Coppier
Department of Economics and Law, University of
Macerata, Macerata, Italy

Abstract

Political corruption represents a specific type of public-to-public corruption which implies that one participant of corrupt transaction belongs on the State and the other to the private sector: in fact, public corruption is a particular (and illegal) State-society relationship. Political corruption occurs when politicians, who are delegated to make laws and enforce them by the citizens, act themselves in a corrupt way. More precisely, it appears when policymakers exploit their political strength to pursue their own economic benefits and/or maintain their powerful position.

Introduction

To begin, it is important to define the word “corruption.” According to Jain (2001), “Corruption is an act in which the power of public office is used for personal gain in a manner that contravenes the rules of the game.” Here we are only referring to public-to-public interaction and not private-to-private. While public-to-public corruption usually involves a private party on one side and public official or member of State on the other, private-to-private corruption is any form of illegal transaction between associations or corporations

within the private sector. When, for example, a director or employee gets involved in practices that are not part of his responsibilities and that are detrimental to the company he is working for but advantageous for himself or others, this can be defined as private-to-private corruption: “the type of corruption that occurs when a manager or employee exercises a certain power or influence over the performance of a function, task, or responsibility within a private organization or corporation” (Argandoña 2003).

For many years different political scientists have approached the subject of political corruption and the difficulty in defining the term. In some cases, certain practices may be considered legal (e.g., certain forms of bribery), consequently making corruption appear less prevalent or occasionally also having the adverse effect (Olken and Pande 2012). After Peters and Welch (1978) explained that “the systematic study of corruption is hampered by the lack of an adequate definition” and “What may be ‘corrupt’ to one citizen, scholars, or public official is ‘just politics’ to another, or ‘indiscretion’ to a third,” many have tried to come up with different ways of solving the problem.

As we can deduct from Jain’s definition, corruption usually stems from three different circumstances – weak institutions, discretionary power, and economic rents.

Firstly, regarding weak institutions, the rewards gained from corruption will always have to be more significant than the foreseen payoff from the process of being discovered and punished. Secondly, for corruption to occur, the State member in question must be able to control the designation of resources in a discretionary manner. Lastly, it must be possible to extract rents or create extractable rents on behalf of the discretionary power.

Therefore with regard to public-to-public corruption, as mentioned above, there are two sides – the State (politicians, bureaucrats, civil servants, officials, and anyone who has discretionary power over society) and the private party. When politicians (or any State members) take advantage of their position to unlawfully obtain resources to their advantage (or in favor of others), this is

considered to be a corrupt practice which is carried out on the boundary between public and private environments.

Business and financial corruption which are widespread and indeed any transactions which happen exclusively in the private environment, away from the public sector, will not be considered in this voice.

It is worth identifying what actually constitutes corruption. Some practices are illegal but are not actually defined as corruption because they are not linked to political power. These include money laundering, fraud, drug smuggling, and black market transactions.

Another important point is the close link between politics and organized crime. Furthermore, there is even a new type of “business politician” or “entrepreneur” who “combines mediation in (licit or illicit) business transactions, first-hand participation in economic activity, and political mediation in the traditional sense” as stated by della Porta and Pizzorno (1996).

There is a specific analysis of corruption, known as the “principal-agent analysis” (Rose-Ackerman 1978), which involves considering three main agents or “actors”: the principal (the State), the private agent (citizen or company), and an agent (a public official) who in theory follows the interests of the principal. If the private party wants to obtain an advantage, he pays a bribe to the public official to help him instead of carrying out the interests of the principal. This is considered to be corruption.

Corruption can happen on two levels – bureaucratic and political. Bureaucratic or petty corruption is corruption in the public administration where bureaucrats (known as the “actors”) use their public position for financial or nonfinancial benefits. Political or grand corruption, on the other hand, is when politicians are corrupt and use their power for illegitimate financial gain and to maintain their political position. They are given the right to make decisions and to create laws, but they abuse this right in order to satisfy their own requirements.

Since political corruption has many different aspects, it is a difficult task to come up with a conclusive definition of the term. The

characteristics and objectives of political corruption depend on the polity under discussion. Nye (1967) gives this statement about political corruption as “behavior which deviates from the formal duties of a public role (elective or appointive) because of private-regarding (personal, close family, private clique) wealth or status gains: or violates rules against the exercise of certain types of private-regarding influence.” The various forms of political corruption can be recognized and analyzed by using an overall definition as a starting point.

It is worth noting that political and bureaucratic corruption are in fact inextricably linked as in the two different spheres their areas of competence can become interchangeable. However, for our objectives, the two different forms of corruption should be analyzed in practical terms.

In this encyclopedic voice, the focus is on political corruption, as opposed to general corruption; therefore one can concentrate on the political actors and the public environment in which they perform. Political corruption has a complex nature with a wide range of aspects which should be outlined. Although an extensive classification of the subject could reduce the analytical study, it is necessary in order to fully understand the different forms and characteristics.

Different Types of Political Corruption

Political corruption is not only a question of breach of formal legislations, code of conducts, and court rulings, but it also has a deeper impact on the entire political system. It can have a negative influence on decision-making, leading to the mishandling of procedures and finally the breakdown of political institutions.

While political corruption involves politicians carrying out illegal practices in order to maintain their position and improve their personal situation, it does not include police misconduct or suppression of political rivals. It is also important to clarify if the political corruption is taking place in democratic nations or dictatorial countries, due to the fact that there is lack of accountability between those in power and “the people.” There

are problems with political corruption in dictatorial countries as the legal framework is already fragile, making it difficult to assess corruption and often leading to infringement by the leaders. Therefore the legal infrastructure of the State cannot be used as a point of reference to determine the extent of political corruption.

While bureaucratic corruption can often be approached by using administrative means (auditing, legislation, and institutional organization), political corruption with its detrimental consequences needs a much stronger solution. It is necessary to use legislative, moral, ethical, and political reference points first and foremost to differentiate between legality and legitimacy regarding political corruption.

Major political reforms are essential for fighting local political corruption. In the majority of dictatorial countries, political corruption is a routine event. As bureaucratic corruption is often rife in these regimes, this encourages political corruption, which obviously varies according to the different types of authoritarianism. Rulers of these countries use corrupt means in order to empower themselves and maintain their political status.

With regard to democracies, political corruption is more of a sporadic and incidental event and can therefore often be resolved by means of reforms and reinforcing the political framework and institutions of checks and balances.

Political corruption can be divided into different categories, mainly “personal” and “institutional” or “collective” corruption. The difference depends on what extent the financial (or other) rewards from the corruption are “privatized.” While some may share the extraction with his associates, others will keep most if not all of the rewards for himself. “Personal” corruption is when politicians abuse their status to illegally obtain benefits for “personal” gain. A very common example is the acceptance of bribes by politicians and giving out benefits in return. On the other hand, “collective” corruption is a form of corruption which involves extracting resources for the benefit of a bigger group or organization, not just the private individual. Public power is abused for “private” gain, which does not necessarily mean for the personal benefits of one person

but also for “collective” gain, for private groups. It is often the ruling parties and/or potential ruling parties, national governments, and administrative authorities that become involved in this form of corruption, using the resources at hand to their own advantage.

There is a significant distinction to be made between political corruption and “lobbying” when talking about “collective corruption.” According to some (Damania et al. 2004; Harstad and Svensson 2011; Campos ad Giovannoni 2007), the definition of “corruption” only refers to petty or bureaucratic corruption, whereas any form of practice done to influence policy makers should be referred to as “lobbying.” However, this definition cannot be applied to all political systems as it does not distinguish between what is legal and what is illegal when influencing policy makers and does not take into account the regulations in all countries. While in the United States, where it is completely legal to provide pecuniary payments to policy makers (lobbying) and the definitions of petty corruption and lobbying may be applied, in other nations, the same payments are regarded as illegal and therefore politically corrupt.

It is worth looking at the procedures used to obtain private gains within the political environment in order to distinguish between the different forms of political influence (including lobbying) and political corruption. Since political corruption occurs when politicians obtain private benefits by means of nontransparent, unofficial procedures, one could say that lobbying is a particular form of corruption as it is still a way of gaining benefits from public entities or legislative organizations, with favors being given in return. However, lobbying and political corruption do have their differences which need to be noted. Lobbying is not always a case of bribes and campaign contributions. According to Austen-Smith and Wright (1994), lobbyists are capable of influencing politicians as they share competences and know-how which some politicians lack. Grossman and Helpman (1999, 2001) mention how some lobbyists even threaten politicians by saying they will give voters detrimental information about their policies, while others sway politicians with endorsements.

Other two types of corruption are “transactive” and “extortive” corruption. “Transactive” corruption is an illegal exchange between a donor and a recipient, where both actors benefit. “Extortive” corruption usually involves coercion of some sort so that the donor and people he is close to are not hurt in any way. Transactive practices are in theory based on reciprocity. It is a transaction between public officials (the State) and private actors (society) where both parties benefit from the exchange. In this corrupt exchange, there are two further distinctions to be made between “redistributive corruption” and “extractive corruption.” With “redistributive corruption,” it is the State who provides the private citizen or businessman with the resources, while “extractive corruption” is from the private actor to the State. Even though in theory the relationship is a reciprocal one, in reality this is rarely the case. In some nations or States in the world, the State plays the weaker role in transactions with society. Here redistributive corruption might take place as the mafia is rife and prevalent clientelism, which means that the State loses power as these private individuals or groups form a corrupt relationship with the State but end up with more benefits than the State itself.

“Extractive corruption,” on the other hand, is when the State has the upper hand in the relationship. This is often seen in the political framework of various authoritarian States. The corrupting group or individual plays a passive role as the State (the corrupted) has the advantage in the corrupt exchange.

The Principal Causes of Political Corruption

It is a complex task to try and find the reasons behind political corruption. Rose-Ackerman (1996) states “Many officials remain honest in the face of considerable temptation, and others accept payoffs that seem small relative to the benefits under their control. Others, however, amass fortunes. The level of malfeasance depends not only on the volume of potential benefits, but also on the riskiness of corrupt deals and on the

participants’ moral scruples and bargaining power.”

Various theories explain the widespread phenomenon of political corruption through cultural and moral factors typical of a country. When considering the factors that contribute to the onset and spread of corruption, an important role should be assigned to the cultural, ethnic, and social framework that fix in the “moral” of a country the seriousness of an act of corruption. Cultural norms, which vary from State to State, pose a boundary between a gift and a bribe or favoritism: therefore the definition of what is corrupt or not is a cultural thing (Rose-Ackerman 1999) and what can be defined by a corrupt external observer can be considered as an acceptable gift within a country.

However, the economic analysis of the causes and the extent of political corruption cannot and must not be limited to cultural factors. In fact, in addition to these, one needs to consider structural and institutional (economic and political) aspects that may override cultural interpretations (the latter is sometimes used as a way of justifying corrupt practices in some countries).

It is worth noting that the framework or “structure” of the administration and how well the institutions of a country work can influence the spread of corruption. For example, in Britain where the administrative organization is separate from the political system and the political parties were institutionalized at an early stage, there is notably less local political corruption. If there is a clear boundary between the two different systems (social and political procedures from political and economic ones), it is more difficult for politicians to enter into the bureaucratic environment.

In some countries, the presence of so-called regional brokers or different forms of mafia has meant that the social order of these States has been weakened. Due to the particularistic and fragile financial and administrative network in these countries, the State has had to depend on these “brokers” to function locally.

It is worth mentioning that each State develops in different ways, so it is perhaps incorrect to conclude that the infiltration of these groups

between the bureaucratic authorities and political system is the main cause of political corruption. That said, widespread clientelism may indeed be largely to blame for the corruption problem. Della Porta (1997) mentions how the links between clientelism and corruption and weak administration structures and corrupt practices have become “vicious circles” from which it is incredibly difficult to break free.

Another cause of political corruption identified in literature is government intervention in the economy. This intervention creates income managed on a discretionary basis by public officials, which in turn can generate corruption. Due to the growth of the welfare state and public sector, the political elite now have the monopoly over many financial resources.

It is easier for members of State and private individuals to sidestep rules and regulations as decisions are not influenced by the workings of the market but linked to these rules.

While the focus so far has mainly been on the reasons and opportunities for one to enter into corrupt practices, it is also important to look at “institutional” and “political” factors.

One significant factor is in what political context the corruption takes place. There is a widespread belief that corruption is measured by the level of democracy in a country. The more democratic a State, the less corrupt it should be. According to Friedrich (1989) the more lawful the country, the less likely corruption will evolve.

However, in some authoritarian countries, dictators are able to control the extent of corruption. In other words he will be able to decide who benefits from the State resources. For this reason, in some countries under powerful dictatorships, corruption is actually less rife. The citizens will consider these States a legitimate entity as they have the power and ability to carry out social changes and promote economic production as well as to manage law and order.

Regarding the functioning of political parties, we must consider the different methods of financing of political parties and the funding of elections. In countries such as the United States and Japan, this is now becoming a key matter with regard to political corruption.

Due to the high costs of elections and the political process in general, parties often have to look elsewhere for financial resources. They have few funds available and therefore attempt to find other means to keep their political status and to appear the most efficient in the eyes of the public.

Another important factor which may lead to political corruption is “longevity in power.”

This term refers to how governments can stay in power without being challenged by other rivals. In authoritarian States, the absence of a formal autonomous structure means that bureaucrats or public officials can take advantage and use power in corrupt ways. On the contrary, in democratic countries public accountability is guaranteed by the institutions of the “State of law.” If governments believe that their position of power is infallible, many begin to confuse the difference between State and government and as a result begin to think they are exempt from the laws that apply to everyone else.

Among the causes of greater or lesser spread of corruption are certainly the control system and the extent of the punishment related to corrupt acts. In deciding whether to engage in a corrupt transaction, an individual (be they public officials or firms), by comparing the expected benefits with the expected cost, decides to be corrupt only if the total benefit is at least equal to the total cost. The reforms designed to increase the risk of discovery and the extent of the punishment may reduce the demand for and supply of bribes. With regard to the likelihood of being discovered, it is often endogenous compared to the level of corruption, in that “the more widespread the corruption, [...] the lower the risk of being denounced” (della Porta and Vannucci 2016).

Consequences of Political Corruption

While most analysts concur that political corruption is morally condemnable, its economic and political consequences are less discussed. This is perhaps due to the fact that political corruption – complex as a concept – is difficult to both define and measure.

Corruption, in the past, has even been considered as having a positive role in some developing

countries. This was the opinion of analysts who were working within the scheme of the “modernization theory” in the 1960s. More precisely, the debate on the economic effects of corruption started with the two pioneering works of Leff (1964) and Huntington (1968), who said that corruption would stimulate economic growth mainly through the operation of two mechanisms:

- Corruption if “speedy money” can ensure that individuals are able to circumvent red tape.
- If the bureaucrats are paid directly for their work through bribery, this should make the bureaucrats work better and faster.

Therefore corruption is seen as something constructive in promoting economic growth and investment as well as helping social development in countries with weak bureaucracy, making up for the lack of adequate formal practices. However, these statements have been widely opposed by recent literature that says that corruption can have positive effects only in limited areas: they refer to the benefits arising from the assumption that State intervention creates inefficiency and corruption, shrinking them or eliminating them for the best economic growth of the system. Therefore, only in cases where the political system is inefficient, may political corruption be an improvement (see della Porta and Vannucci 1997).

With the spread of corruption, government costs will increase, public services will no longer be guaranteed as resources will begin to dwindle, revenues may be exposed, and it will no longer be possible to make effective decisions. Corruption can also have a negative influence on the purchase or even production of goods for the public. The whole process of purchasing, tendering, giving contracts, the realization of work, and payment at the end may all be affected.

A key moment in the political process of a democracy is when one needs to respond to public demand. The administration network is faced with the demands and requirements of different social groups. The function of political mediation according to Pizzorno (1992) is “to identify and interpret the needs and desires of the population; select and generalize those which can be

expressed in political terms; propose, justify and criticize policies and measures to achieve these ends or, when necessary, to explain why they cannot be satisfied.” It is the means through which interests are collected and expressed.

The efficiency of this service is then jeopardized by corruption as the demand becomes “internal” not “public.” Public demand is no longer protected as the formal restrictions of the institutions are weakened by corrupters, who are able to make decisions and take the profits from corrupt practices creating the disintegration of public demand to satisfy specific needs.

Public spending is often inextricably linked with corruption and clientelism. Public officials aim to draw as many resources as possible into their domains of power so they can receive payment for mediation as a bribe. In this way, these administrators also try to win public support as a consequence of the influence of public investment on employment. For this reason, public spending is moved into the areas where there are the most benefits from corruption and where there are fewer risks due to the discretionary characteristics of the practices. Citizen needs are not taken into account when these operations and services are carried out and many works remain incomplete or discarded altogether. In addition, in the case where politicians are not content with the sum given through bribes, public demand often remains unfulfilled. It is worth noting, however, that during purchasing transactions, there are competitive rules which mean that those participating have equal treatment once the cost of public spending has been decided.

In fact, in a widespread corrupt society, it can therefore be expected that those who formulate public demand will award the provision of public goods or a “carte” of all the companies participating in tendering. The bids are then able to be correlated and the income obtained then redistributed. Politicians or bureaucrats who have been involved in corruption in the past will then make sure that these individual companies or group of companies will definitely (or most likely) win a tender.

As a consequence, public demand will then be administered in such a way that these “protected”

companies will have an advantage in promoting their own products and will be able to benefit in the future from their “special” connections with politicians. Costs become inflated as public tenders are allocated to companies who lack the required competences, equipment, and qualifications.

Another element which politicians use to manipulate public demand is when they have real (or false) “urgent” interests. Usually the amount of public spending and its administration will be relatively high so corrupt politicians need to create a contrived emergency.

Lack of planning expertise of public administration and convoluted bureaucracy slows down the time taken to complete public operations, which in turn paves the way for corruption as discretionary proceedings in the contracting process become legitimate.

Corruption therefore creates a redistributive process from which politicians benefit: “A corrupt system of government services has the distributional disadvantage of benefiting unscrupulous people at the expense of law-abiding citizens who would be willing to purchase the services legally” (Rose-Ackerman 1978). Corruption attributes property rights to agents who then breach the rights of public interest and consequently further the tax burden which has a detrimental impact on the life of citizens.

University of Münster, Münster, Germany

Definition

The term “political economy” (PE) is mainly used in two related contexts. First, it is used to denote a multidisciplinary research field in which political

scientists, economists, legal scholars, and other social scientists investigate the relationship between the political sphere (most notably “the state”) and the economic system of different societies on Earth at different points in time. Second, social scientists, journalists, and other observers sometimes use the term PE to refer to the observable interaction of politics and business in real-world societies. Focusing on the first context, this entry gives an overview of the research field of political economy (PE) and discusses its relationship to law and economics as a research program.

Positive Political Economy: Analyzing What Is

Within the toolkit of PE, there are basically two different approaches which are currently used to analyze the relationship between politics and the economy: positive PE (explained in this section) and normative PE (see next section). Using a positive approach, researchers conduct empirical analyses in the form that they describe and explain the relationship between the political and economic sphere (i.e., what is) – but they usually do not make value judgments in the form of normative statements as to what public and private sector actors *should* do or not do: for instance, positive politico-economic analyses usually do not contain policy recommendations regarding the “right” way for the government to intervene in certain sectors or markets in the economy (i.e., what ought to be). In other words, scholars doing positive PE research first of all *describe* as precisely as possible the extent to which the state or other political actors intervene in the economic system of a society (or different societies, if a comparative perspective is taken) in a certain investigation period.

Political interventions in different sectors of the economy or particular markets may take various forms, such as government subsidies, taxation, state-owned enterprises, or regulations (Den Hertog 2000; Boettke and Leeson 2015), and may be done for various reasons, such as eliminating market failures/allocative inefficiencies, redistributing resources from the rich to the

poor, or stimulating economic growth and employment (see below). As it is often the case that firms, business associations, trade unions, and other actors within the economic system try to influence the process of economic policymaking via lobbying and other forms of leverage, in many contexts we can observe a mutual interference of the political and the economic sphere. This may also include a possible correlation between (a) the economic situation in a society and (b) the popularity and election results of government, opposition parties, or individual politicians (Lewis-Beck and Stegmaier 2013).

Moreover, it has to be taken into account that external factors such as global issues (poverty, climate change, war refugees, etc.), international organizations (e.g., World Trade Organization, European Union, International Monetary Fund, World Bank), developments in international markets, or the activities of foreign governments (e.g., tariff policy, international tax competition, sovereign debt, sovereign defaults) may influence a (sub)national PE understood as the interaction of the political and economic system in a real-world society. The fact that nation states are these days embedded, in various respects, in an international system is analyzed in the literature on “international PE” and “global PE” (see, e.g., Ravenhill 2016). In this context it should also be mentioned that there is a strand of PE research which focuses explicitly on the differences between the national economic systems of the countries in the world including different “Varieties of Capitalism” (Hall and Soskice 2001) as well as the remaining more or less socialist “command economies” or “centrally planned economies” such as Cuba and North Korea (Fine and Saad-Filho 2012, chap. 7).

However, many politico-economic analyses within positive PE do not content themselves with describing the relationship between politics and the economy but, moreover, try to *explain* the observations made in the descriptive phase of research. Which factors can explain why the state intervenes in a particular way in a society’s economy? Which explanatory factors may have driven the transformation of the “interventionist state” over time? Why do some countries show a better macroeconomic performance (economic growth,

employment, price stability, etc.) than other countries? In this spirit, for example, numerous politico-economic studies have empirically analyzed whether factors such as government ideology, powerful interest groups, fiscal pressure, socioeconomic problems (e.g., de-industrialization, unemployment, economic slump), path dependence, or globalization help explain the observable differences across the member states of the European Union (EU) or the Organization for Economic Co-operation and Development (OECD) with respect to the use of policy instruments such as public entrepreneurship, regulation, taxation, or subsidization in the decades after World War II (e.g., Leibfried et al. 2015; Obinger et al. 2016).

Similar studies exist for the less-developed world and/or for country groups including countries with “not-so-democratic” political systems. There is, for example, a politico-economic literature that describes and explains different aspects within the relationship between politics and the economy in autocratic regimes (e.g., Acemoglu and Robinson 2012; Leibfried et al. 2015, parts IV/V). Moreover, there are many studies entitled “The Political Economy of XY” which means that the particular study analyzes the interplay between political and economic factors in the specific context under investigation, for example, the political economy of migration, foreign aid, higher education, terrorism, and so on.

Normative Political Economy: Recommending What Ought to Be

PE research may be done not only in the form of empirical or “positive” analyses (as defined above) but also in the form of a *normative* analysis. This means that a specific area in the economic system is analyzed in order to come to conclusions as to what “the state” should (not) do in the area under investigation. Should the government intervene in a particular sector of the economy or a particular market by means of regulations or other policy tools? Should public bureaucrats be allowed to control certain activities of private sector firms and households? Should

regulatory agencies be mandated to supervise competition in particular sectors and markets? Such questions are addressed in the fundamental and ongoing PE debate over the proper role of the state in the economy (see Boettke and Leeson 2015, for a survey). Contributions to this debate are based, more or less explicitly, on the following major schools of thought.

Varieties of Economic Liberalism

Political economists in the tradition of Adam Smith (1723–1790), whose seminal book on “the Wealth of Nations” (Smith 1776/1981) is the “bible” for those advocating “economic liberalism” and “market liberalism,” basically argue that the state should leave the economy alone. It is assumed that there is some kind of natural tendency to equilibria in markets. That is, if there is an excess demand or excess supply, then such disequilibrium will only persist for a short period of time. According to the economic laws of demand and supply, markets will find a “market-clearing price” at which demand equals supply. In other words, direct governmental interventions into markets are perceived to be unnecessary (or even harmful) as specific markets and the economy as a whole possess “self-healing powers” in the form of the “market forces”: that is, the interplay of demand and supply coordinated via the price mechanism.

However, it should be mentioned that Smith (1776/1981) and other advocates of economic/market liberalism such as Friedrich August von Hayek (1899–1992) and Milton Friedman (1912–2006) acknowledge that society may not be left to markets alone – but that the state has to perform at least some tasks to make markets and society work. For example, political economists in the tradition of Smith (1776/1981), Hayek (1960), and Friedman (1962) consider it to be a government task to ensure that there is a functioning legal system (rule of law, laws, courts, judges, etc.) that can be used, among other things, for enforcing (i) property rights and (ii) the contracts signed by market participants. By contrast, *libertarian* political economists, who consider the possibility of a stateless society, go a step further: they argue that private governance mechanisms

(reputation, nongovernmental courts, etc.) are sufficient to enforce property rights and contractual agreements (see, e.g., Friedman 2014; Leeson 2014; Stringham 2015).

Furthermore, there are two specific variants of economic liberalism which were developed some decades ago but are still influential in the current politico-economic discourse: ordoliberalism and constitutional political economy. Ordoliberals in the tradition of the German economist Walter Eucken (1891–1950) criticize that Smith (1776/1981) and other advocates of classical economic liberalism and its *laissez-faire* approach have neglected that a market economy does not automatically increase the wealth of a nation. For example, individual markets or whole sectors of the economy may suffer from anticompetitive practices by private and/or public companies (market-entry barriers, cartelization, price collusion, competition-distorting state aid, government monopoly, and so on). Consequently, for ordoliberals it is essential that the state creates and enforces a legal order and institutions (e.g., a politically independent competition authority) that try to prevent private and governmental restraints of competition and market forces as far as possible (Eucken 1952/2004; Vanberg 2015).

In a similar vein, constitutional political economists in the tradition of James M. Buchanan (1919–2013) emphasize that markets, competition, and the economy as a whole need “rules of the game” – a “constitution” – which channel the individual self-interests of consumers, firms, and other actors (for more details, see Buchanan 1987; Vanberg 2005). Moreover, constitutional PE points out that creating and enforcing such “rules of the game” is far from trivial. Reading Eucken (1952/2004) one gets the impression that he takes it for granted that there is a benevolent government which realizes that the rules recommended by ordoliberals are beneficial for society and implements these rules. In contrast, constitutional PE assumes that not only firms and consumers but also politicians and public bureaucrats are self-interested actors. Under these conditions, not only powerful firms and interest groups but also politicians and public bureaucrats may impede the implementation of rules which could be beneficial

for citizen-consumers and society as a whole (e.g., the abolition of government monopolies, the abolition of special privileges for state-owned enterprises, better regulations for public utilities, and so on). However, what ordoliberalism and constitutional PE have in common is that both prefer a rule-based economic policy over discretionary government interventions in the economy and market processes.

For the sake of completeness, it should be mentioned that constitutional PE is part of the broader research program entitled “economic theories of politics” or “public choice theory” established by Downs (1957) and others (see Mueller 2003, for a survey). Public choice theory breaks with the welfare-economic assumption of benevolent governments working in the public interest. Instead, it is assumed that politicians and public bureaucrats (i) are primarily interested in maximizing their individual utility and (ii) “act solely in order to attain the income, prestige, and power which come from being in office” (Downs 1957, p. 28). In other words, it is theoretically assumed that political decision-makers are self-interested not only when they make private choices (as consumers, investors, landlords, and so on) but also when they make public choices in government, parliamentary committees, and other political contexts. As “older” schools of PE (e.g., classical economic liberalism in the tradition of Smith) did not pay much attention to the motivations of public sector actors and implicitly assumed that the government is primarily interested in maximizing the wealth of a nation, in the politico-economic literature, public choice theory is often denoted as the “New Political Economy” (Frey 1999).

The next step in this area has been taken by scholars working in the field of “behavioral political economy.” Therein, it is taken into account that real-world actors often do not behave as rationally and with the self-interest that economists’ traditional *homo-economicus* model predicts; this may lead to other policy implications regarding the “optimal” design of the incentive structures under which certain types of consumers, investors, policymakers, and other individuals make their more or less informed and more or less

selfish decisions (see Schnellenbach and Schubert 2015, for a survey).

Keynesianism and Other State-Interventionist Approaches

If the economy slips into recession, then hard-core economic liberals may argue that such an economic crisis may have painful consequences for firms and individuals (a drop in orders, bankruptcy, unemployment, poverty, and so on) but does not require government intervention – because thanks to its “self-healing powers” the economy will recover on its own after some time. By contrast, political economists in the tradition of John Maynard Keynes (1883–1946), whose seminal book “The General Theory of Employment, Interest and Money” (Keynes 1936) belongs to the most influential critiques of the laissez-faire approach of economic liberalism, consider it to be a government responsibility to stimulate the economy in times of economic slump (i.e., increasing government spending, reducing taxes, and so on). If the government lacks the necessary financial resources to implement an economic stimulus package, then Keynesians recommend (a) government borrowing (so-called deficit spending) and (b) repaying the debts after the crisis when government tax revenues increase due to economic growth and rising employment.

Critics of deficit-spending object that step (b) is often not conducted by government, which is one reason for the high levels of public debt observable in many countries these days. Keynesians usually respond to such criticism by arguing that costly state interventions to “stimulate,” “stabilize,” and “steer” the economy are necessary and legitimate as long as there is unemployment in a society (Krugman 2013). Complementary to fiscal stimulus packages, Keynesians propose measures of monetary policy to stimulate the economy (e.g., lower interest rates). If there is a politically independent central bank, then monetary policy is not a tool of government (i.e., politicians have no access to the tools of monetary policy).

While Keynesianism offers a macroeconomic justification for state intervention in the economy, the so-called market failure theory (for a survey,

see Stiglitz and Rosengard 2015) has demonstrated that the laissez-faire approach of economic liberalism ignores the fact that different types of market failures offer a potential justification for government action. For example, the behavior of certain firms and consumers (e.g., environmental pollution by coal-fired power plants) may create *negative externalities* for other society members. The government may implement measures (law, regulations, etc.) that force polluters to reduce or even stop producing negative externalities. Moreover, it can be expected that many society members will not pay for certain goods and services if they can consume these goods and services free of charge. However, if free riding is possible, then private actors have a low or no incentive to supply such goods and services. To secure the provision of *public goods* in the sense that no one in society can be excluded from consuming such goods, the government may step in: for example, the public good argument offers an economic argument to justify the national defense being provided by the government and financed by taxes (i.e., society members, as potential free riders, are forced to pay for national defense).

Informational asymmetries constitute another type of potential market failure. If suppliers are better informed about certain characteristics of products and services (e.g., the quality of used cars) than potential buyers, then the markets for these products and services may not function well: because it can be expected that many consumers under these circumstances would hesitate to enter a market transaction as they would fear being exploited by the better-informed sellers (e.g., low-quality, high-price products). It is also possible that buyers are the better-informed market party. Imagine, for example, insurance companies that do not know the true health status of people seeking to buy a health insurance. In situations with informational asymmetries, the government may implement measures (governmental provision of quality information, disclosure laws, governmental regulation of product quality, etc.) to mitigate these informational problems and facilitate market transactions. Moreover, the market-failure framework considers *natural monopolies* to be a potential justification for government

action. Such monopolies occur if for efficiency reasons in certain sectors or markets of the economy only one firm is doing business (e.g., the provider of a rail network, a power supply line or a water line). To avoid allowing this provider to exploit its *monopoly power* (high prices, bad quality, and so on), the government may regulate this natural monopoly (price regulation, quality regulation, etc.). And, as mentioned above in the context of ordoliberalism, the government may also intervene in some way to tackle the problem that markets and competition do not work properly due to “ordinary” monopolies and other anticompetitive practices.

It should be emphasized that the existence of a market failure does not automatically imply that the government has to solve the problem. For instance, there may be private third parties (e.g., private certification agencies) and market-based mechanisms (e.g., reputation, brand-name capital) that help market participants to overcome their informational problems, so that buyers and sellers are able to enter into mutually beneficial market transactions. In other words, in the politico-economic literature, it is not only discussed (a) whether a certain market or sector of the economy really suffers from “market failures” and “allocative inefficiencies” but also (b) which governmental or private governance mechanisms (or a mixture of both) seem to be the most suitable to solve the problem at hand (Ostrom 2010). Moreover, political economists stress that all of these mechanisms are imperfect solutions that work more or less well depending on the specific real-world context in which they are used (Wolf 1993). And it may be the case that government action to solve a market-failure problem may create new problems (for an overview of the politico-economic debate on “government failure,” see Keech and Munger 2015).

A normative yardstick that is often used by economic liberals to assess whether state activity is necessary to mitigate a certain type of market failure is the so-called subsidiarity principle. According to this principle, government action is only necessary if private market solutions and private governance mechanisms fail. A brief and oft-cited summary of this principle can be found

in the book “Principles of Economic Policy” by Eucken (1952/2004, p. 348): “The structure of society should follow a bottom-up approach. What the individuals or the groups can autonomously accomplish should be done on their own initiative and to the best of their abilities. And the state should only intervene in those cases in which its assistance is indispensable” (own translation, K.M.). By contrast, political economists that have a less individualistic and more state-centered view of economy and society may start from the paternalistic, state-interventionist assumption that the state is automatically responsible for solving market-failure problems (for a survey of the politico-economic literature on paternalistic government, see Le Grand and New 2015). In democratic societies, the ultimate decision-maker in this context is the government in power – and this decision-maker is certainly free to ignore the normative (and often conflicting) policy recommendations made by political economists and other experts.

Marxism and the Social Question

Economic liberalism and its belief in markets and competition have always been the target of criticism. Karl Marx (1818–1883) and Friedrich Engels (1820–1895) have argued that it is a basic feature of capitalist market economies that the “working class” (the so-called proletariat) is exploited by business firms and their owners (the “capitalists”; see, e.g., Marx and Engels 1848/2002). The state is seen as an agent of the so-called bourgeoisie (including the capitalists) which constitutes the ruling class in society. Marx and Engels predicted that capitalism will be overthrown through a “proletarian revolution” that leads to socialism and, eventually, to communism (including a classless society). It is beyond the scope of this paper to critically review everything that has been written by Marx, Engels, and their followers under the label “Marxian Political Economy” about imagined and real existing types of capitalism, socialism, and communism (for a survey, see Fine and Saad-Filho 2012). Nor do we discuss the many problems of “command economies” or “centrally planned economies.” However, Marx and his followers have repeatedly

pointed out a serious problem which many capitalist market economies still have to cope with: it may be the case that an economy consists of a system of well-functioning, efficient markets, but this system produces social problems.

For example, in many countries we observe income and wealth inequality among society members. While hard-core economic liberals may argue that such inequalities have to be accepted and simply reflect individual differences in performance and success on markets, other political economists argue that the state in the name of “social justice” has to tackle distributional problems via redistribution (see Piketty 2014, for an overview of this debate). And even economic liberals that are skeptical of state interventions, such as Hayek (1960) and Friedman (1962), take it for granted that those society members who, for whatever reason (e.g., disease, disability), are not able to earn money in the labor market should receive publicly financed welfare benefit payments ensuring a minimum income needed to exist. Whatever political economists from different schools may think about social problems and their solution – in the end, however, in democratic societies the scope and structure of the welfare state are determined in the political process.

Political Economy Meets Law and Economics

Last but not the least, we have to address the question of what law and economics (LE) as a research program has to do with PE as a multidisciplinary endeavor. First of all, we can observe that terms, concepts, and tools from the toolkit of PE (market failure, externalities, public goods, efficiency, utility, welfare, constitutional PE, behavioral PE, and so on) are used by LE scholars and in LE textbooks as well (see, e.g., Towfigh and Petersen 2015). In this context, it should also be mentioned that economists belonging to the LE movement have made important contributions to the research field of PE as sketched above. See, for example, the studies on externalities and public goods by Ronald H. Coase or the contributions by George J. Stigler, Richard A. Posner, and Samuel

Peltzman to the economic theory of regulation (see the bibliographies in Den Hertog 2000; Boettke and Leeson 2015). In other words, many of the concepts presented above under the label PE, which is mainly used by political scientists, economists, and “political economists,” are presented in LE publications under the label LE, which is mainly used by legal scholars, economists, and supporters of the LE movement. And while some may classify Coase, Stigler, Posner, and Peltzman as economists or LE scholars, others may classify them as political economists.

Likewise, Persson and Tabellini (2003), La Porta et al. (2008), and similar studies investigating the interplay of legal institutions and the economy are oft-cited in the PE as well as in the LE literature. In any case, it should be clear now that political economists and LE scholars who are interested in analyzing different aspects of the interplay between the political and economic sphere of society share a common terminology. This offers opportunities for research cooperation and interdisciplinary research – but does not mean that the disciplines participating in the “joint ventures” labeled PE and LE would have lost their idiosyncrasies and specific strengths. For example, as noted above, in the politico-economic works of Hayek, Friedman, Eucken, and Buchanan it is argued that “the state” should provide a legal framework which ensures that markets and competition work well; however, these thinkers do not say much about the fundamental issue of how exactly the specific legal framework for a specific market or economic sector in a particular real-world society should be designed and enforced (contract law, competition law, capital market law, energy law, environmental law, and so on). That is, legal experts are necessary to bridge the gap between normative politico-economic theories of the proper role of the state and practical public policy.

Moreover, it can be observed that in the positive, empirical branch of PE and LE, there seems to be a methodological convergence in the sense that scholars doing empirical research in this area basically use the same toolkit, consisting of various quantitative and qualitative methods (statistical techniques, document analysis, field

research, etc.; Towfigh and Petersen 2015). As we have seen above, however, such consensus cannot be observed in the normative branch of PE. Looking through the theoretical – some would say “ideological” – lenses of different schools of PE in many cases brings us to different conclusions regarding the question of what the state should do (or not do) in the particular area of the economy under investigation.

Politicians

Benny Geys^{1,2} and Karsten Mause³

¹Department of Economics, Norwegian Business School BI, Oslo, Norway

²Vrije Universiteit Brussel, Ixelles, Belgium

³Department of Political Science (IfPol), University of Münster, Münster, Germany

Definition

Politicians are persons involved in the process of public policymaking in their role as members of governments, parliaments, political parties, and other political bodies at the (sub)national level (e.g., local government, state legislature, national parliament, etc.) as well as within the supranational political arena (e.g., United Nations Security Council, European Union institutions, and so on). Many politicians get into office through a democratic election, while others are selected or appointed to a public office. For many politicians, politics is a full-time job, while for others, it remains an activity in addition to a main job as a lawyer, teacher, or entrepreneur. This entry takes stock of what law and economics (LE) scholars have contributed to the large social science literature on politicians.

The Law and Economics of Politicians

Analyzing what politicians do belongs to the “core business” of political scientists. However, the law and economics discipline has extensively contributed to this multidisciplinary research field as well. Given the large number of articles and books, it is beyond the scope of this entry to review everything that LE scholars have written about “politicians.” Rather, we focus on the

following aspects: (1) the motivations of politicians, (2) politicians as lawmakers, (3) politicians and interest groups, and (4) the design and effects of the (legal) rules under which politicians act.

What Do Politicians Maximize?

LE scholars including, for instance, George J. Stigler and Richard A. Posner are also active contributors to the field of “public choice.” Public choice theory in the tradition of Downs (1957) breaks with the welfare-economic assumption of benevolent governments working in the public interest and maximizing the wealth of the nation. Instead, it assumes that politicians and public bureaucrats (i) are primarily interested in maximizing their individual utility and (ii) “act solely in order to attain the income, prestige, and power which come from being in office” (Downs 1957, p. 28). In other words, it is theoretically assumed that political decision-makers are self-interested not only when they make private choices (as consumers, investors, landlords, and so on) but also when they make choices in government, parliamentary committees, and other political contexts (Mueller 2003; Posner 2014, chap. 20).

Whether real-world politicians really behave in line with predictions derived from the *homo-oeconomicus* assumption used in economic theories is, of course, an empirical question – and presumably depends on the specific context within which the individual politician acts. In democracies, an individual politician’s private utility maximization is usually constrained by a number of mechanisms that may channel his/her self-interest and act as a disciplining device, e.g., his/her political party, political competition, press freedom, an independent judiciary, nongovernmental watchdog organizations, a politically interested electorate, and so on. However, in the absence of such constraints, a public choice perspective would lead to the expectation that politicians could have a low or even no incentive to pursue the public interest (Mueller 2003; Bovens et al. 2016).

Within the vast LE literature, there are a number of empirical studies indicating that many politicians “shirk” their duties in their last period

in office, that is, once citizen-voters are no longer able to punish them at the next election (see Geys and Mause 2016, for a survey of the “shirking” literature). Moreover, there is a large literature on “political corruption” demonstrating that politicians at times illegally abuse their power for their private gain (money, privileges, jobs, and so on). LE researchers have made numerous contributions to this literature, discussing in particular the question of whether changes in the incentive structures under which politicians act (e.g., more severe punishment, transparency laws, better pay, etc.) help to reduce the probability of corruptive practices occurring (Rose-Ackerman and Palifka 2016).

Politicians as Lawmakers

Otto von Bismarck (1815–1898), the first Chancellor of the German Empire lasting from 1871 to 1918, once said: “Laws are like sausages. It is better not to see them being made.” Obviously many social scientists have ignored Bismarck’s advice since there is a large literature analyzing different aspects of the role of politicians as “makers” of public policy and “producers” of constitutions, laws, regulations, and other outputs of the political process (for surveys, see McCubbins et al. 2007; Parisi 2011; Posner 2014, chap. 20). LE scholarship has contributed to this multidisciplinary research field especially by analyzing and rethinking the system of checks and balances in which policymakers in different political systems are embedded. This literature suggests that it makes a difference whether policymakers “produce” laws and regulations in a representative democracy, a parliamentary democracy with a strong second chamber, a presidential democracy, a direct democracy with a powerful electorate, and so on (Mueller 2003; Persson and Tabellini 2004). Moreover, supranational actors – such as the European Union (EU), the North Atlantic Treaty Organization (NATO), and the United Nations (UN) – have been found to influence (sub)national policymakers’ decisions (Dreher and Lang 2016).

An interesting phenomenon in this context is that some political systems allow politicians to

make laws and regulations with direct implications for themselves. For example, politicians active as lawyers occasionally become involved in making laws that favor the legal profession (Matter and Stutzer 2015). Likewise, the desire of political parties to establish and maintain electoral thresholds may be interpreted as an anti-competitive instrument used to erect a barrier to entry for new parties (Wohlgemuth 1999). A closely related issue is whether politicians should legally be allowed to set their own salaries and other parts of their compensation package – as is currently often the case (Mause 2014). As noted above, problems might occur if politicians’ self-interest and the public interest collide. If citizens get the impression that politics is some kind of “self-service store” for the “political class,” this might have an effect on voter turnout, election results, and trust in politicians and the political system as a whole.

Politicians and Interest Groups

Within any democratic society, interest groups (such as firms, trade unions, employers’ associations, taxpayers’ associations, churches, rabbit breeders associations, rifle associations, and so on) have a strong incentive to lobby for their interests and achieve favorable regulations, government subsidies, protection of monopolies, and other things. Imagine, for example, the case of a powerful association of business enterprises that would prefer to keep its market closed to competitors. Any market entry barriers benefit the incumbent firm(s) as they reduce the level of competition in that particular sector of the economy. This is likely to result in higher prices (and lower consumer surplus) compared to a situation with more competition, but in higher profits for the firms active in this market. Clearly, this business association would have a strong incentive to ensure – via various lobbying activities – that policymakers do not open the market. In the public choice and LE literatures, the phenomenon sketched above is denoted as “rent-seeking” (see Congleton and Hillman 2015, for a survey of the voluminous theoretical and empirical rent-seeking literature).

Politicians are a natural objective for lobbying activities, which can take the form of, for example, information campaigns, dinner invitations, or political (campaign) donations. While certain lobbying activities can be beneficial by improving the information available to policymakers, they can also become a serious societal problem if they influence legislators, legislation, and/or the allocation of public funds in favor of specific groups (Hodler and Raschky 2014). Such political favoritism indeed distorts spending allocations away from the normative principles that ideally drive them, which from a theoretical perspective “lowers aggregate social welfare, [and] creates inequality across social groups” (Bramoullé and Goyal 2016, p. 23). As a result, a vast literature has investigated the link between lobbying activities and political outcomes. For example, studies linking firms’ political donations to congressional voting patterns and public procurement contracts (see, e.g., Gherghina and Volintiru 2017, including a literature review).

As noted above, it is not only business firms and other special interest groups that may try to influence policymakers to make decisions favorable to their particular firm or industry. In this context, a specific type of “rent-seeking” by politicians occurs when the latter use their influence and power to obtain and defend special privileges that “ordinary citizens” do not have (Mause 2014).

Getting Incentives Right: Regulating Politicians

Scholars working at the intersection of LE and constitutional political economy in the tradition of Buchanan (2008) and others tend to maintain a strong focus on the “rules of the game” for politicians. There is, for instance, a substantial literature analyzing how the design of the working conditions in the political system (e.g., wages, term limits, etc.) incentivize individuals to stand for election – and drive politicians to make policies in the public interest. For example, the fact that candidates for a public office have to disclose parts of their income and/or wealth to the public is argued to have an effect

on the incentive to run for office (Djankov et al. 2010; van Aaken and Voigt 2011; Braendle 2016). This also touches on the issue of accountability regarding “shirking” politicians and how to deal appropriately with such behavior (Geys and Mause 2016). Given the potential (self-) selection effects this induces, should there be compulsory attendance for politicians at parliamentary debates, roll-call votes, or committee meetings (possibly with penalties for nonattendance)?

Likewise, there remains an intense debate as to whether existing regulations with respect to donations to politicians and political parties, politicians’ sideline jobs, partisan patronage and favoritism, and political corruption are sufficient (see Rose-Ackerman and Palifka 2016, for an introduction to this research field). The rules of the political game may be respected by many politicians, but there will most likely always be at least some “black sheep” that break the rules and behave “opportunistically” in the sense of Williamson (1985, p. 47): “By opportunism I mean self-interest seeking with guile. [...] More generally, opportunism refers to the incomplete or distorted disclosure of information, especially to calculated efforts to mislead, distort, disguise, obfuscate, or otherwise confuse.”

Bradford, UK

Abstract

This entry discusses the problems of definition of pornography and the problems of defining an optimal regulatory strategy.

Synonyms

Porn

Judge Richard A. Posner has repeatedly applied orthodox free market Chicagoan law and economic thinking to porn in several of his books (*Sex and Reason*, *Frontiers of Legal Theory*, *Economic Analysis of Law*). Heterodox economist David George (2001) briefly discusses porn as an instance of what he calls “preference pollution.” In this scenario, free markets impose weakness of will upon us leading to the “wrong choice” of consumption basket. We end up less well-off than we might otherwise have been because we are weak and fall prey to market pressures to consume porn. As we are now over a decade further on in the Internet world, his point would presumably be made even more forcefully now.

Regulation of porn, by laws, requires a definition of the activity so that it can be actioned.

This is a long-running problem. Everyone thinks they know what the word “pornography” means, yet legal definitions have been difficult to agree upon. This problem increases as laws come

Samuel Cameron has retired.

into force relying on gradation into extreme or hard-core porn as illegal and lesser types as not. The original meaning was as a description of the life and activities of prostitutes. This derives from the Greek, *pornographos* (*porne* = prostitutes and *graphein* = to write). It acquired its present meaning in the nineteenth century and seems to have two key elements, one being the obscenity of depiction of sexual acts and the other, the exploitation of workers in the production of the material and/or the consumers of the material. There are thus two areas of legislation. The first is to deal with protection of consumers, in their own best interests, and the second to deal with the workers in the industry. The latter has been particularly important in the American economy and less developed in some other territories. A notable instance of this is to be found in the 1995 Child Protection and Obscenity Enforcement Act, passed in the USA following the 1986 report of the Meese Commission. This required porn filmmakers to keep detailed records proving that no underage performers were used.

Much legislation has tended to be under the rubric of "obscenity." Porn has frequently been treated in legal matters as material "with a tendency to deprave or offend" where the decision on how depraving or offensive the matter is being left to a judge and/or jury. American Supreme Court decisions have illustrated the difficulties of Justice Potter Stewart's claim that he would know pornography "when he saw it." Lurking in the Supreme Court decisions has been the notion of an "average Justice Brennan's so-called 'limp dick' test became entrenched as a dividing line in movie censorship person" standard, that is, the judges are agents representing the median preferences of the population.

In terms of welfare economics, the simplest case for control is that porn may be viewed, as mentioned earlier, as a form of "social pollution." Controls can be aimed at the supply or at the demand. As with general crime, the expectation is that punishment will be proportional to harm. The particular dividing line in this respect is with respect to child pornography. The era of more liberal attitudes toward this in some areas of Europe (particularly in Denmark) has now passed.

Most of Europe makes child porn illegal but many parts of the world do not have explicit laws against it. Part of the more liberal attitude, in the past, related to deterrence and safety valve effects. If punishment does not deter then it will occur costs which bring no benefit other than the public satisfaction with retribution and the possible enhanced safety of taking the offenders out of circulation. The latter effect will be negligible for child (or any porn) if there is no complementarity between porn consumption and other offenses. If the offenses are a substitute good for porn consumption, then society can potentially have net benefit from liberal treatment of offenders. This was the core point of the criminologist Berl Kutchinsky about the Danish experience (see Kutchinsky (1985); Kutchinsky and Snare (1999)).

Various empirical studies have been carried out on the possible relationships between availability of pornography and the frequency of sexual crimes. Ad hoc inferences have also been made about cross-country differences in such offending between repressive and more liberal regimes. Due to problems of data accuracy and consistency and difficulties in causality testing, there is no conclusive evidence from these studies that pornography does have a harmful effect. In any case, legislation and policy proceed largely parallel to evidence. The chief force for change in regulation is the continued evolution of Internet markets.

Supply-side regulation is inherently difficult in Internet markets. Thus demand-side controls in Internet markets have been growing following the style of those for circulating media. For printed magazines, we have seen requirements for shrink-wrapping in an opaque cover and/or location in a position in a shop where it is not easily seen, by accident, by children or others likely to take offense. In the case of broadcast porn, we have seen restriction to channels that are not "free to air" (FTA) and can therefore be blocked to inappropriate consumers. However there has been a proliferation, in many countries, of FTA "Babestation" channels which grew up under the rubric of being nonsexually

offensive chat/social entertainment sites. Frequent complaints against breach of this in the UK have been lodged with relatively few fines being levied by the broadcast regulators. These stations continue to broadcast on FTA television material which regular channels would not be allowed to provide. Such channels operate also on the Internet where they provide more and more graphic content. This is of course material that would be legal as porn per se. It would not be an offense to possess copies for private use.

Prevention of access to Internet porn requires that the would-be consumer is unable to access the site. This can be accomplished by specific software that refuses connection to a site. Such software has been mainly aimed at parents wishing to prevent children seeing porn. ISP (Internet service provider) can also lock certain sites as unsuitable.

A fundamental difficulty with expanded regulation is the potential loss of revenue to ISP if blocking is used especially if “opting in to porn” on user sign-up is invoked. This does not come from sales of porn as such but from the degree of Internet traffic it generates which proportionally raises the advertising-based revenue streams. ISP may not be keen on surveillance but its use to target offenders is of much less revenue threat and is very difficult to resist both technically and also politically due to the threats of terrorism.

From a legal point of view, there is a change in some recent results of police seizure of people’s computers and Internet history records. That is, intent is coming to the fore as a ground for prosecution, as opposed to mere possession. In 2014 arrests began from a global initiative involving 19 countries which explored data from around 10,000 Internet users had accessed more than 30 websites carrying pedophilia. For practical reasons, the number of suspects was narrowed down to just over 400 suspects of distributing pedophile images. The 19 countries where warrants were executed were Australia, Belgium, Canada, France, Germany, Israel, Italy, Japan, Korea, the Netherlands, New Zealand, Portugal, Russia, Spain, Sweden, Taiwan, Turkey, the UK and the USA. One of the cases in the 2014 trial of

entertainer, Rolf Harris, in the UK for sex offenses was brought on grounds of accessing child porn. His Internet searches were offered as evidence by the prosecution on the grounds that he had clearly used words intended to find sexual images of children. His defense pointed out that the models, on such sites, were simply posing as underage given that compliance with employment directives was observed by these sites. Hence, on a consumption-based charge, he was innocent. This was upheld but we see here serious grounds being given for a charge based on intent.

The above measures are intrinsically based on restricting the quantity of a good which has “bad” effects. They incur costs and thus it is possible that there could be “too much” prevention of porn in the sense that aggregate social benefit, of so doing, exceeds aggregate social cost. The costs may include wrongful arrest and prosecution.

Traditional economic models might suggest that price regulation is likely to be more efficient than quantity regulation. A porn tax might seem attractive (analogously to a Pigouvian pollution tax), but in terms of more modern welfare economics, the option of selling permits, or licenses, to porn merchants would seem a better price-based solution. While the sale value of the permits could be determined at a level that is social welfare maximizing, both approaches face the difficulty of being seen as dangerous due to making porn seem like a legitimate business activity.

Upon passing by a small village of barbarians,

Julius Caesar asserted

“[f]or my part, I had rather be the first man among these fellows than the second man in Rome”.

(Plutarch)

Abstract

People consume because others consume, maintained Veblen in 1899. More recently, theoretical, empirical, and experimental articles have argued that people constantly compare themselves to their environments and care greatly about their relative positions.

Given that competition for positions may produce social costs, we adopt a *Law and Economics* approach (i) to suggest legal remedies for positional competition and (ii) to argue that, because legal relations are characterized in turn by positional characteristics, such legal remedies do not represent “free lunches.”

The Issue

A positional good is an economic good that depends largely on comparison of one’s own consumption with that of others (Hirsch 1976; McAdams 1992; Pagano 1999; Hopkins and Kornienko 2004; Schneider 2007; Vatterio 2009; Fiorito and Vatterio 2013). Positional concerns refer to the fact that individuals consider their rank, relative standing, or position when they evaluate their situation and act upon this evaluation.

For instance, in the above quotation from Plutarch, Julius Caesar (Roman emperor) admitted his willingness to renounce the larger and better

private and public goods that he could consume in Rome (e.g., *panem et circenses*) to gain the position of sovereign (which is a positional good) in a relatively poorer community. Likewise, in John Milton’s *Paradise Lost*, Satan stated that it is “[b]etter to *reign* in Hell, than *serve* in Heaven” (emphasis added). In other words, individuals like Caesar and angels like Satan prefer to be the first or the leader in a reference group, even if it is a second-rate one (e.g., a barbarian village or hell). The recent experimental literature corroborates this “position matters” argument (e.g., Solnick and Hemenway 1998, 2005).

Similarly, Hopkins and Kornienko (2004) state, “it is not just that the car is big [enough for needs] but that it is bigger than those owned by the neighbours that also matters” (Hopkins and Kornienko 2004:1087–1088). Carlsson et al. (2007) test this size-matters hypothesis with an experiment and find that people prefer cars bigger than the average size in their society.

A further example is provided by San Gimignano, a small Italian town close to Florence and Siena. In the past, San Gimignano was characterized by about 80 towers (today there are “only” 20 of those towers remaining). The families of San Gimignano did not build towers to live in them or for military defense (because they were unfit for habitation or for fortification) but rather to display their power, affluence, wealth, and status to the rest of the community. Similarly to the “size-matters” argument in Hopkins and Kornienko, in the case of San Gimignano’s towers, tallness matters.

Positional concerns are pervasive in numerous socioeconomic domains (see Solnick and Hemenway 2005) and play a pivotal role in people’s happiness (e.g., Frey and Stutzer 2002; Clark et al. 2008). This entry wants to deal with negative effects of positional competition and institutional remedies.

Some consequences of competition for positions are illustrated by the following example concerning a labor relationship (see Frank 2012). Consider two types of employment contract, distinguished between wage and safety at work. The former type of contract is characterized by a wage relatively higher *but* a level of workplace safety

relatively lower than those of the latter type. Denoting with w_L , w^H , and R , respectively, the low(er) wage, the high(er) wage, and disutility for unsafe work (e.g., risks of injuries) assume that

$$w_L > w^H - R \tag{1}$$

That is, the disutility due to an unsafe workplace is relatively higher than the increase in wage. In other words, the choice of the contract with unsafe work may produce social costs (i.e., higher health expenditures).

In this game, the Nash equilibrium (*safe work and low wage* for both parties) is efficient (see Fig. 1).

Now assume that positions matter. For instance, a worker with a higher wage can acquire a relatively larg(er) car: that is, there is a positive utility POS deriving from position (e.g., being the worker with the highest wage in the reference group) as well as a corresponding negative utility – POS (for being the worker with the lowest wage in the reference group). The choice of the worker changes as in Fig. 2.

In particular, if $w_L - \text{POS} < w^H - R < w_L < w^H - R + \text{POS}$, then the game becomes a prisoner’s dilemma: the Nash equilibrium (both

parties choose *unsafe work and high wage*) is Pareto inefficient.

Indeed, even if the second type of contract (lower wage *but* a higher level of workplace safety) is efficient in terms of social welfare (because health expenditures with lower workplace safety are relatively higher than the increase in wage, cf. Eq. 1), each worker prefers the first type of contract because positional competition (on the wage) is important. This means that agents may substitute a non-positional good (i.e., safety at work) with a positional good (wealth), thus causing social costs (i.e., health expenditures). Moreover, if every employee chooses the employment contract with a high wage, then no agent will enjoy a positional advantage in wealth. In equilibrium, no one will consume a positional good (i.e., the biggest car), but all workers will “consume” a lower level of safety at work.

Hence, the consumption of positional goods may produce the following social costs:

1. Agents could substitute a non-positional good (e.g., a private and/or public good) with a positional good, leading to suboptimal equilibria (see also Frank 1985a, b, 2008).

Positional Goods and Legal Orderings, Fig. 1 The trade-off between safety (or health) and wage

		Friday	
		Safe work and low wage	Unsafe work and high wage
Robinson	Safe work and low wage	$w_L; w_L$	$w_L; w^H - R$
	Unsafe work and high wage	$w^H - R; w_L$	$w^H - R; w^H - R$

		Friday	
		Safe work and low wage	Unsafe work and high wage
Robinson	Safe work and low wage	$w_L; w_L$	$w_L - \text{POS}; w^H - R + \text{POS}$
	Unsafe work and high wage	$w^H - R + \text{POS}; w_L - \text{POS}$	$w^H - R; w^H - R$

Positional Goods and Legal Orderings, Fig. 2 The choice when positions do matter

2. Because the “parallel investments” in obtaining positional goods may lead to the situation in which no one consumes positional goods, positional competition may waste the economic resources of agents (see Pagano 1999).

How should institutions regulate the competition for positions? What are institutional remedies? A first group, say of *Public Economics*, involves Pigouvian remedies, i.e., a progressive consumption tax on luxury/positional goods (see Frank 1985a, b, 2008). A second group, say of *Law and Economics* (see definition of Marciano 2016, ► “[Economic Analysis of Law](#)”), may consider rules as means to reduce social costs due to positional competition. This second group is the focus of the next two sections.

Institutional Remedies

How could norms reduce social costs due to positional competition? We investigate three types of *Law and Economics* remedies: norms which (i) restrain/punish the consumption of positional goods, (ii) make the consumption of non-positional goods compulsory, and (iii) encourage cooperation by agents competing in positions.

(i) *Restraining the consumption of positional goods*

Because of the social costs deriving from the consumption of positional goods, the lawmaker may penalize or prohibit the consumption of positional goods. An example is the so-called sumptuary law – Black’s Law Dictionary defines such a law as made for the purpose of restraining luxury or extravagance, particularly against inordinate expenditures in the matter of apparel, food, furniture, etc. Sumptuary laws were enacted in Ancient Greece and Rome, from the Middle Ages onward in France and England, and again, in the seventeenth century, in the American Colonies and in feudal Japan (cf. Dari-Mattiacci and Plisecka 2012).

For instance, in ancient Rome, a series of laws governed the materials of which garments could be made and the number of guests at entertainments. In France, Philip IV issued regulations governing the dress and the entertainments of the various social orders. Under later French kings, the use of gold and silver embroidery, silk fabrics, and fine linen was restricted. In 1433, an act of the Scottish Parliament prescribed the lifestyle in Scotland, even going so far as to limit the consumption of pies and baked meats. In feudal Japan, an imperial edict regulated the size of houses and imposed restrictions on the materials that could be used in their construction. Rules in the Tokugawa period in Japan specified the sorts of toys that parents could give their children. For the Aztecs, *macehualtin* – members of the laboring class who displayed finery and precious objects – could be put to death. An interesting and “romantic” view on sumptuary law is in *Dei Sepolcri* by Ugo Foscolo, where the author condemned the Napoleon edict of Saint-Cloud on *positional* expenditures for funerals.

However, attitudes on sumptuary law changed with the Enlightenment, industrial mass production, and consumer-oriented societies. For this reason, there are today limited examples in which legal norms discourage or punish the consumption of a positional good – an exception could be represented by the case of the case of “power”: Power is a positional good (Pagano 1999; Vatiéro 2009) whose consumption in liberal countries is legally and formally limited, e.g., by antitrust law, labor law, and public law (see Vatiéro 2009), which may represent modern forms of sumptuary norms.

Although in liberal society there are not clear examples of legal norms which punish the consumption of positional competition, social norms may do so. This is the case of the tenth commandment “You shall not covet your neighbor’s house; you shall not covet your neighbor’s wife or his servant or his ox or his donkey or anything that belongs to your neighbor.” Because the commandment implies punishment in the case of *envious* choices and conducts, it should affect the behaviors of agents, at least for Christians and Hebrews, and may mitigate positional competition.

(ii) *Making the consumption of non-positional goods compulsory*

Because of the social costs due to the consumption of positional goods, the lawmaker may render (a minimum level of) the consumption of non-positional goods compulsory. That is, the legal system may provide norms which reduce the substitution between positional goods and non-positional goods by defining a non-renegotiable minimum consumption of non-positional goods.

Indeed, labor law establishes non-renegotiable minimum conditions on safety at work. For instance, the employer must provide and maintain a working environment that is safe and without risk to the health of the workers; and workers must use safety equipment with care and act according to prescribed instructions to safeguard their health and protect themselves against injury.

Accordingly, most labor law in the Western countries forbids the renegotiation of these conditions on safety, even against the worker's will. Indeed, the worker may prefer a higher wage at the expense of safety at work. From the perspective of positional competition, this prohibition on renegotiating minimum safety conditions at work is efficient because it reduces the emergence of social costs related to positional competition.

(iii) *Encouraging cooperation among positional competitors*

Because of the social costs due to the consumption of positional goods, the policy maker may encourage cooperation and collaboration among agents (i.e., positional competitors). That is, the wasteful competition for positional goods represents a problem of coordination among agents. For instance, in the case of employment contracts, workers' choices lead to a Pareto-inefficient equilibrium with a lower level of safety at work and nobody consuming a positive level of positional goods. Workers may coordinate to move to a Pareto-superior equilibrium (where nobody still consumes a positive level of positional goods, but all parties have higher levels of safety at work). This implies that cooperation among agents (e.g., workers) may improve the efficiency

of individuals' choices (e.g., in terms of labor safety).

In other words, the labor laws which sustain worker unions and collective bargaining could encourage coordination/cooperation among workers and, because unions take the negative effects of positional competition into account, reduce the substitution of non-positional goods for positional goods.

Legal Positions as Positional Goods

While in the preceding section we argued that legal norms may diminish inefficiencies due to positional competition, in this section we illustrate how legal norms in turn create positional concerns.

According to legal theorists such as Wesley N. Hohfeld and old institutionalists like John Commons, each jural relation is linked to a jural correlative (Pagano 2000; Vatiéro 2010; Fiorito and Vatiéro 2011). The above figure displays the eight fundamental conceptions with which all legal problems may be stated: claim, duty, liberty, no right, power, liability, immunity, and disability (Fig. 3).

Claim/duty relation. In a simplified situation with two agents, say a Dominus and a Servus, a *claim* means that the Dominus has a state-sanctioned assurance that the Servus will behave in a certain way toward Dominus. However, this occurs if and only if the Servus has the *duty* to engage in such behavior with respect to Dominus. That is, a duty is the legal position of the Servus, who is commanded by society to act for the benefit of Dominus, and who will be penalized by society for disobedience. Hence, the correlative of a claim is a duty.

Liberty/no-right relation. *Liberty* stands for one's freedom from the claim of someone else.

	Jural correlatives			
<i>Dominus</i>	Claim	Liberty	Power	Immunity
<i>Servus</i>	Duty	No-right	Liability	Disability

Positional Goods and Legal Orderings,
Fig. 3 Fundamental legal conceptions

Similar to the claim-duty relationship, the Dominus has a liberty to behave in a certain way toward Servus if and only if the Servus has *no-right* toward the Dominus to prevent the Dominus from behaving in a certain way. No-right is therefore the legal correlative of a liberty of another party.

Power/liability relation. *Power* is the legal ability to do certain acts that alter legal relations. The Dominus’s power is when the Dominus’s own voluntary act will cause new legal relations between the Dominus and the Servus, against the Servus’s will. This implies that, whenever a power exists, there is at least one other human being whose legal relation will be altered when the power is exercised. The person whose legal relation will be altered is under a *liability*.

Immunity/disability relation. Finally, *immunity* is any legal situation in which a given relation vested in one person cannot be changed by acts of another person. Correlatively, the one who lacks the legal ability to alter the other individual’s legal relations is said to be under a *disability*.

The correlative nature of legal positions means that each legal position is available to an individual if and only if a corresponding legal position is occupied by some other individual. In particular, legal positions are adversarial in nature (see also Vatiéro 2013a). For instance, claims of one individual imply, at the same time, duties for some another individual and vice versa. That is, the set of actions that defines the claims of the Dominus imposes duties on some individual(s), e.g., the Servus. This brings about the consumption of legal positions with opposite signs: claim by the Dominus, as his/her desired output, and duty by the Servus, as his/her costly input. In a similar manner, the power-liability relationship consists of Dominus’s benefit (i.e., the power) as well as Servus’s cost (i.e., liability). Hence, any utility deriving from rights and powers must jointly relate with disutility deriving from duties and liabilities (see Fig. 4).

Unlike traditional economic goods, jural positions inevitably involve consumptions and utilities with opposite signs. *Everyone* cannot

Claim/Power	Duty/Disability
<i>Benefits</i>	<i>Costs</i>
<i>Desired output</i>	<i>Costly input</i>
<i>Utility</i>	<i>Disutility</i>

Positional Goods and Legal Orderings, Fig. 4 The adversarial nature of legal relations

consume claims, liberties, powers, and immunities; for some individuals, the exercise of these jural positions must imply the exercise of “unfavorable” correlative jural relations (i.e., duties, no rights, liabilities, and disabilities). Because of their adversarial nature, we can represent jural positions as positional goods (see also Pagano 2000; Vatiéro 2013a).

This means, moreover, that the definition of rights, duties, powers, etc. with the purpose of mitigating positional concerns, as illustrated in the previous section, can in turn create positional concerns because judicial positions are positional goods. Following Coasean main contribution, no institution is a “free lunch” (Grillo 1995; Pagano 2012; Vatiéro 2013b; Pagano and Vatiéro 2015). Thus, in the case of positional goods one should take into account benefits deriving from an institutional arrangement able to mitigate positional competition and reduce related social costs but also the costs involved in that institutional arrangement which is in turn characterized, owing to the adversarial nature of legal relations, by positional concerns.

Conclusions

Positions matter in the choices and happiness of agents. People constantly compare themselves to their environments and care greatly about their relative positions, which impact on their choices.

The consumption of positional goods may produce social costs. On the one hand, agents may substitute a non-positional good with a positional good; on the other hand, as an arms race, positional competition may waste the economic resources of positional competitors. Both consequences lead to suboptimal equilibria.

Law and Economics scholars should investigate legal remedies for social costs due to competition for positions. They should take serious account of the fact that legal remedies are not free lunches. In this regard, future research could investigate the costs and benefits that would derive from the definition of a Coasean market (Cf. Medema 2014, ► [“Coase Theorem”](#); Bertrand 2015, ► [“Coase and Property Rights”](#) in this encyclopedia) for positional goods.

Abstract

Posner is one of the main contributors to what is known as “economic analysis of law.” In this entry, we restrict our presentation to a few controversial claims he made (efficiency, wealth-maximization, Hicks-Kaldor, judicial decision making).

Biography

Richard A. Posner was born in New York city January 11, 1939; he graduated from Harvard Law School and taught at Stanford University Law School and at the University of Chicago Law School; he is judge of the US Court of Appeals for the Seventh Circuit where he was appointed in 1981 and for which he was chief judge from 1993 to 2000.

General Presentation

The first point that could be noted is that Posner is one of the most important judges of all times in the USA. Christopher McCurdy and Ryan Thompson wrote in 2011, he “can arguably be called the most influential judge currently on the bench” (p. 50). Indeed, Posner is “a staple in legal casebooks . . . his name continues to show up in public discourse and peer judge interviews” (2011, p. 3). They cite a few figures that impressively witness of Posner’s influence: between 1998 and 2000, Judge Posner was cited 1,406 times (figure computed by Choi and Mitu Gulati 2004); between 1989 and 1991, he ranked third on the list of the “Top Twenty-Five Prestige Scores (Klein and Morrisroe 1999) and finally 118 Judge Posner opinions appeared in casebooks used in the 1999–2000 school year – ten times more than 90% of federal circuit judges. Yet, the American Bar Association – on a scale going from “exceptionally well qualified,” “well qualified,” “qualified,” to “not qualified” – gave him the “lowest possible ratings, ‘qualified/not qualified’” (Lott 2006). This is also impressive and reveals that, as important as he might be, Posner remains controversial in his judicial decision making.

Second, Posner is and has always been a public intellectual (Fleury and Marciano 2013). Writing for nonacademic audiences has never been secondary for Posner. It became more and more important these last 10 years, after 2004, when he launched the Becker-Posner blog (becker-posner-blog.com/), with economist and 1992 Nobel prize winner Gary Becker. What Posner posts on these blogs might seem a bit far-fetched

sometimes. It would have been useful and interesting to look at these writings in detail. For a lack of place, we left it aside.

Third, and obviously a major aspect of Posner’s work: his academic and scientific writing. Posner has been so prolific that it is impossible to summarize his ideas – one can find his list of publications on the website of the University of Chicago (see <http://www.law.uchicago.edu/faculty/posner-r>). One can nonetheless emphasize a few important ideas he put forward.

Innovative and Original Aspects

Economic Analysis of Law

In 1973 was published the first edition of *Economic Analysis of Law*. At the time, the book was reviewed as a contribution in *law and economics*: the book could “serve very well for a law and economics course” (Diamond 1974, p. 294) and indeed is a “coursebook in law-and-economics” (Krier 1974, p. 1697). At best, it was noted that “[w]ith the publication of Richard A. Posner’s economic analysis of law, that field of learning known as ‘Law and Economics’ [had] reached a stage of extended explicitness” (Leff 1974, p. 451). What was not viewed was that Posner had launched a new field. Economic analysis of law is not simply another name for from law and economics (see Harnay and Marciano 2009). By contrast with “law and economics” that defines economics by its subject matter, an economic analysis of law assumes that economics is a method, an approach or a set of tools that is used to understand nonmarket phenomena. It emerged in the early 1970s under the influence of Gary Becker (Fleury 2015). In this perspective, the law became an object that economists could analyze. Becker (1968), William Landes (1967, 1968, 1971) or Isaac Ehrlich (1970) proposed the first economic analyses of legal problems. Posner was not only the first one to name the field, with the title of his book, he was also the first to systematically adopt such an approach (see criticisms, in particular, in Backhaus 2017 and Malecka 2017).

Efficiency, as Wealth Maximization

One of the consequences of an economic analysis of law lies in the possibility of using the concept of efficiency to assess legal systems: rules, behaviors or judicial decisions are legitimate when or because they are efficient, which, to Posner, means when or because they maximize society's wealth.

Let us start by saying that Posner defines wealth in monetary terms exclusively, as

the value in dollars or dollar equivalents (...) of everything in society. It is measured by what people are willing to pay for something or, if they already own it, what they demand in money to give it up. The only kind of preference that counts in a system of wealth maximization is thus one that is backed up by money – in other words, that is registered in a market

(1979, p. 119). Or, “the sum of all tangible and intangible goods and services, weighted by prices of two sorts: offer prices (what people are willing to pay for goods they do not already own); and asking prices (what people demand to sell what they own)” (Posner 1995, p. 356).

Such definition of wealth is not as narrow as might appear at first sight. Indeed, Posner adopts a rather extended conception of markets. First, he does not restrict to explicit markets. But he considers implicit markets, in which services are sold that can be monetized by reference to substitute services sold in explicit markets. This enables Posner to use the wealth maximization criterion to assess the pecuniary value of a wide set of goods and services. Second, he also considers hypothetical markets, defined as those markets in which high transaction costs prevent individuals to transact with each other voluntarily and, therefore, efficient transactions to occur – for instance, individuals may be forced into involuntary transactions in the case of accidents, when a victim is obliged to transact with the injurer and the victim and the injurer cannot agree on a common price. Then, using a third party (e.g., a court) within a hypothetical market to determine the price of the transaction is a way to have the transaction occur actually and to achieve an efficient allocation of resources. Indeed, agents will consent to the accident-as-a-transaction as long as it is

wealth-maximizing, i.e., when it is less costly to let the accident occur than to prevent it. On the contrary, they will let the accident occur when it is wealth-enhancing. Then, transactions within hypothetical markets reconcile the possibility of involuntary transactions with the idea of individual consent that lies at the core of the wealth maximization criterion.

Indeed, Posner equates efficiency with wealth maximization. Thus, from this perspective, “[r]esources are efficiently allocated in a system of wealth maximization when there is no reallocation that would increase the wealth of society” (Posner 1980a, p. 243). That is, Posner remains in the standard maximizing framework of utilitarianism but substitutes wealth for “utility.”

Using wealth, instead of utility, as most economists usually do, allows Posner to solve the vexed problems of how to measure and to compare individual utilities. In a system based on “wealth maximization,” interpersonal comparison of wealth is possible, making it possible to compare the gains of one individual or a group of individuals to the losses incurred by another individual or group. Therefore, a transaction will be considered as legitimate and desirable when it increases the wealth of the society. Posner gives the following example:

I offer you \$5 for a bag of oranges, you accept, and the exchange is consummated. We can be confident that the wealth of the society has been increased. Before the transaction you had a bag of oranges worth less than \$5 to you and I had \$5; after the transaction you have \$5 and I have a bag of oranges worth more than \$5 to me. We are both richer, as measured by the money value we attach to the goods in question.

(1979, p. 120). The transaction is then legitimate and even desirable.

Another example is given by Posner: “[c]onsider an accident that inflicts a cost of \$100 with a probability of .01 and that would have cost \$3 to avoid. The accident is said to be a wealth-maximizing ‘transaction’ [...] because the expected accident cost (\$1) is less than the cost of avoidance” (1995, p. 358). Thus, clearly, what this accident costs to the society is less than what it would have costed to avoid it. An

individual who does not spend the \$3 to avoid a \$1 cost is not negligent. Conversely, if the cost of avoidance is lower than the accident cost, not only the accident is not wealth-maximizing but also an individual who would have not tried to avoid the accident would have been negligent. This is precisely why Posner also praised judge Learned Hand for his 1942 decision in a liability case: it was a wealth maximizing – and therefore efficient – decision (e.g., Posner 1972, p. 32, or 1999, p. 91).

Wealth and Capacity to Pay

Posner considers that wealth must be determined by using individuals' willingness to pay for a good rather than by its price. This is understandable for two reasons: first, on implicit and hypothetical markets, there are no prices and therefore the only way to value a transaction is to know what individuals would like to pay for a good; and second, the real value of a good for an individual is not represented by the price but by his or her willingness to pay. Wealth relates to consumers' surplus.

But then, one must also note that individuals may not only value a good they desire. They should be able to pay for it. Posner meant capacity to pay as a means to determine wealth:

a desire not backed by ability to pay has no standing—such a desire is neither an offer price nor an asking price. I may desperately desire a BMW, but if I am unwilling or unable to pay its purchase price, society's wealth would not be increased by transferring the BMW from its present owner to me. (1995, p. 357)

or,

that wanting something very much, but not being able to pay more for it than its owner or competing demanders, does not establish a claim to a good in a system of wealth maximization, although it might do so in a system of utility maximization. Wealth maximization thus excludes claims based on pure desire-claims not backed up by willingness (implying ability) to pay. (1980a, p. 243)

One would say that for a criterion that Posner also wanted to be “ethical” – he “argued that “wealth maximization” provides an ethically attractive norm for social and political choices, such as those made by courts asked to determine whether

negligence or strict liability should be the rule for deciding whether an injurer must compensate his victim” (1985, p. 85) – grounding “wealth” on individual's “capacity to pay” is problematic. Posner replied mainly by saying that one should distinguish efficiency from justice and the allocation from the distribution of resources. If a rule, a legal decision or a policy increases and maximizes wealth, then it directly benefits to certain individuals and not to others. Nothing prevents the use of redistributive policy to compensate the effects of such a wealth-increasing rule, decision, or policy.

This relates to another and quite important aspect of Posner's conception of wealth maximization: the Kaldor-Hicks criterion.

Kaldor-Hicks and Wealth Maximization

In economics, efficiency is measured in terms of Pareto optimality. However, Posner insisted that “Pareto superiority is not a necessary condition to be wealth maximizing” (Posner 1995, p. 357). Posner distinguished wealth from utility maximization à la Pareto. To him, a transaction, decision, or policy may be “wealth maximizing even if the victim is *not* compensated” (Posner 1995, p. 358; emphasis added). Precisely, to know if an allocation of resources is efficient without the Pareto criterion, which implies effective compensation, one may use the Kaldor-Hicks test, which rests on potential compensation. In other words, effective compensation is not required to characterize a move from one situation to another one: “[u]nder the Kaldor-Hicks definition of efficiency, which is also widely used by economists, a reallocation of resources is efficient if it enables the gainers to compensate the losers, whether or not they actually do so. This is equivalent to wealth maximization” (Posner 1980a, p. 244). Or, to put it in the more figurative terms Posner himself uses, an efficient decision in the Kaldor-Hicks sense consists in “making the pie larger without worrying about how the relative size of the slices changes” (2000, p. 1155).

Interestingly, this latter formulation reveals one important feature of Kaldor-Hicks efficiency and, therefore, of Posner's wealth maximization criterion: the exclusion of distributional issues and “normative considerations of distributive justice”

as the Kaldor-Hicks criterion “treats a dollar as worth the same to everyone.” (2000, p. 1154). However:

to the extent that distributive justice can be shown to be the proper business of some other branch of government or policy instrument (for example, redistributive taxation and spending) and that ignoring distributive considerations in the particular domain of decision making that is under consideration will not have systematic and substantive distributive consequences, it is possible to set distributive considerations to one side and use the Kaldor-Hicks approach with a good conscience. This assumes, as I have said, that efficiency in the Kaldor-Hicks sense . . . is a social value. (Posner 2000, pp. 1154–1155)

From that perspective, Posner adds, “efficiency in the Kaldor-Hicks sense is accepted as a social value, albeit not the only social value.” (Posner 2000, p. 1154). In addition, “even if Kaldor-Hicks efficiency has no social value”, it is “a convenient instrument” (Posner 2000, p. 1156) that can be used to decide whether or not one should make a decision. This is where Posner links the “Kaldor-Hicks concept of efficiency” to cost-benefit analysis: decisions can be made, rules modified, policy measures taken by comparing costs and benefits without the winners being obliged to compensate the losers. Then, if the benefits are greater than the costs, wealth is maximized; on the contrary, if costs exceed benefits, wealth is not maximized. Thus, the legitimacy of CBA comes from the use of a Kaldor-Hicks definition of efficiency. Reciprocally, Posner’s defense of CBA is also a defense of the Kaldor-Hicks principle.

Common Law and Efficiency

A major positive claim in the law and economics literature that was first formulated by Posner is that the common law is efficient. Indeed, the development of common law is mainly driven by judicial decisions issued in response to the needs of the society through cases. When facing new cases for which no precedent is available, judges make decisions relying on the economic efficiency criterion, defined as wealth maximization or Kaldor-Hicks efficiency. Thus, they are assumed to have a preference for efficiency over other moral values (such as income redistribution)

and to share that definition of efficiency as a desirable social goal with the society. Further, even if they prefer other values, they issue decisions promoting efficiency because the limitations of the judicial process constrain them in their ability to pursue other objectives. In particular, unlike legislators, they are poorly equipped with tools allowing them to engage in effective wealth redistribution or other unattainable values (see for instance Posner 1973, 1979, 2010). As a consequence, judges having internalized efficiency as a socially desirable goal, even unconsciously, adopt an economic logic when they make their decisions. Indeed,

[T]he character of common law litigation forces a confrontation with economic issues. The typical common law case involves a dispute between two parties over which one should bear a loss. In searching for a reasonably objective and impartial standard, as the traditions of the bench require him to do, the judge can hardly fail to consider whether the loss was the product of wasteful, uneconomical resource use. In a culture of scarcity, this is an urgent, an inescapable question. And at least an approximation to the answer is in most cases reasonably accessible to intuition and common sense. (Posner 1973, p. 99)

Parties to litigation consent to efficient decisions made by courts because their self-interest is promoted by supporting such decisions. Namely, “by doing so they increase the wealth of the society; they will get a share of that increased wealth; and there is no alternative norm that would yield a larger share” (Posner 1980b, p. 505). Furthermore, independent judges are insulated from interest group pressures and personal factors (Posner 1993) and can therefore promote social efficiency.

Resting on the examination of particular common law fields, much of Posner’s works are forceful attempts to determine what legal rules would be efficient and to examine how they correspond to the legal rules that exist. Along this line, he analyzes various fields of common law, including contract law, liability rules, property law, criminal law, family law, and sex law, using the lens of economic efficiency. Then, common law appears to differ from a collection of multiple and conflicting precedents whose coherence may at

first sight be uneasy to grasp. But it may rather be best understood as shaped by an economic – albeit most of the time implicit – economic logic underlying all judicial decisions and intending to maximize social wealth. Posner’s theory of the efficiency of common law helps thus rationalize common law within a single – economic – framework. In his own words (Posner 2011, pp. 315–316),

economics is the deep structure of the common law, and the doctrines of that law are the surface structure. The doctrines, understood in economic terms, form a coherent system for inducing people to behave efficiently, not only in explicit markets but across the whole range of social interactions.

Posner’s claim that the common law is efficient has fueled an important literature, either criticizing or agreeing with him. One of the most debated issues deals with the mechanisms likely to explain the evolution of law towards efficiency. A substantial body of literature has raised doubts about the existence of such mechanisms, for various reasons. First, the judicial preference for efficiency over other moral values and preferences (for leisure, reputation) has been a matter of considerable debate, whereas the apparent disinterest of judges in efficiency, at least as expressed in common-law court opinions, has been emphasized. Thus, in response to Posner’s seminal analysis, various demand-side models have been developed, calling attention to forces other than judicial preferences in explaining the law and suggesting that selective litigation of rules by parties may actually drive legal evolution and help promote efficient legal common law rules, regardless of judicial preferences, as inefficient rules may be challenged before courts and therefore overturned more often than efficient ones (see for instance Goodman 1978; Landes and Posner 1979; Priest 1977; Rubin 1977). Also in response to Posner’s theory of the evolution of common law, other works have cast doubt on the very fact that common law is efficient. Some authors point out that common law adjudication may rather lead to cycles of efficiency and inefficiency (Cooter and Kornhauser 1980). Others argue that the excessive amount of information needed for judges to decide cases may prevent them from

making efficient decisions (Aranson 1992; Rizzo 1980). It has also been argued that common law may lead to inefficient lock-in and path-dependency when it preserves obsolescent rules. Furthermore, Tullock (1980) has claimed that the English common law adjudication is less efficient than legislation – public choice critics mainly focusing on the idea that judicial processes are subject to the same sorts of interest-group pressures as are legislatures. More recently, the legal origins literature has revived the debates on the common law efficiency through its attempts to demonstrate the superior economic performance of common-law legal systems over other systems.

Judges (Judicial Preferences and Behavior)

Posner devoted a lot of work analyzing Judges and judicial behavior. It was one of the first areas that he viewed as important when he started to use economics to analyze the law. In 1971, he thus wrote that judges seem to display a certain propensity towards efficiency – they “are guided by concern with economic efficiency” (1971, p. 223) and “think in economic terms” (1971, p. 224). Or, in 1973, he insisted that one can “*assume* that judges make their decision in accordance with the criterion of efficiency” (1973, p. 325; emphasis added). What was important to Posner was to explain the efficiency of the Common Law. To be more precise, there were two versions of this theory. First, the positive version holds that rational judges having a preference for efficiency do actually issue decisions that maximize social wealth; hence, common law tends towards efficiency. Second, the normative view argues that judicial decisions should help common law to evolve towards efficiency, as rational judges should make their decisions with the wealth maximizing criterion (Posner 1980a).

Eventually, Posner criticized the traditional and idealized view on judicial behavior according to which public interest may be a judicial goal – assuming this is actually the case would amount to acknowledging that judges do not behave as ordinary human beings. To him, there is no reason to argue that judges are different from other individuals. Hence, it can be assumed that they are self-

interested utility maximizers – they maximize “the same thing as everybody else does” (1993). Their utility function may contain both monetary and nonmonetary arguments, such as leisure, popularity, prestige, and reputation. Judicial decisions may also have some pure consumption value for judges who may therefore derive some kind of positive utility from their decisions close to that derived by “artists or craftsmen who value aesthetic excellence in their field” (Posner 2008).

One of the consequences of this view is that judges may not follow the precedent and may be led to innovate. This means that this is consistent with the idea that judges create the law, that they acting as *interstitial legislators* and significant policy-makers.

Over time, Posner himself has also continued documenting the key role played by judges from both a theoretical and empirical standpoint, regularly publishing contributions on adjudication and judicial behavior – the room continuously dedicated to that issue in the successive editions of his textbook *Economic Analysis of Law*, as well as his most recent publications (2008, or 2013 with Epstein and Landes), obviously express his continuing interest for the topic.

Legacy

It is impossible to summarize Posner’s legacy. His impact on economic analyses of law is huge. It is probably not exaggerate to claim that all contributors to law and economics/economic analysis of law are in one way or another “Posnerians”. Either because they agree or because they disagree with him. Posner has radically transformed law and economics and also probably the legal system.

Power Indices

Dennis Leech

University of Warwick, Coventry, UK

Abstract

Many voting bodies are constituted on a principle of accountability whereby a member's influence is intended to be a reflection of a measure of size such as financial contribution or population. Examples include the joint stock company, the US Electoral College, the IMF executive and the EU council of ministers.

Power indices are a tool for addressing the (often ignored) problem inherent in this: that the constitution defines the voting rules and not the effective voting powers they imply. Indices due to Penrose-Banzhaf and Shapley-Shubik are often used. That they ignore preferences is often cited as a limitation with regard to positivistic analysis of existing constitutions but an advantage when they are used to address the normative problem of designing voting rules. Power indices can reveal hidden properties of voting rules that are not obvious at a superficial level. The issue of how to construct behavioral power indices that do take account of preferences remains an important research dimension. Power indices can also help us understand multi-tiered governance structures such as federal constitutions or corporate networks, an area where there is need for further research.

Power Indices

Many decision-making bodies are designed with voting rules that assign different voting powers to different participants. Examples include intergovernmental organizations such as the United Nations security council, the Bretton Woods institutions, the Council of Ministers of the European Union, and so on. Many are formally constituted to embody a principle of accountability whereby a member's influence through voting is intended to

be a reflection of financial contribution. An example is the joint stock company whereby shareholders' voting powers are directly proportional to the number of shares they own.

Power indices (more properly perhaps known as voting power indices because power is a much broader concept than is simply defined by formal voting rules) are a tool for addressing the important problem inherent in this: that the constitution defines the voting rules and not the voting powers they imply. For example a shareholder who owns 40% of a company's voting shares could have nearly 100% of the voting power in the sense of the ability to determine a decision taken by voting if the other 60% of shares are widely held. But on the other hand, it could be worth less than 40% of the decision-making power if there are other large bloc shareholders. This problem is rarely acknowledged by policy makers and even more rarely addressed. The best reference on voting power is Felsenthal and Machover (1998).

Power indices are quantitative measures of the influence of each voter in terms of the voter's ability to affect the outcome whenever a hypothetical vote is taken. The basis of the definition of the index is an examination of each possible "yes/no" vote that is theoretically possible. A voter has voting power whenever he (or she or it if the voter is an institution) can change the outcome of a vote from "no" to "yes" by changing the way he casts his vote. The power index for any voter is then the proportion of voting outcomes – taking into account all the possible ways all the voters can cast their votes – for which this is possible.

A real-world example of why this approach is important is provided by the history of the original European Economic Community when it was founded in 1958. The council of ministers adopted a system of qualified majority voting with weighted voting whereby the three largest countries (France, Italy, and West Germany) all had four votes each, the smaller countries (Belgium and Netherlands) two, and tiny Luxembourg one. This was intended to ensure that Luxembourg got due recognition as a sovereign state beyond what its tiny population size might warrant if representation was to be strictly proportional to population. So the intention of the framers of the

constitution of the EEC was that voting weights be less than proportional to population so that the larger countries would be underrepresented relative to their populations. However an examination of the voting rule against possible voting outcomes indicates that this assumption is far from the truth. The voting rule was that a qualified majority decision required a threshold of 12 or more weighted votes to pass. Therefore, in order for the vote of Luxembourg to be able to make a difference, that is, for Luxembourg have voting power, there would have to be 11 "yes" votes from the other countries. But the constitution guaranteed that was impossible. So Luxembourg had zero voting power although it had almost 6% of the voting weight. The subject of the design of the system of qualified majority voting for the council of ministers, particularly in the Nice and Lisbon treaties, has given rise to a substantial literature on voting power indices.

All this is straightforward, but turning the idea of measuring voting power into a practical voting power index is not. How voting outcomes should be counted – whether orderings or divisions of voters – is not obvious, and this has given rise to different indices that give different results in general. There are two so-called classical indices, often referred to as the Penrose-Banzhaf index (PBI) and the Shapley-Shubik index (SSI) (though nomenclature varies between authors). The SSI is based on the idea that voting outcomes are essentially orderings of voters; each ordering counts equally as a different possible outcome of the voting rules. Each voter has power to the extent they can be the pivot or swing voter able to change the decision from "no" to "yes." On the other hand, the PBI treats each possible division of voters into two groups voting "for" and "against" a decision. A power index is then defined for each voter as the proportion of outcomes for which that voter is the pivot or swing (Banzhaf 1964; Shapley and Shubik 1954; Penrose 1946).

These definitions lend themselves to interpretation as probabilities, each voting outcome being deemed to occur randomly with equal probability, and are often expressed in such terms. This interpretation has led to criticism by scholars who

object to the idea of random voting as a description of real-world behavior. However this probabilistic interpretation is not essential, and a simple interpretation in terms of relative frequencies of outcomes avoids the need to assume anything about behavior. Nevertheless, because direct computation of power indices from basic definitions requires consideration of all outcomes, this can be difficult when the number of voters is large; then algorithms based formally on probability theory are useful (Leech 2003).

Much of the literature fails to get to grips with the issue of which of the two classical power indices is better as a measure of voting power. There tends to be a preponderance in applied work for the PBI, probably because the idea of an outcome of a vote as a division has more intuitive appeal than an ordering, but many studies report the two indices side by side, leaving it to the reader to decide between them. The case against the SSI was first made by Coleman (1971) who argued strongly against the SSI on the basis that treating all orderings of voters is theoretically implausible and the weighting the formula requires is not justified. See Leech (2002), which also showed that results from applying the SSI to British company shareholdings gave results at variance with empirical evidence about company control.

A second major issue, besides the choice of which coalition model to use, relates to what sort of analysis is being done using the voting power indices. Is a voting power index meant to tell us about how voters actually behave in reality or about nothing more than theoretical possibilities? The failure of many writers to recognize this point has led to a lot of – often strongly expressed – discussion. In fact it is important to distinguish between two types of analysis for which power indices are useful: normative and positive.

Normative analysis is concerned with the design of voting rules. It is essential that this is done “a priori” without regard to the preferences or likely voting behavior of the voters. The voting rule is seen as being designed behind a Rawlsian veil of ignorance that attributes equal importance to all voting outcomes that can theoretically occur. It would clearly be morally wrong, for instance,

when considering the enlargement of a voting entity such as the European Union, to allocate votes to a new member on the basis of its likely voting behavior: to give it different weighted votes as to whether it was likely to support or oppose a particular grouping. Nothing other than an objective measure such as population would be reasonable as a basis for choosing its voting weight. Therefore for this normative analysis, it would be wrong to take account of preferences (Braham and Holler 2005).

This point has been ignored by positivist writers who have tended to be more interested in the behavior of voters with respect to a *given* voting rule than the *choice* of voting rule. From a positivist point of view, a priori or “constitutional” power indices, the PBI and SSI, have been criticized for not taking account of preferences which would assign different probabilities to different outcomes. In the EU council, for example, a positivist description of voting behavior would give a higher probability to outcomes where France and Germany vote on the same side than where the UK and France or Germany are in agreement. The PBI and SSI are clearly limited measures of voting power from this point of view.

Voter	Weight	BPI	Weight	BPI	Weight	BPI
1	9	0.0	9	5.0	9	10.0
2	17	20.0	16	15.0	9	10.0
3	17	20.0	17	18.3	17	16.7
4	18	20.0	17	18.3	18	16.7
5	19	20.0	17	18.3	19	16.7
6	20	20.0	24	25.0	27	30.0

Percentages. Threshold 51. Normalized BPI. Computations using algorithm at [Leech and Leech](#)

There is a need for much more work on developing “a posteriori” or “behavioral” power indices which do take account of preferences and are able to give an empirical account of the distribution of voting power.

One aspect of the normative use of power indices is in enabling the discovery of hidden properties of constitutional designs. In the EEC example above, it was fairly easy to spot that there was a voter with positive weight but zero power. But more complicated voting rules require voting

power analysis. The table below shows some possibilities that can occur with six voters. Fairly innocuous-looking changes to the voting weights assigned to other voters can make a profound difference to the share of voting power enjoyed by the voter number 1 with 9% of the votes, from 0% to 10%. This illustrates a particularly useful application of voting power analysis in being able to find that a voter with positive weight has in fact zero power. Such a voter is known in the literature as dummy. This feature of voting power analysis is especially useful because it is independent both of the index used and also whether or not preferences are taken into account.

The main open research question is the choice of which of the two so-called “classical” power indices, BPI or SSI, is better. So far there is no consensus on the best index to measure voting power. Some scholars prefer the mathematical rigor of the SSI, while others argue that the assumptions underlying the BPI contain more realism. There is also the challenge of developing behavioral power indices.

Much discussion recently has centered on the properties of voting power indices in *large* voting bodies, that is, when the number of voters is large in some sense. It has been argued that there is a general asymptotic tendency, as the number of voters increases without limit, for relative voting powers to become proportional to relative voting weight. Lindner and Machover (2004) have come up with sufficient conditions for this, which they called “Penrose’s limit theorem.” Leech (2013) however has shown that this is a special case, and there is no tendency toward proportionality of voting power indices and voting weight in general.

An important extension of the voting power indices method as an analytical tool is to multi-level voting rules such as voting power in federal systems (e.g., the US electoral college, see Miller (2013)), company groups with complex ownership structures Crama and Leruth (2007), and many other applications.

Voting power remains an active research field. Two recently published edited volumes containing applications are Holler and Nurmi (2013) and Fara et al. (2014).

Preferential Tariffs

Laura Huici Sancho

Department of International Law and Economics,
University of Barcelona, Barcelona, Spain

Abstract

Tariff preferences refer to measures that involve tariff reductions which benefit certain goods originating in certain countries. Historically tariff preferences were agreed on a reciprocal basis to recognize special relations between states. The multilateralization of

trade implied the generalization of preferences, which become an instrument for development cooperation. Tariff preferences might be accorded, unilaterally or through regional agreement schemes, to developing countries. However the progressive reduction of tariffs in international trade limits the role of tariff preferences as an instrument to agree a special treatment to certain kind of countries. Besides the increasing diversity of states requires of flexible instruments that allow special and differential treatment to better adapt to development, financial and trade needs.

This unequal treatment, which is characteristic of preferences, has turned them into a major instrument of development cooperation, and they are thus used for building relations between developed and developing countries. Nevertheless, the increasing use of the MFN in trade agreements, the multilateralization of such with the signing of GATT, the progress made in liberalizing trade as a result of successive rounds of trade negotiations, the creation of the WTO, and the expansion of its Member States are factors that have led to a declining role of tariff *preferences* as tariff reductions have gradually become more widespread.

Synonyms

Commercial benefits; Commercial concessions; Tariff benefits; Tariff concessions

Definition

Preferences are concessions which involve special treatment in trade relations between two or more countries, economic integration organizations, or regional groupings. Generally speaking, a benefit stemming from a treaty that is not extended to all states, whether they are party to it or not, may be regarded as a *preference*. However, in international economic law, the term *preferences* is used more specifically to refer to measures that involve tariff reductions which benefit only goods originating in certain countries. With this meaning, preferences aim to liberalize trade relations, since they involve reductions or even the elimination of tariffs. Yet they upset the principle of no discrimination because, by definition, they do not apply equally to all states. So being contrary to the Most Favoured Nation Clause (MFN), in the GATT/WTO system, preferences can find justification in article XXIV, the Enabling Clause, or requesting a specific waiver (GATT article XXV:5 – WTO article IX:3).

Preferences may be reserved only for certain types of products originating in certain countries; they may be limited qualitatively to certain goods and/or be subjected to quantitative restrictions.

An Historical Overview of Preferences: An Evolving Institution

The notion of preferences may be defined through their historical evolution with emphasis placed on their main features and most controversial points. With this objective in mind, four stages may be distinguished: first, preferences are incorporated into trade agreements on a reciprocal basis and respond primarily to factors concerning particular links between states; second, as part of the multilateralization of trade relations, these tend to favor the generalization of preferences limited to relations between developed and developing countries, thus eliminating reciprocity; third, preferences tend to place more conditions on compliance with certain requirements, particularly environmental and labor protection; and fourth, a crisis of the unilateral tariff preferences model has arisen, raising doubts concerning their interest and continuity in the near future, while regional preferential trade agreements are growing and new models of preferential treatment have appeared.

Reciprocal and Special Preferences

Traditionally, the establishment of a *preferential* relationship between parties was the subject of trade agreements in which states made mutual concessions. Often, the establishment of these preferences responded to the existence of cultural, historical, or geographical ties among the affected countries which sought to encourage and enhance their trade relations with a reciprocal recognition

of preferences. It should be noted that preferential and reciprocal tariff treatment among members is the basis of the free trade areas and customs unions which constitute, in this sense, specific examples of special preferential arrangements.

Granting preferential tariffs became common in relations between the metropolis and its colonies once these had become independent states. One example is the *imperial preferences* that were first established by the United Kingdom among its colonies and later continued with the Commonwealth countries. Despite initial opposition, “at the Imperial Economic Conference of 1932 in Ottawa the United Kingdom finally accepted the extension of imperial preference throughout the Empire. Eleven bilateral agreements were signed and the whole system of Empire preferences was augmented and co-ordinated” (Clute and Wilson 1958, p. 464). As regards the terms of these agreements, “the imperial preference system is a maze of fiscal arrangements, by which each participant admits into its markets certain exports of the others at lower tariff rates than are imposed upon the same products when originating elsewhere” (Feis 1945–1946, p. 663). This was a unique exclusive system of special preferences for Commonwealth members. If a member of the Commonwealth ever offered the same preferential treatment to a nonmember state, it would have to obtain a *waiver* that would allow it to do so. This unequal treatment raised tensions in relations with nonparticipating countries, in particular the USA, which led the multilateralization process of trade relations on the basis of MFN. At the signing of the GATT in 1947, the compatibility of imperial preferences with the MFN clause was recognized but limiting their future expansion (Clute and Wilson 1958, p. 467).

Another example of preferences granted to former colonies are Association Agreements signed by the European Economic Community and the African, Caribbean and Pacific Countries (ACP). The need to provide a special relationship with states that had formerly been colonies of a Member State is explicitly recognized in the Treaty of Rome signed in 1957, which established the European Economic Community (EEC). Based on this, the EEC granted preferences to several

countries that were mainly former French and Belgian colonies. In the Yaoundé Convention, held in 1963, the EEC implemented a progressive reduction of tariffs on products originating in the 18 African and Malagasy States which participated in this Convention (Article 2 of the Convention), and tariffs were completely eliminated for certain tropical products. In return, these countries undertook to eliminate any differential treatment between the six Member States of the EEC and to reduce tariffs on their products, although they did allow some flexibility at this point to protect their domestic industry (Article 3 of the Convention). In 1969, a second Yaoundé Convention was signed extending these reciprocal preferences and three more African countries were included.

The situation evolved with the signing of the Lomé Convention in 1975. The UK's entry into the EEC led to this Convention being expanded to the Association of Caribbean and Pacific States, reaching a total of 46 members. The United Kingdom was forced to leave its Commonwealth model behind and adapt to the EEC Association model. However, countries such as Canada, Australia, New Zealand, and India were not included in the statute of association and were forced to seek other means of cooperation such as trade agreements adopted on the basis of Article 113 of the Treaty of Rome. As regards the system of preferences, the Lomé I Convention signed in 1975 preserved the tariff preferences of the Yaoundé Conventions but reciprocity was reduced. Products from the ACP States benefited from a reduction or elimination of tariffs in the EEC (articles 2 and 3 of the Convention), while European products only received the MFN treatment among the Associated States (article 7 of the Convention). These general features of the system of preferences were continued in the successive Lomé II Convention signed in 1979 and Lomé III Convention signed in 1984. Even after the EEC's Generalized System of Preferences (GSP) was implemented, the Associated States benefited from better preferences than other developing countries (Grilli 1994, p. 148).

Along with the agreements with the ACP countries, the EEC also signed trade and cooperation

agreements with other states. This group included, among others, agreements with the Maghreb, Masreq, and other countries from around the Mediterranean together with several Asian and Latin American countries, which also recognized a system of preferences for them, not as high as the ACP, but still prioritized them (Grilli 1994, p. 151). In these agreements, preferences were not subject to providing direct reciprocity but were significantly limited to protect the EEC's *sensitive* products or sectors.

The nonreciprocity of preferences as well as the abolition of special regimes or reverse preferences and their replacement by a GSP was repeatedly called for by several states at the Second United Nations Conference on Trade and Development (UNCTAD) held in New Delhi in 1968 (UNCTAD doc. TD/97, Vol. I, 1968). The USA demanded that states receiving these preferences should give them up if they wished to receive preferential treatment from them. Opposing this, the EEC, the United Kingdom, and the states benefitting from these special preferences insisted that the generalization of preferences should not harm them. However, all participants agreed to eliminate the need for reciprocity and turn preferences into an instrument for development cooperation which would benefit all developing countries and serve to increase exports and aid access to international trade relations.

The Generalization of Preferences

The signing of the GATT Agreement in 1947 established the application of the MFN clause in trade relations, thus prioritizing the principle of nondiscrimination between the participating states. Although the GATT was not unaware of the existence of special regimes which, as pointed out in the previous section, prioritized relations between some participating states, these were found to be compatible with the system. Along with this, following World War II, the idea spread that aid should be given by developed countries to developing countries. The United Nations Charter linked the need for cooperation among states to reduce economic and social differences in order to ensure international peace and security (Chapter IX of the UN Charter).

It was the developing countries that would eventually introduce into the debate the need to regulate international trade to address their specific needs. As early as 1961, India called for the establishment of general tariff preferences in the GATT. In a joint declaration, titled Appendix to Resolution 1897 (XVIII) of the United Nations General Assembly, 11 November 1963, several developing countries stated that “international trade could become a more powerful instrument and vehicle of economic development not only through the expansion of the traditional exports of the developing countries, but also through the development of markets for their new products.” This was the aim of the First UNCTAD Conference held in 1964, which supported the idea of establishing a GSP to favor developing countries in order to increase and diversify their commercial relations (Final act, doc. E/CONF/46/139, 1964).

In the Charter of Algiers, approved at the Ministerial Meeting of the Group of 77 on 24 October 1967, urgent immediate measures were called for to encourage trade with developing countries and a series of principles was also passed for a general system of tariff preferences that “should provide for unrestricted and duty-free access to the markets of all the developed countries for all manufactures and semi-manufactures from all developing countries.” This model was debated in the Second UNCTAD Conference which ended with the unanimous adoption of Resolution 21 (II), *on preferential or free entry of exports of manufactures and semimanufactures of developing countries to developed countries*, whereby an acceptable mutual and Generalized System of Preferences was agreed and implemented, with no reciprocity or discrimination which would be advantageous for developing countries. In sum, UNCTAD adopted the idea of a “non-discriminatory” system of discrimination in favor of all less developed countries” (Metzger 1967, p. 770). However, the developed countries’ position on this issue varied widely.

Not all developed countries were willing to grant a GSP with the same conditions and features. As pointed out in the document addressed to UNCTAD by the OECD in 1969, “each donor country nonetheless reserves the right of taking

action appropriate to its own possibilities and taking account of certain features of its particular circumstances” (doc. OECD C(69)142). Thus developed countries believed that a GSP must be voluntary. Furthermore, donor countries failed to agree on the possibility of establishing quantitative restrictions, identifying beneficiary states, or limiting the types of products that may benefit from preferences. So, far from achieving the establishment of a single GSP for all developing countries, a proliferation of GSP arose.

The GSP approved by Australia in 1966 provided “non-reciprocal preferences on selected manufactures and semi-manufactures from developing countries up to the levels of specified quotas for each commodity.” The scheme was aimed at less developed countries which could seek to benefit from certain preferential annual import quotas for certain products, unless they were already competitive by themselves (GATT Doc L/2627, April 4, 1966 on Australia). This first scheme which was adopted for 1 year has since continued to be extended and modified, successively amending fees and/or scope of preferences.

In 1971, the EEC approved its first GSP providing tariff preferences for developing countries. The preferences were limited to a series of regulations that established criteria to identify which products were regarded as originating in developing countries and therefore most likely to benefit from the preferences. It was a complex and seemingly rigid system which aimed to recognize substantial advantages for transformed agricultural products and semimanufactured or manufactured goods from developing countries while preserving the interests of the industries of the Member States and Associated States (Hoffmann, 1971 p. 650). The preferences were highly limited in the case of agricultural products, subject to quantitative restrictions, and mainly aimed at the Group of 77 Member States and Hong Kong. The EEC would also gradually modify this first scheme and has renewed its GSP ever since.

Throughout 1971 and early 1972, other developed countries implemented their respective GSP. However, just like the previous two, all included safeguard mechanisms and largely excluded products that might be of interest for

developing countries, which significantly limited, at least in the short term, the effects of GSP on exports (Hoffmann 1971, p. 660). However, differential treatment included in the GSP contradicted the obligations stemming from the MFN under Article I of the GATT, and so it was necessary to obtain a waiver to implement it and provide continuity. From this perspective, the need soon arose for a provision that would generally uphold this special and differential treatment received by developing countries.

The continuity of differential treatment and tariff preferences for developing countries was considered from the outset of the Tokyo Round negotiations. The Enabling Clause was part of the resolutions adopted at the end of the negotiations in 1979 and aimed to accommodate differential and more favorable treatment for developing countries. This clause was based on the compatibility of “preferential tariff treatment accorded by developed contracting parties to products originating in developing countries in accordance with the Generalized System of Preferences” (Article 2 (a), GATT doc. L/4903). The problem was how to interpret the terms of the Enabling Clause in relation to the MFN clause and particularly, whether it allowed the interpretation made by developed countries as regards distinguishing developing countries.

There is no absolute answer to this question. For one, neither the GATT nor the WTO provides a definition or list of developing countries, while this group is becoming increasingly more diverse. Above and beyond the group of least developing countries (LDC) that are identified by the UN, or the orientations that may arise from the World Bank’s classifications or the human development index, it is states that grant preferences that unilaterally decide which they regard as developing countries. Additionally, the Enabling Clause states that “any differential and more favorable treatment provided under this clause shall (...) be designed and, if necessary, modified, to respond positively to the development, financial and trade needs of developing countries” (article 3 (c) GATT doc. L4903). These terms may be interpreted as providing different treatment according to different needs which may be

consistent with the system. The different interpretations regarding this were highlighted by the WTO's Dispute Settlement Body (DSB) in the case lodged by India against the EU due to its GSP in 2002. As will be seen in the following section, India questioned whether the special arrangement to combat drug production and trafficking should not be open to any developing country which might benefit from the European Union's GSP. The Panel's report concluded that "the term non-discriminatory (...) requires that identical tariff preferences under the GSP be provided to all Developing Countries without differentiation" (Doc. WT/DS246/R, above no. 6). Later, the Appellate Body (AB) overruled this opinion stating that "the term 'developing countries' in paragraph 2(a) should not be read to mean 'all' Developing Countries" (WTO doc. WT/DS246/AB/R, above no 25). Differential treatment might be acceptable as it would be defined according to "financial and trade needs of developing countries."

In short, although GSP have indeed led to a generalization of preferences for the beneficiary states, they have not done so in an absolute sense, but rather, this has meant that potentially any state regarded as a developing country by countries granting the preferences can benefit from the same if it proves it meets the requirements of such a scheme. The Decision on Implementation-Related Issues and Concerns adopted in 2001 as part of the Doha Round states that "preferences should be non-discriminatory" but are not specifically required (WTO doc. WT/MIN (01)/17, 41 LL.M. 757 (2002)). This relative notion of a generalized treatment is exacerbated when features of conditions unrelated to trade are added to the granting of preferences.

The Conditionality of Preferences: A New Way to Reverse Preferences?

The Enabling Clause specifies that "the developed countries do not expect reciprocity for commitments made by them in trade negotiations to reduce or remove tariffs and other barriers to the trade of developing countries, i.e., developed countries do not expect the developing countries, in the course of trade negotiations, to make

contributions which are inconsistent with their individual development, financial and trade needs" (article 5, GATT doc. L/4903). This section consolidates the nonreciprocity of preferences in relations between developed and developing countries. However, once again the reference made to the "development, financial and trade needs of developing countries" opens up the gate used by developed countries to condition the preferences granted to developing countries.

In its preamble, the Lomé IV Convention signed between the European Community (EC) and the ACP countries in 1990 emphasized the close relationship between promoting and respecting human rights and environmental protection for developing states. The aim of the association is to promote sustainable development and does not depend solely or primarily on an increase in trade relations nor, particularly, exports of these countries. With the review of the Convention in 1995, aid to the Associated States was linked to fulfilling the objectives of respecting human rights and the principles of good governance since noncompliance may justify withdrawal of aid or preferential treatment. The Cotonou Agreement, after 2000, has maintained this link of association with the aim of sustainable development and good governance. The erosion of preferences as a result of the reduction of general tariffs prioritizes measures of positive cooperation by consolidating the requirements of preferential trade treatment on these other obligations which are regarded as intrinsic to the effective development of countries.

In the same vein, in the early 1990s, the EC would also establish additional special tariff preferences under its GSP for products originating in the Andean and Central American states with the aim of aiding the fight against drug production and trafficking. Combating the production and trafficking of drugs was seen to be essential for the development of these countries, and in this sense, the special scheme seemed justified. Special incentive arrangements were introduced to protect labor rights and the environment a few years later, in 1994 and 1996. Again the EC granted additional preferences to developing

countries for adopting and implementing, on a domestic level, international environmental standards for agriculture, the substance of the standards laid down by the ITTO relating to the sustainable management of forests and the International Labor Organization Conventions numbers 87 and 98 concerning the application of the principles of the right to organize and to bargain collectively, and number 138 concerning the minimum age for admission to employment. In these cases, protecting the environment and recognizing labor rights were presented as “special development, financial and trade needs of developing countries.”

In 2001, the Council Regulation 2501/2001, which approved the GSP scheme for the period 2002–2004, finally grouped into one single legislative instrument the provisions relative to the general preference scheme and four special regimes for least developed countries – the everything but arms initiative – to combat drug production and trafficking; for the protection of labor rights; and for the protection of the environment. The first two were aimed only at certain developing countries. This included the LDC, identified as such by the United Nations, whose particular situation is explicitly recognized in the Enabling Clause and the waiver agreed in 1999, renewed in 2009 (doc. WT/L/304, 1990 & WT/L/759, 2009). The regime to combat drug production and trafficking was only aimed at states which the EU included in their list of beneficiaries without giving objective criteria. However, the two other special arrangements are open to any developing country that already participates in the GSP and is shown to comply with the additional conditions imposed on them by such. According to the EU, all these special regimes respond to special development, financial and trade needs of developing countries, and are, therefore, based on the Enabling Clause.

Given this interpretation, India argued in its application to the WTO’s DSB that the special arrangement to combat drug production and trafficking was discriminatory because the list of beneficiary states was unilaterally set by the EU without providing any criteria which, objectively, has led to some developing countries and not

others to be included as beneficiaries of the EU’s GSP. As mentioned above, the panel and the AB disagreed on this point yet, although the AB found that differential treatment for developing countries is, in principle, compatible with the Enabling Clause (since it must adapt to the specific needs of each country), it concluded that the EU’s special drugs regime is contrary to it, as the criteria that led to defining the list of beneficiary states (WTO doc. WT/DS246/AB/R, above 25) were not justified. However, in this case no questions were raised over the conditionality of the preferences contained in special schemes, but how countries benefitting from the preferences in the special scheme were chosen, which meant these preferences would not be available to all developing countries that might have the same needs. In short, it is not discriminatory to provide differential treatment to a different situation, but it is if the situation is the same or very similar.

Following this decision, the EU revised its GSP and Regulation 980/2005 established the GSP plus, which included three regimes of preferences: a general arrangement, a special incentive arrangement for sustainable development and good governance, and a special arrangement for LDC (article 1 of the Regulation). Apart from the LDC scheme, the other special scheme addresses countries ratifying or undertaking to ratify the agreements specified in Annex III of the Regulation. This lists what the EU considers the major universal international treaties for the protection of human rights, labor rights, environmental protection, and those protecting principles of good governance. Countries that can prove they meet the conditions may request to benefit from additional preferences under the special regime and the European Commission must ensure they comply with the requirements. Regulations 732/2008 and 978/2012 maintain three distinct regimes, without ever questioning their compatibility with WTO rules. Against this, some authors argue that the choice of a closed list of international treaties, such as the sections in Annex III of the EU Regulation, is not flexible and cannot adapt to the needs and reality of each developing country (Bartels 2007, p. 884; Turksen 2009, p.965; Wardhaugh 2013, p 839).

USA's GSP shares the carrot-and-stick approach used by the EU and also establishes differences between developing countries submitted to complying with certain conditions or criteria. Instead of setting out special regimes as part of the GSP, the USA has established specific regional preference programs and has obtained waivers for the Caribbean Basin Economic Recovery Act, the Andean Trade Preference Act, and the African Growth and Opportunity Act. All these programs establish more benefits than the US GSP, but they are restricted to some specific countries and submitted to US foreign policy interests (Kennedy 2012). Besides the USA maintain their GSP. To identify the beneficiary developing countries in the GSP, the conditions are, for instance, that they may not be communist countries; they must respect labor rights and must wipe out child labor, cooperate in the fight against terrorism, respect intellectual property rights, and apply international arbitration decisions. These conditions are established and applied unilaterally and discretionally by the USA. For example, more than 20 years ago, the USA decided to reduce up to 50% the benefits accorded to Argentina through the GSP because they had estimated that national legislation had not granted enough protection to intellectual property rights (Lavopa and Dalle 2012).

Conditionality may seem like a form of reciprocity as it requires a certain action to be taken by developing countries to benefit from a preference (Kishore 2011, p. 895). Subjecting preferences to respecting certain human rights, protecting the environment or the democratic principles of government introduces issues as factors of development that are not directly related to trade. In the Doha Round, developing countries were able to keep these issues out of the negotiations. The unilateral basis which defined the GSP and other preferential trade relations has allowed developed countries to reintroduce them into the debate by conditioning the preferences. Indeed, it is hard to deny that these issues are key to the development of a country, but the way that these are presented seem to respond more to the needs of developed countries than developing countries.

Erosion of Preferences, but Not Their Disappearance

The impact of preferences on developing countries has differed depending on whether they have been channeled through special regional agreements, such as the Association Agreements between the EU and the ACP States or the US Caribbean Basin Initiative, or by establishing a GSP. Developing countries participating in regional preferential agreements enjoy a special and privileged status compared to the rest. The concessions under these agreements are larger, tariffs are reduced or even eliminated, and the product range is wider. On this point the GSP face three problems. First, they are also of a unilaterally voluntary nature which makes them respond more to considerations imposed by the donor states than the most urgent needs of the beneficiary countries. Second, they are open to a larger group of states and are therefore more diverse, and not every country can always benefit from the same levels of preferences. Third, implementing GSP preferences involves a difficult process which leads to an increase in costs, sometimes making it unattractive to the potential beneficiary. It is up to the developing countries to apply for these preferences and demonstrate that their products comply with the regulations of origin set out in GSP, which may involve additional costs and reduce the final benefit. From this perspective, many authors criticize the results achieved by the GSP.

The general reduction of tariffs in international trade has also progressively limited the role of tariff preferences as an instrument for development cooperation. The issue of preference erosion has been widely debated in by authors for years. In regional preferential agreements, this loss has been offset by other means of cooperation, such as financial or technical assistance. But the GSP are the result of a different logic and have also been stretched by the existence and proliferation of other preferential trade agreements which provide greater preferences than those general schemes and due to the loss of margin for preferential treatment as a result of successive negotiation rounds.

Furthermore, the temporary nature that characterizes the special and differential treatment for

developing countries in the WTO creates some uncertainty. It seeks to promote development so that once the goal is achieved *exceptions* to the principle of nondiscrimination and the MFN governing multilateral trade relations will become meaningless. This feeling of uncertainty is greater in the case of a strictly unilateral GSP. A GSP depends on the willingness of the states to establish such, and they may eventually decide not to continue it. However, it is worth noting that the main GSP still persist today. The EU, the USA, and Russia have renewed their GSP in 2013; Australia did so in 2012; and Japan in 2010. But, for example, the EU has severely reduced the list of beneficiary states excluding from 2015 those states that have been classified by the World Bank as upper-middle-income countries since 2011 (European Commission delegated Regulation 1421/2013). Ways remain to be explored that can empower the role of tariff preferences as tools for development. Agreements that facilitate the management of trade in goods subject to tariff preferences would represent a qualitative edge in response to an open, general, debate in the WTO (Bartels and Häberli 2010; Persson 2012).

Before concluding it should be recalled that a more general definition of the term “preference” means any treatment that is more beneficial for a state. Other agreements also provide preferences with this broader meaning that have been of great interest to the beneficiaries. Of special interest is the decision referring to preferential treatment to services and service suppliers of LDC, 2011, which allows members to grant “preferential treatment to services and service suppliers of Least Developed Countries without according the same treatment to like services and service suppliers of all other Members” (doc. WT/L/847). The terms of this document are quite similar to those of the Enabling Clause, because preferential treatment is justified in order to increase the participation of LDCs in trade in services, which are expected to become generalized preferences for all LDC, but of a unilateral nature from the perspective of the donor state, and set temporarily.

Nevertheless, there is an increasing diversity of states in different levels of social and economic development. Today it is difficult to maintain the division between developed and developing countries as clearly separate and stable groups in different areas of international cooperation (Pauwelyn 2013). This is reflected by developing countries acting less in common, which may weaken their ability to negotiate, but also that of developed countries, some of which face serious domestic problems with a much lower growth rate than in other so-called developing countries. A system based on a generalization of preferences does not adapt well to this reality than more than ever requires ample flexibility to adapt to the “development, financial and trade needs” of the beneficiary states.

Prisoner's Dilemma

Wolfgang Buchholz and Michael Eichenseer
University of Regensburg, Regensburg, Germany

Abstract

The Prisoner's Dilemma (PD) is probably the most famous two-person game in which a fundamental divergence between individual and collective rationalities arises: If the agents play noncooperatively, an equilibrium is achieved which, however, does not constitute the best available solution. Such a PD situation characterizes many situations of voluntary cooperation, e.g., the provision of the global public good climate protection. But in reality agents are – despite the predictions of the PD game – often willing to cooperate voluntarily to some degree which has been confirmed by experimental economics. Furthermore there are a lot of institutional devices which help overcome the cooperation dilemma in a PD situation.

The Standard Prisoner Story

The Prisoner's Dilemma (PD) is probably one of the most famous games analyzed in game theory. Its name refers to a rather artificial story conceived by the American mathematician Albert Tucker in order to convey the structure of the PD game to a broader public: Two prisoners – A(ndrea) and B(ritney) – who have jointly committed crimes are interrogated by the police separately without any chance of communicating with each other. Actually the police cannot take enough evidence to convict them of a serious crime (what the police clearly would like to do) but only of a smaller crime which would send both A and B to prison for 1 year. Without further provisions neither A nor B will have an incentive to tell the truth about the serious crime. Anticipating this discretion, the police offer a principal witness regulation: If one of the two prisoners betrays the other, she will be set free immediately while the thus convicted perpetrator will have to go to jail for 3 years. This regulation, however, only applies if just one of the two prisoners confesses and sends her accomplice to the doom. Otherwise, i.e., when both prisoners give evidence, both A and B will have to serve 2 years.

Even though this story has some drawbacks (e.g., as it is not obvious why in the case of a unilateral confession the betrayed prisoner should get a harder punishment), it highlights the cooperation dilemma that occurs in a PD situation: When acting in complete isolation from one another, the best each prisoner can do is to admit to a more serious crime – independent of what she expects her co-perpetrator to do. Such a behavior follows from a rational calculation which runs as follows: If my counterpart confesses, I will be imprisoned for 3 years if I remain silent but only for 2 years if I confess, too. Likewise, if the other one remains silent, my best strategy is again to confess because in this case I can benefit from the principal witness regulation and avoid staying in jail any longer.

In technical terms this means that in a PD, confessing is the dominant strategy for player A as well as for player B. Thus the game's outcome will be that each prisoner confesses and

goes to jail for 2 years. This, however, does not seem to be a satisfactory solution for either of them: If both remained silent instead, they could improve their situation since this would save each of them 1 year in prison. However, the problem is that the personal incentives which are guiding the agents' behavior when they act independently and in complete isolation will prevent the attainment of the more favorable outcome. Thus for players A and B, a dilemma between individual and collective rationalities arises which constitutes the distinctive feature of the PD game.

In game theory the incentive structure of the PD game and the determination of the equilibrium solution are usually described by the normal form representation as depicted in Figure 1. Here the numbers 1, 2, 3, and 4 indicate the ranking of each player's personal utilities (or "payoffs") depending on the four possible strategy pairs chosen by A and B: Player A's rank number appears in the upper and B's rank number in the lower part of each cell of the matrix. For example, number 4 in the lower left cell indicates that A reaches her most favorable position if she confesses while B does not. The stars behind the numbers indicate the optimal (Nash) reactions of each player which are obtained for player A by comparing her rank numbers in each row and, analogously, for player B by comparing her rank numbers in each column. The unique Nash equilibrium (confess, confess) of the PD game is situated in the upper left cell of the normal form where the stars of A and B coincide, i.e., where the optimal reactions of both players are consistent. A comparison between the upper left and the lower right cell (don't confess, don't confess) shows the inferiority of the noncooperative outcome relative to the hypothetical cooperative solution (Fig. 1).

Public Good Provision

The incentive structure underlying the PD game characterizes many situations of mutual cooperation between two or more agents. A very prominent example for such a cooperation problem is the voluntary provision of a public good which – particularly due to the perception of

Prisoner's Dilemma,
Fig. 1 Normal form payoff
matrix for the PD

B \ A	Confess	Don't confess
Confess	2*, 2*	1, 4*
Don't confess	4*, 1	3, 3

climate protection as a global public good – has received a lot of attention over the past few years. How a PD situation arises in the case of public good provision is even easier to explain than with Tucker's standard story about the two prisoners.

For the public good scenario, we assume that the players A and B are two countries that share the same environmental medium (water or air) and thus suffer from the same environmental damage. Each country has two options, either to take an abatement measure to curb its pollution which entails costs (c) for this country or not to abate and to carry on as usual. If none of the countries abate, no environmental damage is avoided and the environmental benefit for each country is $B(0) = 0$. If instead one single country abates, both countries will enjoy the environmental benefit $B(1) > 0$, as there are spillovers of pollution between the two countries. In other words, there is neither rivalry in nor excludability from the benefits of an abatement measure, i.e., environmental quality has the well-known properties of a public good. If not only one but both countries make an abatement effort, then each country gets an environmental benefit equal to $B(2) > B(1)$.

Concerning the relation between environmental benefits and abatement costs, it is now supposed that:

- $B(2) - c > 0$ or equivalently $B(2) > c$ which means that collective abatement efforts are beneficial for both countries.
- $B(2) - B(1) < c$ and $B(1) < c$ which says that making an own abatement effort is never worthwhile for a country irrespective of whether the other country does abate or not.

Given these conditions we obtain the same payoff structure as depicted in Figure 1 by identifying the strategy “abatement” (or “cooperation”) with “not confess” and “nonabatement” (or “noncooperation”) with “confess” in the prisoners’ story. Voluntary public good contributions made by payoff-maximizing countries non-cooperatively lead to an undersupply of the public good, i.e., to insufficient abatement activity. At the same time, there are lower net benefits for both countries compared to the cooperative outcome with collective action on public good provision. The best solution for each country is to be a free rider on the abatement activities of the other country.

In the two-country case, it is well plausible that game types which are different from PD may arise (see Osborne 2009). So if $B(1) > c$ is assumed while $B(2) - B(1) < c$ still holds, a chicken game with two asymmetric Nash equilibria results which are characterized by unilateral abatement measures of just one country. In this case unilateral abatement pays for each country (e.g., to avoid an environmental catastrophe) but not additional abatement when abatement has already been done by the other country.

Notwithstanding that, the two-agent PD serves as the prototype for a more general public goods game with many agents, where each agent affects the total public good supply not much through his own costly contributions but benefits considerably from the contributions of the many other agents. This extension to many agents further emphasizes the empirical relevance of the PD game.

Ways Out of the Dilemma

Given the unsatisfactory outcome of a non-cooperatively played PD game for its participants, naturally the question arises how to implement the cooperative solution and thus to overcome the cooperation dilemma. In order to achieve such a Pareto improvement over the noncooperative Nash equilibrium, several approaches appear to be viable.

Agents can take up negotiations and enter into an agreement in which they commit to performing the cooperative action, i.e., remaining silent or abating as in the two examples above. The difficulty of this approach is, however, that the cooperation problem may only be shifted from the level of participation to the level of internal stability of a cooperative arrangement. This is due to the fact that in a PD each agent will not want to keep her promise and implement the cooperative action after the agreement has been concluded. Defection incentives may be avoided and stability may be ensured by introducing sanctioning mechanisms. At the national level the government punishes tax evaders who do not pay their share in the cost of public goods. In line with that, PD-like scenarios already have played a major role in the traditional contract theories of the state as developed by the philosophers Th. Hobbes and J. Locke centuries ago.

However, if no central authority with sanctioning power exists (as it is typically the case for global public goods), other forms of punishment may help to solve the dilemma and to bring about mutual cooperation. If the PD is not a one-shot game but rather iterated over many periods, it becomes possible for an agent to punish her partner's noncooperation in an earlier period by refusing to cooperate in subsequent periods. The largest part of the many punishment strategies that have been conceived by game theorists are variations of Rapoport and Chammah's (1965) simple tit-for-tat TFT strategy where each player directly reciprocates by repeating the other player's preceding action. Refinements of TFT mainly differ with respect to the other player's history of actions which

trigger punishment, the length of the punishment period, and the integration of random elements in the punishment strategy. Beginning with Axelrod (1984), the success of these strategies has been tested by the use of computer tournaments. In the meantime, new strategies based on recognition and learning ("Pavlov") or gradual punishment mechanisms have proved to be even more successful in maximizing individual payoffs (Kendall et al. 2007). Note, however, that given strictly rational agents, punishment strategies only work as desired if the PD game is (at least potentially) repeated over infinitely many periods and future payoffs are not too heavily discounted.

In real-life situations punishment may also occur outside the PD by some kind of "issue linkage" which, e.g., could mean that cooperation on the provision of international public goods is fostered by the threat of trade sanctions. Moreover, if formal governmental institutions are absent, people may organize themselves and establish rules and mechanisms for an improved public good provision. In the context of local and regional commons (as fisheries or grazing lands) as specific types of public goods, the Nobel laureate E. Ostrom (1990) has demonstrated the efficiency of such self-organized governance systems as well as their potential limitations in a lot of field studies.

The basic assumptions underlying most theoretical treatments of PD are complete individual rationality and material self-interest as the players' sole motivation. These requirements are clearly not satisfied for real people in many situations (see Fehr and Schmidt 2006 for a review). Thus it does not come as a surprise that a lot of experimental studies have shown that noncooperation is not the standard outcome: In a one-shot public goods game subjects usually contribute between 40% and 60% of their endowment (Ostrom 2000), and cooperation rates in one-shot as well as in repeated PD games turn out to be significantly higher than zero ranging between 5% and 96.9% with an average of about 45% (Sally 1995; Jones 2008). The experimental setting, however, has a large impact on cooperation rates: Framing a PD as a "Stock Market Game",

for example, reduces cooperation rates while cooperation is encouraged by calling it a “Community Game” (Ellingsen et al. 2012). Moreover, individual behavior in PD games seems to be influenced by gender (Croson and Gneezy 2009) and the cultural and ethnical background of the players (Cox et al. 1991).

Recently, Khadjavi and Lange (2013) have provided evidence on behavior in a PD game played by a subject group of female inmates who after all did cooperate in 55% of all cases in the one-shot PD scenario. Ultimately the PD has thus returned to the place where it virtually started: The prison.

Definition

Prison (or incarceration) is one of the most important forms of sanction in many modern criminal system. Incarceration may impact the overall level of crime and affect criminal behavior through several channels: incapacitation, deterrence (general deterrence and specific deterrence), rehabilitation. Understanding whether individuals respond to any of the effects outlined above is a crucial aspect for the design of effective crime reduction policies.

Introduction

The most important form of criminal sanction in many modern criminal justice systems is incarceration. The utilitarian theory of punishment developed by Cesare Beccaria (1764) and Jeremy Bentham (1789) defines the extent to which incarceration or imprisonment may be considered beneficial for society as a whole. The utilitarian rationale justifies any form of punishment, under the condition that the associated benefits are higher than the implied costs. In particular, if punishment deters or incapacitates criminals, or facilitates their rehabilitation – thus bringing benefits to most individuals of a society – then punishment is socially “good,” and therefore justifiable.

From a theoretical perspective, prisons have at least five social functions. First, incarceration mechanically incapacitates criminally active individuals from committing other crimes during the length of conviction. This is the **incapacitation effect**. Second, other things equal the threat of imprisonment could deter potential criminals from offending. Indeed, in the economic model of crime, proposed by Becker (1968), potential offenders consider the expected costs of committing a crime, which are related to the probability of being captured and condemned, and to the severity of the punishment. This is the **general deterrence effect**. In turn, the **specific deterrence effect** appears when formerly convicted individuals behave in such way to avoid returning to prison. A fourth social function of prisons arises insofar as these types of facilities could potentially help rehabilitating criminals, thus favoring their social reintegration and preventing them from recommitting crimes. **This is the rehabilitation effect**. On the other hand, however, serving time in a prison may increase the criminal propensity of inmates, for instance, by enhancing their criminal network. This is the **criminogenic effect**.

Understanding whether individuals respond to any of the effects outlined above is a crucial aspect for the design of effective crime reduction policies. Over the last decade or so, the economics literature has made significant progress in studying the empirical relevance of each of the mechanisms through which prisons can help reducing crime. With a few exceptions, most of this literature has focused on the US case, thus limiting somehow the external validity of its findings.

Incapacitation

The incapacitation effect of imprisonment is extremely challenging to estimate. The earlier criminology literature based its estimates on inmate interviews. Prisoners are asked about their criminal activity prior to their last arrest, and researchers use their responses to extrapolate the counterfactual criminal behavior in the absence of imprisonment (Marvell and Moody 1994, review this literature). The resulting

estimates, that show a large variance and thus provide little useful information, have been criticized (see Miles and Ludwig 2007) for their reliance on self-reported offenses and their sensitivity to outliers (prisoners who report an unrealistically large criminal record).

A more credible approach is the one followed by Owens (2009), who exploits a natural experiment that took place in the state of Maryland in 2001. Following a law change, judges stopped considering juvenile criminal records when sentencing adult offenders, so actual sentences went down. The author then examines the crimes committed by released offenders during the time they would have otherwise been incarcerated had the law not changed. The estimated incapacitation effects are much smaller (about one fifth) than the average effect from the research based on inmates' self-reported past offences. A critique of this strategy is, however, that it hardly distinguished between incapacitation and rehabilitation or specific deterrence.

Natural experiments of this sort are, however, less than common. A different empirical approach correlates aggregate crime and imprisonment data, usually exploiting state-level variation for the USA (see Marvell and Moody 1994). This approach has, however, two main limitations. On the one hand, estimates aggregate the incapacitation and the general deterrence effects. On the other, it is challenging to find causal effects at high levels of aggregation. Again, natural experiments can offer solutions. Levitt (1996), for instance, takes advantage of the fact that state-level prison overcrowding lawsuits exogenously reduce incarceration rates. Using an instrumental variables strategy, the author finds that a 1% increase in prison time reduces state-level violent crimes by 0.4%. While this approach solves the latter critique, it cannot disentangle the imprisonment and the general deterrence effects. Other instrumental variables estimates of the joint incapacitation/deterrence effects are Johnson and Raphael (2012) for the case of USA and Barbarino and Mastrobuoni (2014) for the case of Italy.

An interesting theoretical insight of the incapacitation effect is that, as the incarceration rate increases, the average incapacitation decreases.

This is because everything else equal higher incarceration rates imply that the marginal criminal is less dangerous. Liedka et al. (2006) for the case of the USA, Vollaard (2013) for the Dutch case, and Buonanno and Raphael (2013) for the case of Italy find evidence in favor of this hypothesis.

General Deterrence

General deterrence is a function of both prison length and prison conditions (Drago and Galbiati 2012). Regarding sentence length, the available evidence suggests that the severity of punishment does deter potential criminals from engaging in illegal behavior, as predicted by the standard economic model of crime. However, as mentioned above, the standard empirical approach – that compares incarceration rates to aggregate (state-level) crime – tends to confound the effect of incapacitation.

Again, natural experiments can come in handy. Kessler and Levitt (1999), for instance, exploit the exogenous variation in prison length provided by the so-called three strikes laws in the USA. The authors use California's Proposition 8 to show that, consistent with an aggregate deterrence effect, sentence enhancements of persistent offenders cause a 4% aggregate crime reduction immediately after the passage of the law. Likewise, exploiting the exogenous variation that the 2006 Italian Collective Clemency Bill created on the expected future punishment of released offenders if recommitting a crime, Drago et al. (2009) find that larger expected punishments dissuade recidivism.

Prison conditions also factor in the expected punishment and thus have a deterrent role. Using inmates' death rates as a proxy of (bad) conditions, Katz et al. (2003) corroborate that worse facilities are associated with less crime in the USA. The policy implication of this evidence is, however, not clear. On the one hand, prison conditions are more readily manipulatable than sentences length. On the other, it is hard to argue that facilities should be made harsher for crime reduction. Moreover, the size effects obtained by Katz et al. (2003) are rather small, so the cost-

benefit balance of manipulating prison conditions is unclear. It is perhaps more promising to study the specific deterrent effect of prisons for individual who have spent jail time.

Specific Deterrence and Rehabilitation

Prisons vary substantially in terms of the quality of facilities, the services and activities offered, and the average physical space on inmates. All of these aspects potentially affect a released individual's propensity to recidivate. However, the myriad of factors that condition inmates' future behavior, and the difficulty to measure them in a systematic and comparable fashion, make it difficult to empirically investigate specific deterrence and rehabilitation mechanisms of (future) crime prevention. The available evidence is, therefore, scarce and it has limited external validity. Moreover, in the absence of individual-level data, it is hard to empirically separate the specific deterrence effect of prisons from the general deterrence effect.

Recent evidence from Italy (Drago et al. 2011) and Colombia (Tobón 2017) suggest that worse prison conditions (respectively higher mortality and higher overcrowding) increase the likelihood that former prisoners reengage in criminal behavior. In turn, evidence from the USA (Kuziemko 2007) and France (Maurin and Ouss 2009) suggests that experiencing longer sentences reduce recidivism.

Criminogenic Effect

While the evidence above points toward a positive (crime-reducing) social function of prisons, prisons can also breed crime. Indeed, inmates not only interact with a prison's facilities and rehabilitation opportunities but also – and primarily – with other inmates. From their peers, inmates can access information (about criminal markets and illegal lucrative opportunities), be exposed to a specific set of values and social norms, and get acquainted with people with similar preferences and abilities while finding

potential complementarities that reduce the costs of committing crimes.

Understanding the scope of prison-specific peer effects is crucial for the design of policies aiming at improving the effectiveness of the prison system. For instance, there is evidence that prison networks persist after inmates are released. Specifically, using data from the 2006 Italian Collective Clemency Bill, Drago and Galbiati (2012) find that sharing a prison facility with inmates of one's same nationality predicts a correlated former prisoners' post release criminal behavior.

Also, peer effects are stronger for younger individuals, the brain of whom is more malleable, and thus more vulnerable to stimuli from the environment (Giedd 2004). Consistent with this observation, Bayer et al. (2009) estimate large peer effects on subsequent criminal behavior for juvenile offenders of the same correctional facility in Florida.

To conclude, there are several mechanisms through which prisons can influence society's crime rates. While challenging, empirically distinguishing the contribution of each one of them to reduce (or exacerbate) crime, is of foremost importance for public policy.

Data privacy; Information privacy

Definition

There is no universal agreement on what is privacy. Within law and economics, privacy has been modeled as concealment of personal information (Posner 1978, 1981) and as the standard deviation in the probability distribution forming people's perception over our personal information, with privacy loss being a tighter posterior in that distribution (Cofone and Robertson 2018a).

Introduction

The law and economics literature on information privacy revolves around two dialogues, one normative and one empirical. To a large extent, these dialogues have remained separate. The normative dialogue asks whether privacy is worth protecting, to what extent, and how. The empirical dialogue focuses on better understanding consumer behavior through experimental methods.

Normative Privacy

The puzzling aspect of the normative debate is that while much of the normative economic literature argues categorically against privacy protection, most of the legal literature does not address these arguments and moves directly to second order questions of degree and manner: to what extent privacy should be protected and how.

For Posner (1978, 1981), privacy creates an information asymmetry that disadvantages the buyers in the market (e.g., employers in job interviews), thereby re-distributing wealth and creating inefficiencies. There are individuals with good and bad traits, and the individuals with bad traits want to hide them (privacy), while the individuals with good traits want to show them. Privacy allows individual to hide their traits to deceive others and thus reduces the information with which the market allocates resources. Stigler (1980) adds that people who want information about someone protected by privacy will use other less precise (and usually less intrusive and costlier) substitutes as a proxy for the data they

want to acquire, so privacy law is at best ineffective. This is similar to an application of the Coase theorem: as long as transaction costs remain low, whether there is a privacy rule (which allocates the right over information to the person to whom that information refers) or there is no privacy rule (which allocates information to whoever finds it) is irrelevant for the information's final allocation. For that reason, under a no-transaction-cost condition, introducing disturbances in the market such as information asymmetries, which would be welfare decreasing, is unjustified. Later research takes a similar approach for information in the financial market, arguing that allowing firms to collect and sell consumer data leads to increased overall welfare (Kahn et al. 2005; Kim and Wagman 2015).

Some resistance to the idea that privacy is necessarily inefficient is later introduced. Introducing a model where individuals suffer reputational harm from the loss of privacy, Daughety and Reinganum (2010) show that privacy protection allows people to engage in an optimal level of desired activities. Cofone (2017) shows that the conclusion that privacy is always inefficient holds only in a static world, but not in a dynamic world where information production is costly. Gradwohl and Smorodinsky (2017) show how privacy concerns affect people's choice of actions in strategic settings.

In the legal literature, Solove (2006) introduces a taxonomy of six different conceptions of privacy: (i) as the right to be left alone, (ii) as autonomy, (iii) as secrecy or concealment of discreditable information, (iv) as control over one's personal information, (v) as personhood and preservation of one's dignity, and (vi) as intimacy. The two conceptions that use law and economics arguments to approach privacy normatively have been secrecy (the approach taken by Posner and Stigler) and control. The latter mostly involves a discussion on whether a property right protection over personal data is warranted. While some suggest a protection regime similar to that of property (Murphy 1995; Schwartz 1999, 2004), others are skeptical of the idea. They argue that the reasons to protect property or intellectual property and the reasons to protect privacy are different (Litman

2000; Samuelson 2000) and that the debate around privacy should focus not on property but on autonomy (Cohen 2000).

More recent literature addresses privacy harms. Calo (2011) distinguishes two different dimensions of privacy harms: intrinsic privacy harms, which relate to privacy in itself, and extrinsic harms, which relate to material damage that is independent of privacy, such as financial damage resulting from identity theft or annoyances from spam – where the latter have been the focus of the prior privacy literature. Calo (2014) explores extrinsic privacy harms further and shows how people's personal data can be used to influence their decisions. Along the same lines, Conitzer et al. (2012) show that, counterintuitively, both a low and a very high level of privacy lead to price discrimination and produce extrinsic privacy harms by allowing sellers to capture all surplus, while an intermediate level of privacy is best for consumers. Regarding intrinsic privacy harms, Cofone (2016) introduces a method to quantify intrinsic privacy harms in the context of medicine, which presents a unique context in which privacy preferences can be measured with a dollar value. Cofone and Robertson (2018a) introduce a model of privacy harms that takes into account privacy preferences and therefore captures intrinsic privacy harms, separating it from reputational harms, and apply it to tort law and criminal procedure. Cofone and Robertson (2018b) apply a modification of such model to the context of consumer privacy and show that the nonbelief in the law of large numbers can justify consumer privacy regulations.

Empirical Privacy

The empirical law and economics dialogue takes place mainly in the economics of privacy literature, and it has been called “the new economics of privacy” (Acquisti et al. 2015). It consists of insights on how consumers behave regarding their personal information, and contains sometimes unexplored policy consequences. One of its central findings is that privacy decisions are affected by cognitive and behavioral biases, such as

immediate gratification or status quo bias (John et al. 2011). Acquisti et al. (2013), for example, show that consumers exhibit a much higher discrepancy than normal between their willingness to pay and their willingness to accept than in other choices: the value that consumers place in protecting their personal information differs to up to five times depending on the framing of the question. It has also been demonstrated that privacy concerns vary both with context and with personal traits (Acquisti et al. 2015).

Another central finding, and perhaps the central puzzle of this second dialogue, is the “privacy paradox.” The paradox describes the phenomenon in which people declare a high value for their private information in surveys but, in incentivized experiments, they disclose such information for low compensation. Studies on how much people value their privacy show an inconsistency between their declared concern for privacy and their actual behavior online (e.g., Norberg et al. 2007; Beresford et al. 2012). Privacy concerns are a weak predictor of the amount of personal information disclosed. However, consumers are not completely unreactive to privacy. Advertisements that are targeted and obtrusive are more likely to trigger privacy concerns among users than advertisements that do not match the content of a website (obtrusive but not targeted or do not impede visibility (targeted) but not obtrusive) (Goldfarb and Tucker 2011). People's ability to deal with privacy choices changes with their complexity (John et al. 2011). Consumers are also willing to pay to purchase from merchants that protect their privacy when privacy policies are available and their content is salient (Tsai et al. 2011). And, as shown through a series of surveys asking about personal financial information, privacy concerns have increased over time (Goldfarb and Tucker 2012).

Another major finding is the extent to which consumers are unaware of what policies they agree to and what happens with their data – uncertainty that is usually referred to as “consumer unawareness.” Milne and Culnan (2004) show that people rarely understand privacy policies and license agreements. McDonald and Cranor (2008) show that a disproportionate amount of

time and energy would be needed to read all privacy policies one is involved with. Hoofnagle et al. (2012) show that the advertising industry finds new ways of tracking that consumers are often unaware of. Hoofnagle and Urban (2014) show that consumers are unaware of the extent in which they are subject to behavioral targeting and believe that there are implied duties of confidentiality also when these do not exist. There is discussion on whether privacy notices are effective at counteracting this. Some show empirical evidence of their ineffectiveness to increase consumer awareness (Martin 2016). Others find that simplifying such disclosures along standard best-practices also has no effect (Ben-Shahar and Chilton 2016) and that consumers are unreactive of different types of language in privacy policies (Strahilevitz and Kugler 2016).

Abstract

Privacy regulation is a set of rules and enforcement tools designed to control the collection and use of personal information. Not only these rules aim at protecting privacy, but also reducing the scope of misuses of information including identity theft, higher prices, spam, and effort spent by individuals to protect their data. The spectrum of privacy instruments varies from purely (self-regulating) market-based solutions to regulatory-orientated rules and from ex ante to ex post tools. The protection of personal data involves costs for firms, such as the restriction of available information and detrimental effects on innovation. From the consumer point of view, costs are related to consent and information issues, such as reading or writing privacy charts, complying with privacy standards and adopting privacy-enhancing technologies. Since there are privacy trade-offs arising from the interaction between this regulation and other economic and social issues, the economic impacts of privacy regulation depend to the adequacy of the privacy protection arrangement to the context.

Definition

Privacy regulation is a set of rules and enforcement tools designed to control the collection and use of personal information.

Privacy Regulation

Privacy regulation is a set of rules and enforcement tools designed to control the collection and use of personal information. Not only these rules aim at protecting privacy but also reducing the scope of misuses of information including identity theft, higher prices, spam, and effort spent by individuals to protect their data. It articulates legal rules (US *Privacy Act*, French law “informatique et libertés”), the role of medias and civil society, the use of technologies (encryption, anonymous web browsing), and the actual behavior of organizations and individuals, that are more or less privacy sensitive. The weighting of each of those factors varies among countries: for instance, the role of medias in the USA proves to be stronger than in European countries. As for the public intervention to protect privacy, the USA and the EU have adopted two different approaches. While the USA is limited to ad hoc regulation, the EU puts the spotlight on general regulation based on principles.

Various instruments permit to regulate privacy. There is a spectrum of solutions between purely market-based ones (reductionist approach supporting self-regulation of firms) to regulatory-orientated rules (strict application of notice and consent mechanisms). Many authors focus on the cost-benefits analysis and comparisons of these solutions (Swire 1997; Bennett and Raab 2006; Koops et al. 2006). Privacy instruments can also range from ex ante tools that apply before the damages (e.g. legal prohibition to collect data on minors, privacy by design rules, the fair information practices) to ex post solutions (e.g. a liability rule, the right to be forgotten).

Literature on privacy regulation has emerged since the 1970s with the enactment of the US Privacy Act. In particular, Judge Richard Posner (1981) considers it as a source of market

inefficiency. By hindering the capacity of firms to gather personal data, privacy is supposed to reduce the information available in the markets about consumers, workers, borrowers, and so on. However, the advent of the Internet and digital platforms renew these issues. Moral hazard issues derive from the costs to observe the uses that firms make from the data they gather over individuals. Their well-being is undermined from such a position of imperfect or asymmetric information regarding who collect their data, when, for what purposes, and even with what consequences. At the same time, regulating firms can impose them important legal costs that could have detrimental effects on innovation and business.

The design of an efficient regulation raises many difficulties. One is to assess the optimal rules of the regulation because this requires a large amount of information that regulators rarely know. For instance, what are exactly the actual harms due to privacy infringement and how to evaluate them or who are the “polluters” in a digital environment? It proves very uneasy to know who gather what kind of information and to do what.

Another problem is that privacy protection can be a source of failures (Rubin and Lenard 2001) either because of their implementation costs (e.g., detection of unlawful behavior) or because of their consequences (e.g., restrictions on digital innovations). The costs of implementing privacy regulation might be higher than those rising from privacy abuse. For instance, internet users benefit from free online services, social networking service, and targeted advertising thanks to the exploitation of their online data. Quite often, privacy regulations require a combination of various instruments (institutional design), and thereby they can interact with other regulations and laws. Some authors support self-regulation by considering firms (advertisers, website, and platform operators) as sensitive to the consumer response to their strategies whenever these ones prove intrusive (invasive or too much targeted ads, spam, and unacceptable price discrimination) and irritate consumers (Anderson and Simester 2010). Hence, firms can engage themselves

in pro-privacy competition, for instance, by choosing to actually comply with their privacy commitment (Jamal et al. 2003). However, the efficiency of self-regulation supposes a certain ability of individuals to be informed and the capacity of firms to provide protection of privacy without excessive costs (Swire 1997). Here, the advantage of more strict regulatory solution is to permit individuals to save on costs associated with the need for complex information inherent with various privacy policies and interaction with firms that exploit their data (Milberg et al. 2000).

From an economic point of view, the efficiency of any privacy regulation is to minimize the social cost associated with the exploitation personal data while maximizing its social welfare. Therefore, there are at least three criteria to evaluate the efficiency of a privacy instrument (Rallet and Rochelandet 2011). First, a privacy instrument can be considered as efficient whenever it minimizes the transaction costs associated with its setup and enforcement. Privacy involves costs for the consumers, including the costs of consent when they want to use an online service. More generally, private agents can incur information costs, i.e., when reading or writing privacy charts, complying with privacy standards, adopting privacy-enhancing technologies, and so on. The same prevails for public institutions when they set and enforce privacy rules with the surveillance and detection of unlawful behavior. All these costs are unequally allocated among institutions, organizations, and individuals, and hence the resulting allocation could affect the social benefits of such or such privacy instrument. For instance, a property rule in favor of individuals can be inefficient because these ones are not always in the best position to assess the value of their data, leading to overestimation from their part and then less innovation and socially useful exploitation of their data. Similarly, charging too stringent privacy norms to firms can be costly for them to comply with, leading to underinvestment in innovation and quality of service.

Secondly, in order for privacy regulation to be efficient, rules assigned to every regulated agent must be followed by them. However, incentives as

well as financial or cognitive ability might be insufficient. For instance, psychological biases can lead to overexposure of individuals over digital platforms, even though they have strong preferences for privacy (Acquisti et al. 2015). In addition, firms can benefit from asymmetric information when it appears to be costly to observe their behavior, resulting in an exploitation of resources in the market for personal data (Schwartz 2004). Moreover, privacy rules can lead to firms to adopt inefficient decisions. For instance, they can decide to adopt business models (Cecere and Rochelandet 2013) or to locate their business according to the actual level of privacy (Rochelandet and Tai 2016).

Thirdly, There are privacy trade-offs arising from the interaction between this regulation and other social issues such as innovation, health, antitrust, and public order. How to best protect privacy without harming the positive effects of information sharing and exploitation? To some extent, privacy rules can complement or, conversely, be opposed to other policies through its effects on the functioning of markets. In a market perspective, ex post regulation is held to be more in favor of innovation by letting the market and innovation process work, even if it means subsequent privacy harms. However, such damages might be irremediable because they result from the use of information goods that are nonrival and then hard to seal off. However, too vigorous privacy regulation can be inconsistent with other social issues such as health, public order, freedom of speech, and innovation. For instance, the fact that European Union Data Protection Directive is more restrictive than the US Privacy Act could lead to a reduction in welfare (for instance, in health services, Miller and Tucker 2011) or a reduction in the general level of privacy protection (Rochelandet and Tai 2016 show that stringent privacy laws may lead firms to locate in less stringent countries, what weakens the actual privacy protection).

Possible approaches to privacy protection range from market-based solution to formal regulation. Thus, different frameworks are in-between self-regulation and strict regulatory protection. The economic impacts of privacy regulation

depend to the adequacy of the privacy protection arrangement to the economy context.

Abstract

This entry focuses on the legitimacy of private property and analyzes the process of first appropriation. In particular, we examine and comment the different views on the origin of private property rights that have emerged through the history of economic and legal thinking, from Democritus to de Jasay. These views have been grouped in two broad categories: consequentialism and fundamental principles. Although consequentialism is now dominant among economists and inchoate in the legal profession, we observe that it is in fact an alibi for discretionary policymaking by the authority. By definition, fundamentalist approaches generate rules that limit discretion. However, we show that some fundamentalist views rest on questionable *a priori* statements. De Jasay's argument based on the presumption of liberty is perhaps the only perspective that escapes this criticism.

Introduction

Property rights play a crucial role in economics: They define the very essence of this discipline, which studies how individuals exchange in order to enhance their welfare, subject to scarcity constraints. If there were no property rights, grabbing and looting would replace exchange, and the time horizon of any economic activity would depend on how effectively and at which cost each individual can protect the goods under his/her control.

One can identify three categories of property rights regimes: common property, centralized property, and private property (see also Waldron

2016). Common property defines a context in which the notion of property is abolished or severely restricted. It is in fact equivalent to the absence of property rights: Every individual in the relevant community/group is free to claim and appropriate everything he/she finds. The underlying idea is that individuals produce for their own immediate consumption or for the community at large (altruistic behavior with an expectation that the others will behave likewise) and that each individual has a right to take and consume whatever he likes. Theft is thus *de facto* legalized, unless it involves physical violence. Actually, one could even argue that theft no longer exists, because there are no legal owners and no member of the community has the right to prevent others from taking.

Not surprisingly, this social arrangement is of limited practical interest. It would quickly lead to the demise of the community (hardly anybody would produce goods and services, except for situations in which they can be manufactured secretly and consumed immediately) or to slavery (the most effective looters would force the rest of the community to produce and surrender their output). Of course, in the latter case, the slave masters would be the actual owners.

By contrast, centralized property corresponds to a system in which property rights are clearly assigned and belong to a central authority. This authority can be an individual, such as a dictator or an absolute sovereign. For example, since the end of the XVI century, absolute monarchies were based on the idea that God gave all the existing resources to one individual, who would then manage them in the interest of the community and in accord with God's design. The central authority can also be a set of individuals chosen through a shared procedure (elections). This set of individuals often operates by majority voting (e.g., parliaments) or assigns to other parties the power to decide on its behalf (e.g., an agency). Centrally planned economies and modern social democracies follow these patterns. In these circumstances, the expression "private property" is not absent from the debate, but it is in fact misleading. For example, in modern democracies, the central authority enjoys full power to encroach upon

somebody's property. This means that in a social democracy, the central authority allows individuals to make use of the goods in their possession within the limits defined by the central authority itself. As a result, the ultimate owner is actually the central authority, rather than the individual. In these cases, therefore, individuals engage in economic activities with other individuals, subject to their expectations about encroachment by the authority on their preferences and (temporary) property. When individuals interact with the government widely understood (policymakers, bureaucrats, agencies), they know that their counterparts are the ultimate judges of their own behavior and therefore enjoy discretionary power to which little opposition is possible. As mentioned above, property is merely temporary and far from absolute.

The recognition and enforcement of private property rights are the founding pillars of a free-market economy. Private property means that individuals have absolute, exclusive, and permanent rights on what they legally own: they can do whatever they like with their property, nobody can interfere with their decisions, and there is nobody to whom these rights must be returned after a given time period. Thus, under this regime, each individual engages in unfettered voluntary exchange, subject to his/her compliance with the freedom-from-coercion principle (no violence and no cheating are allowed) and insofar as he/she respects the private property of the other individuals. Put differently, the legitimacy of private property and the freedom-from-coercion principle specify the moral foundations of a free-market economy. By contrast, the illegitimacy of private property and the limits to private property define the features of the centralized economies, regardless of the political format – dictatorship or social democracy.

The debate on the origin and legitimacy of private property is thus of crucial importance, since it defines the very features of an economic system (institutions), the role of government, and the content of economic policymaking (see also Alchian 1965). Briefly put, the debate on the legitimacy of private property focuses on two areas. One regards property rights on natural

resources, while the other regards property rights on manmade goods, services, and intangibles. Research on the origins of private property analyzes and explains the process through which an individual can legitimately appropriate a resource never previously appropriated by somebody else. Moreover, the literature examines whether the goods, services, and ideas produced by the individual become private property of the producer; or whether they actually belong to somebody else, e.g., the community of which the producer is a member; or whether they are part of the common pool and thus belong to nobody.

The following sections provide a critical analysis of these two agendas by considering the different views developed through the history of economic and legal thinking. In particular, the next section is devoted to the consequentialist, natural right, and religious beliefs before John Locke. Section “[Aquinas and Locke on the Process of Appropriation](#)” explores the notion of property as the result of rightful appropriation. Section “[A Different Natural Right Approach to Private Property: Natural Dominion](#)” focuses on natural dominion, while section “[Recent Free-Market Agendas: From Demsetz to De Jasay](#)” discusses the more recent approaches. The final sections conclude and offer a brief outline of the debate about intellectual property rights.

Private Property Before John Locke: Democritus, Aristotle, and the Etruscan Legacy

The first attempt to justify individual appropriation – as opposed to common property – harks back to Democritus (460–370 BC). In his view, private property is justified because it leads to superior economic results (efficiency). In a sentence, individuals make better use of the resources when they own them (Diels 1903: 55 B, frag. 279). In today's wording, one would say that when private property rights are well defined and enforced, the positive and negative externalities generated by the use of a resource are minimized, and efficiency is enhanced.

According to this approach, therefore, private property is just because it leads to desirable outcomes, efficiency being the criterion that defines desirability. Surely, this view is squarely in the consequentialist camp: morality defines justice, and, in turn, the desirability of the outcomes associated with one action or one institutional arrangement defines morality.

However, considering desirability (indirectly) equivalent to justice presents one major weakness. It fails to specify who should define desirability. This is not a trivial aspect, since it is apparent that different individuals are likely to have different preferences and thus attach different meanings to the notion of “desirable.” For example, one could follow Plato and argue that since each individual should pursue virtue, and since private property encourages greed and social tensions to the detriment of virtue and peaceful coexistence, private property should be outlawed. Likewise, the very notion of efficiency is ambiguous. Efficient is whatever enhances value. Yet, value is subjective, and, therefore, the notion of efficiency can vary across individuals and groups of individuals, depending on preferences, religion, traditions, and culture. Certainly, technical efficiency is by no means enough to measure social happiness, whatever this means.

The upshot is that if one follows this consequentialist viewpoint, the presence, the boundary, and the stability of private property rights are conditional on a notion of desirability that is necessarily arbitrary and subject to change over time. Put differently, by resorting to the notion of desirability in order to legitimize private property, one actually avoids analyzing the foundations of private property and moves instead to comparing different concepts of social desirability. Yet, this comparison is hardly conducive to a useful answer. In order to avoid arbitrary rule, therefore, the notion of social desirability requires that the members of the community unanimously agree on a hypothetical desirability function (social preferences). Moreover, this notion also requires that the community members unanimously agree on the institutional tools that allow a society to obtain the desired set of goals (policymaking): when raising revenues to finance desirable public expenditure,

a tariff on car imports is different than a tax on inheritance. Failure to meet these two social choice constraints – shared goals and shared instruments – ensures that we can say little or nothing about the consequentialist justification of property in a society.

Aristotle (384–322 BC) enriched Democritus’ arguments in favor of private property by mentioning the role of human nature. According to his line of reasoning, since history and factual observation show that individuals like to own resources and goods, one must necessarily conclude that the principle of ownership is indeed part of human nature (see *Politica*: I,8 and II,5). Hence, the institution of private property is part of natural law, and denying or constraining private property would amount to negating the essence of each human being and of the natural order. The Romans also referred to natural law: the use of reason, the observation of reality, and consistency with tradition are the instruments through which cultivated men discover the natural law – “*si in unum sententiae concurrunt, id, quod ita sentiunt, legis vicem optinet*” (Gaii Inst., I § 7). And private property is part of the natural law (Gaii Inst., II §§ 66, 69, 73, 79).

However, and despite its simplicity and consistency, the Aristotelian version is also vulnerable to doubts. By claiming that the foundation of private property lies in natural law, one makes a statement that raises additional questions, rather than answers the original query. Put differently, by claiming that private property is founded on natural law, one wonders whether private property is indeed a component of natural law. One can also ask why natural law is superior to positive law (manmade legislation) and – last but not least – who has the final word on all these questions.

A third and final vision on private property was typical of the Etruscans and very popular with the Romans. As mentioned in Liggio and Chafuen (2004), religion is a family matter: each family’s ancestors are sacred and present a sacred link with the land upon which the family insists. Violating that land and – more generally – the family’s belongings was sacrilegious and usually deserved capital punishment, as the Romulus and Remus legend witnesses. Thus, there could be no religion

(and no family) without private property. Hence, private property is not a matter of economic efficiency, nor is it related to human nature. Rather, it is the necessary connection between the household and the gods. It is part of the essence of classical civilization and an element that will also play a crucial role in the defense of private property put forward by the early Fathers, together with the obligation of sharing with “the poor [...] the fruits of [the owner’s] labour” (Lactantius, *Divine Institutes*, V, 5).

Aquinas and Locke on the Process of Appropriation

St. Thomas Aquinas (1225–1274) produced two original insights, from which a theory of private property legitimized by rightful appropriation emerged. Aquinas agreed with the dominant classical worldview on the desirability/efficiency of private property. Yet, he made a second point, which was new and of great importance. He argued that unused resources do belong to humankind. However, when an individual combines them with his own labor, his claim to the resources trumps all others’ and transforms possession into private property (this is one way of reading *Summa Theologiae*, II-II, 66, 1). A few years later, this argument was forcefully repeated, clarified, and expanded by John of Paris (1250–1306), a student of Aquinas’: “lay property is not granted to the community as a whole. ..., but is acquired by individual people through their own skill, labour and diligence, and individuals, as individuals, have right and power over it and valid lordship; each person may order his own and dispose, administer, hold or alienate it as he wishes, so long as he causes no injury to anyone else since he is lord” (quoted in O’Donovan and O’Donovan 1999: 403; see also Rothbard 1995: 57; and Kilcullen and Robinson 2017).

In modern times, John Locke’s *Second Treatise* (1689, chapter V) popularized and expanded the line of theorizing initially proposed by St. Thomas and John of Paris and later enriched by the Dominican Francisco de Vitoria

(1483–1546), the Levellers, and Earl Shaftesbury (see Lepage 1985: 63; Rothbard 1995: 315–317; see also Vaughn 1980). Locke’s line of thinking can be summarized in six points:

1. God gave natural resources to humankind, and are part of the so-called state of nature.
 2. Every individual is the owner of himself.
 3. By mixing natural resources with his own manual labour, ideas and creative efforts, the individual removes the resources from state of nature and makes them his own.
 4. Property includes the resources initially appropriated as well as their fruit.
 5. Since God would disapprove of wastage or abuse, appropriation is no longer valid when private property involves wastages, or when appropriation prevents other people from satisfying their needs.
- From a normative viewpoint, Locke argues that the preservation of property is the only function of the social contract, which is the origin of government, an institution formed by individuals who agree on finding a peaceful solution to disputes. In fact,
6. Private property pre-dates government and justifies its existence.

Clearly, the notion of the “state of nature” plays a key role in the Lockean context. This concept was actually introduced by Juan de Mariana at the end of the sixteenth century. It is a synonym for the common pool and defines a situation in which resources do not belong to anybody, not even to the community as a whole. Put differently, one could argue that Locke did not theorize private property as an institution inherent in nature or legitimate per se, but rather as a desirable manmade institution that originates from common property (in the state of nature) and ownership of one’s own self. It materializes through an act of appropriation (removal of a resource from the state of nature), is consistent with God’s will, and is subject to constraints dictated by God’s will.

All in all, Locke’s theory remains incomplete and not entirely satisfactory. As observed earlier, his key elements are the emphasis on the role of

self-ownership, which allegedly justifies ownership on what the individual removes from the state of nature (the finders-are-keepers principle already formulated by Gaius, Inst. § 66), and the fact that God is not opposed to private property. However, this is Locke's weakness; it is not evident that self-ownership justifies grabbing from the common pool. Locke's view about the legitimacy of private property is more a description of how private property emerges, rather than an explanation of legitimacy. In other words, the essence of Locke's argument boils down to claiming that God created common property and that He does not object to grabbing for a good purpose (wealth creation). In this light, one may indeed argue that Locke's line of reasoning rests on consequentialism (wealth creation), possibly mixed with an act of faith (God wants people to improve their welfare well beyond what is needed to survive and private property serves that purpose). Hence, the Lockean vision not only presents the limitations typical of all consequentialist approaches but also relies on one's vision about religion and is burdened by the famous proviso which, if taken literally, de facto prevents first appropriation in the presence of scarcity or makes first appropriation conditional on everybody else's consensus.

A Different Natural Right Approach to Private Property: Natural Dominion

Consequentialism and appropriation are surely the most popular arguments in favor of private property. As mentioned earlier, consequentialism harks back to classical Greece and maintains that private property is justified by the desirable results (efficiency) it produces. By contrast, the case for appropriation was put forward in the Middle Ages; it was further developed by Locke and implies acceptance of the dominion thesis: consistent with God's design, men are free to exploit natural resources (including animals), and private property is the outcome of appropriation by an individual or a group of individuals, as long as no other human being is harmed.

However, the Middle Ages not only claimed that private property is desirable and consistent with God's design. Not long before the end of its pontificate, Pope John XXII (1249–1334) argued that private property is just also from a deontological perspective. In his view, and in contrast with other property regimes, private property stems from "pure" natural rights. As argued in the encyclical *Quia vir reprobis* (1329), which the Pope released to condemn Franciscan pauperism, God owns whatever exists, and since man has been created in the image of God, the principle of private property is necessarily embedded in the very nature of each human being. Hence, limiting private property would amount to disputing God's design. Of course, in this case, the adjective "pure" is important, since the pure version of natural rights emphasizes that these rights are embedded in each individual since his/her birth.

This natural-dominion approach differs from the Aristotelian version, according to which natural rights are those revealed by spontaneous behavior and tradition. And it also differs from the rationalist version, which owes a great deal to Grotius (1583–1645), according to whom natural law coincides with what is needed to ensure survival, while natural rights are manmade absolute rights dictated by reason and independent of the circumstances. Within the framework suggested by Grotius, therefore, sociability is the moral benchmark with reference to which all institutions are evaluated, and private property is the operational tool to meet sociability (man's inclination to live in harmony with other human beings).

Of course, the normative consequences of the natural-dominion thesis are important. According to this approach, private property is all but sacred and can never be encroached upon; whereas according to the rationalist perspective, private property ends up being the result of human constructivism and has nothing to do with religion. This also affects the very notion of right. In the former case, a right corresponds to one's freedom to use a resource as he pleases; whereas in the latter (rationalist) case, it corresponds to one's claim to enjoy something, as dictated by the (hopefully) enlightened authority.

Recent Free-Market Agendas: From Demsetz to De Jasay

In recent times, the debate on the origins of private property has subsided, with few exceptions. Indeed, mainstream theorizing has taken an evolutionary turn. Bordering with Benthamite utilitarianism, Demsetz (1967) and Pejovich (1972) pioneered an approach that neglects the moral justifications of private property and tends to treat this institution as the spontaneous result that emerges when groups of individuals face the problem of scarcity. In this context, the term “spontaneous” underscores the fact that private property is the result of human action, but not the result of constructivist design. Rather, it originates from trial and error, so that bad solutions lead to unsatisfactory performance and tend to be discarded in favor of superior institutional answers (see also Barzel 1989: Chap. 6).

In brief, it is claimed that private property emerges when unrestrained access to scarce resources leads to inefficiencies (overexploitation) and when a community finds it appropriate to generate incentives that drive individual behavior in a desirable way. Put differently, private property is a way of granting access only to selected individuals (the legitimate owners) and of managing valuable goods by internalizing potential externalities. Two consequences follow. First, private property is a manmade institution, the features of which evolve according to the current environmental conditions (transaction costs, preferences, technology). Thus, it can be neither absolute nor perpetual. Second, this evolutionary approach raises a normative issue: Who defines the features of a private property right system? This literature draws attention to the institutional entrepreneurs, who devise and experiment alternative property arrangements, and to the judges, who carry out the necessary cost-benefit analyses following which property rights are assigned and reassigned. As a result, good arrangements survive and bad arrangements are corrected, ignored, or discarded. However, when judges, experts, and lawmakers are responsible for the assignment, the recognition, and the enforcement of property rights, the outcome is *de facto* determined by government, and spontaneity

necessarily falls victim to state coercion. Not unlike Jeremy Bentham and John Stuart Mill, therefore, one hopes that coercion pursues the common interest, whatever this means; and one neglects to notice that the interests of the majority end up trumping those of the minority.

More generally, the recent evolutionary approach mentioned above follows the Lockean tradition in that it has little to say about the origins of private property. Similar to Locke, it provides a consequentialist description of how private property emerges. However, Locke based his consequentialist approach on God’s will. By contrast, the law-and-economics tradition to which Demsetz and Pejovich belong bases its consequentialist claim on the utilitarian stamp of an enlightened government. This explains why, and in contrast with the Lockean tradition, the evolutionary approach takes for granted that government precedes private property: legislators create the law in accord with utilitarian principles, and the law defines private property.

Not surprisingly, in order to recover the essence of the debate on the origin of private property, one has to focus on those libertarian scholars who deny the legitimacy of government as a coercive authority, a role that necessarily transforms the state into the source of property. In particular, by drawing on John Locke, these unorthodox authors maintain that private property preexists government and that, therefore, government cannot encroach upon private property.

In order to develop their argument, the libertarians follow two lines of reasoning, which do without God and religion and ignore Locke’s proviso (see Bouillon 2011). The first one starts from the notion of self-ownership and generalizes this principle into an ethics of private property. A second perspective focuses on a different notion of legitimacy, which turns the burden of proving the legitimacy of private property upside down by relying on the notion of Paretian optimality.

Rothbard (1974) is probably the most prominent proponent of the first view, based on an *ex contrario* argument. Rothbard justifies appropriation by observing that we live in a world of scarcity and that a resource is scarce if at least two individuals want to exploit it. Now, individual

A does not need to ask permission to exploit/appropriate the resource if it is a first appropriation. Thus, A becomes the lawful first owner. By contrast, if A must ask permission, it means that B (or somebody else before him) had already become the owner (or the co-owner) through first appropriation. Put differently, the Rothbardian perspective transforms the debate on private property into an analysis of the legitimacy of first appropriation. If one denies the right of first appropriation, all potential first owners should behave as if all resources were in common, including their own selves and the air they breathe (see also Boaz 1997). This would be absurd, since if each individual had to ask permission to act and breathe from billions of other people, the human race would quickly perish.

Rothbard also rejects the possibility that the individuals are at least partially owned by others – e.g., policymakers – who take decisions in the interest of the rest of the community. In his view, this possibility would be immoral and contradictory. It would be immoral, because all moral rules require generality (all individuals must enjoy the same rights). It would be contradictory, because accepting asymmetric ownership would be equivalent to saying that the human race is actually made of humans and non-/subhumans. According to Rothbard, therefore, the first appropriation is a law of nature because it is necessary for survival and establishes a general principle. Hence, the natural origin of private property. This principle is moral and also applies to the first appropriation of what an individual creates with his own labor.

De Jasay (1991, 1998) is an advocate of the second approach, based on the so-called presumption of liberty, i.e., on the idea that an individual can act as he pleases, unless a challenger falsifies the presumption by raising justified objections. Justified objections stem from three situations: (1) when it is apparent that an action conflicts with (spontaneous) conventions, (2) when the actor violates obligations that he had previously and voluntarily assumed, and (3) when somebody else's liberty to act is impaired (harm). The third condition is actually reminiscent of the weaker Lockean proviso, which is how Robert Nozick (1974: 178–182) identified a situation in which

individual A's action prevents others from exploiting opportunities to enhance their well-being. Although situation (3) above remains ambiguous – one could eliminate all ambiguities by understanding the term “harm” as a synonym for physical violence at the expense of the challenger – the core thesis outlined by Nozick and De Jasay is clear: the legitimacy of first appropriation is guaranteed by the lack of opposition by individuals who could claim a previous right over the good/resource. If such opposition had substance, then the finder would not be the first finder and could not keep the good. Another individual is in fact the first finder or the legitimate owner of the goods he obtained from the true first finder.

Put differently, and absent justified opposition, the finders-are-keepers rule is consistent with the presumption of liberty and necessarily represents a Pareto improvement: it makes the finder better off and makes nobody worse off. The second comer would be in a different position, since his claim to the goods appropriated by the finder would violate the presumption of liberty and would not be a Pareto improvement. Of course, the presumption of liberty also applies to private property obtained through exchange or by means of inheritance and to self-ownership.

To summarize, by articulating a presumption of liberty, De Jasay introduces a negative notion of legitimacy: all non-illegitimate actions are legitimate, and the burden of proof lies with the challenger. Since the presumption of liberty is met when nobody has justified cause to object, and since the absence of objection is also the essence of a Pareto improvement, all actions that imply a Pareto improvement are necessarily legitimate. In regard to the legitimacy of private property, therefore, the debate boils down to assessing whether an individual's property is based on a previous act of appropriation that violated the presumption of liberty. Clearly, this would be the case with theft, nationalization, or expropriation.

Preliminary Conclusions

By and large, the arguments in favor of private property have focused on three points:

characterizing property rights in the initial status quo, justifying the legitimacy of private property through consequentialism, and explaining the legitimacy of private property by resorting to fundamental principles.

In regard to the first point, the literature analyzes various possibilities. According to one version, the initial position consists in the state of nature, where resources belong to nobody and can be appropriated by the homesteader (first-user principle), possibly with some qualifications (the Lockean clauses). A second version consists in claiming that the initial position involves common ownership of the resources and that regulating the exploitation of the resources owned by a community is a political issue. In practice, the government decides who can use what and to what extent. Hence, government is in fact the origin of private property. This means that an individual manages what the government assigns to him, subject to the conditions and during the time period established by the authority. Following a third perspective, it has been claimed that the origin of private property is the individual property of one's own self, a concept that defines the very idea of individual and in the absence of which life would be impossible. Finally, according to a fourth (and radical) possibility, it is argued that the initial position is irrelevant and that, given a presumption of liberty based on self-ownership, what matters is the extent to which the various steps that have led to the current status are objectionable. Of course, lack of objections amounts to confirming the legitimacy of homesteading and exchange.

With the partial exception of the view proposed by De Jasay, private property of manufactured goods is considered an extension of the principle of self-ownership. If an individual combines the resources he owns – land, raw materials, and labor – denying his property right over the output would involve an act of aggression and amount to a violation of the freedom-from-coercion principle. On the one hand, since each unit of output is a mix of inputs owned by the producer, each unit of output is necessarily property of the producer. On the other hand, it is manifest that the manufacturer is the first finder of the result of his activity and

that nobody can raise justified objections to the manufacturer's exercise of his liberty (acting as a producer and producing and appropriating the result).

As mentioned earlier, the second set of explanations regarding the origins and foundations of private property focuses on private property as an institutional arrangement justified by efficiency: it ensures better economic outcomes and wards off social tensions. Although this approach is dominant among economists and inchoate in the legal profession, it remains problematic. As a matter of fact, explaining why private property exists is not the same as analyzing why it is legitimate (and thus immune to manmade rule making). In particular, it raises the problem of specifying who decides about efficiency: the homesteader or the ruler? As result, different perspectives produce different answers.

Finally, the fundamentalist approaches try to justify private property by resorting to religion, or to natural rights, or to expedience (which differs from consequentialism). As we observed, religion is problematic, in that it has no universal value. If one justifies private property by appealing to faith, different religious views can lead to radically different conclusions. Natural rights are different, since the various approaches underscore one or more natural traits of all human creatures and give birth to different theories of property in accord with human nature(s). Hence, if one assumes that all individuals share a set of natural rights, then private property is inviolable insofar as it is recognized as a natural right or strictly derived from a natural right. In a similar vein, if freedom from aggression is recognized as a natural right, private property is legitimate as long as it does not involve aggression (homesteading doesn't, by definition) and as long as appropriation by the comers does not imply violence (voluntary exchange doesn't). However, if one has doubts about the "natural" nature of private property, or about the general validity of the freedom-from-coercion principle, then the legitimacy of this institution becomes questionable. By contrast, expedience rests on identifying the presumption of liberty as the simplest way of organizing a community (De Jasay 2005). This presumption

leads to the finders-are-keepers rule and requires the second comer to challenge the incumbent owner. The reader might notice three interesting aspects. According to this vision, (1) the origin of private property rests on a negative (*ex post*) notion of legitimacy; (2) the presumption of liberty is not a moral argument in favor of liberty, but rather an operating principle that minimizes costs; and (3) the negative notion of legitimacy ensures that the burden of proof lies with the challenger, a choice that has no moral content, but enhances social cooperation.

An Extension to Intellectual Property

Theories about the foundations of private property have usually focused on natural resources and the fruits of men's activities. In recent times, however, considerable attention has been devoted to the property rights on intangibles, with particular reference to two areas: information and patents. In all these cases, the research agendas share one common feature and are relatively simple.

In contrast with what happens in the realms of natural resources and material goods, intangibles are frequently characterized by the presence of free riding, i.e., by the possibility that individual A benefits from the activity of individual B, regardless of whether A and B are bound by a contract. Knowledge, information, and ideas are typical examples. Hence, when free riding occurs, A's welfare increases thanks to B's labor and talents, regardless of whether B agrees or feels slighted. This raises a question. Is free riding a problem or perhaps a crime against private property? Or is it just a fact of life, which some people consider harmless and others undesirable?

The research agendas follow the lines of thinking suggested by the questions above, depending on whether one believes that free riding should be restrained or, rather, freely allowed. One approach alludes to fairness/envy. These notions play a significant role when some agents have privileged access to relevant information and exploit this privilege in dealing with allegedly uninformed counterparts. Those who lament that uneven information amounts to unfairness require that

the informed disclose everything they know, except for situations in which they actually bought or researched the information from which they benefit or in which the information is easily accessible to anybody (in which case there would be no privilege). Legislation against insider trading follows this view: it is all right if individual A reads the business press or carries out extensive research about company Z and decides to operate accordingly on the stock exchange. However, A cannot exploit the information he obtains if he enjoys an allegedly privileged position. In the case of insider trading, the privilege consists in being an employee or an administrator of Z.

By contrast, the legislation regarding patents exemplifies other views on property rights. One is based on the claim to self-ownership and one on consequentialism. The argument stemming from the assumption of self-ownership rests on the fact that the mind is part of one's own self and that, therefore, what is produced by one's mind is necessarily an extension of the individual, who homesteads it. Put differently, the second inventor/author/discoverer cannot claim property rights on something that others have already removed from the state of nature, a state of nature that includes knowledge, skills, and artistic concepts that humankind ignores. Although this thesis has merit, it runs into a number of problems, which we shall only mention. Most innovations are based on earlier insights and discoveries. This approach would require that all inventors track – and ask permission to – all the legitimate owners of the knowledge that the current inventor is using. Moreover, the difference between a new invention, a marginal improvement on an idea already existing, and the bare use of an existing idea is frequently far from clear. Finally, the very act of exercising one's intellectual abilities hardly justifies preventing other individuals from using their own intellectual abilities, which include thinking, observing, and possibly reproducing. Of course, this line of reasoning resonates with the presumption of liberty mentioned in the previous section, a presumption often used as an argument against the existence of property rights on intangibles and thus against the legitimacy of patents. In other words, one may argue that the theory based on

the extension of one's self regards the appropriation of the result one obtains by using his talent, his labor, his knowledge, and his imagination. Yet, a result is not a process. Put differently, discovering a process and making use of it do not remove knowledge from the state of nature. It merely makes knowledge accessible to the inventor and to the rest of the community. If this is true, one can thus conclude that enriching the state of nature does not involve homesteading and that involuntary altruism is not a source of rights.

The previous comments help understand why the current legislation on intellectual property rights is founded on consequentialism rather than on philosophical theorizing. As it often happens in law-and-economics debates, the debate presents different views. We list two of them. On the one hand, a large portion of the literature neglects to discuss the nature and foundations of property rights on intellectual property. Rather, it maintains that governments driven by utilitarian principles are justified in enforcing property rights on intangibles in order to compensate their authors for the damage suffered at the hands of free riders. In other words, the origin of intellectual property rights is the government, which assigns them in the common interest. The consequentialist counterargument is that too much protection awarded to a set of inventors may prevent potential competitors from improving on the existing technology and developing new insights. The upshot is that the presence of free riding justifies patents and other barriers to entry. However, these barriers should expire after some time and allow new competitors to enter the scene at a relatively low cost.

Yet, there is also a second and more recent consequentialist perspective. As mentioned at the beginning of section “[Recent Free-Market Agendas: From Demsetz to De Jasay](#),” some eminent scholars argue that private property originates as a response to scarcity. In other words, private property is legitimate because it is an efficient way of exploiting scarce resources: it enhances exchange, and it allows individuals to distribute consumption over time, possibly taking into consideration also the potential benefits enjoyed by future generations. Intangibles,

however, do not present a problem of scarcity. The use of knowledge by one individual does not prevent other individuals from exploiting that very knowledge. Hence, absent scarcity, private property has no reason to exist, and the debate on the origin of private property in the realm of intangibles is moot. From a normative viewpoint, therefore, patents have no legitimacy.

Privatization

Brady P. Gordon
Trinity College, University of Dublin, Dublin,
Ireland

Abstract

Privatization as a tool for economic management emerged in the 1970s and 1980s in response to the decline of Keynesian economics and the collapse of communism and has expanded to become a pillar of public policy in all of the world's major economies. The economic benefits of privatization emerged out of new economic theories which applied long-established principles of market failure to weaknesses in public sector economic governance. It is seen as a useful way of increasing efficiency by introducing private competition to otherwise inefficient, monopolistic, and politicized operations in the public sector. Since the late twentieth century, privatization outcomes have been increasingly recognized as context-dependent and socially contested, but privatization remains a pervasive and useful instrument of government policy in pursuit of a wide range of economic and social aims.

Definition

Privatization describes the transfer of government assets or functions from public to private ownership. Privatization is the opposite of nationalization, in which governments acquire privately owned assets or operations.

Types of Privatization

Privatization encompasses four broad types of transactions:

Denationalization consists of the divestiture of state-owned assets to private ownership, typically through sale or lease. The first large-scale privatization campaigns at state level consisted largely of denationalization. These were led by the UK, the USA, and Chilean governments in the 1980s and saw the denationalization of many public utilities (i.e., industries in the telecommunications, energy, transportation, sewage, and water sectors), traditionally associated with the public sector. Denationalization allows governments to expose what might be inefficient, subsidized and politicized government-owned monopolies to private competition, and increase short-term revenues.

Concessions consist of the granting of a legal right to fund or construct an infrastructure project and/or operate a public service. The most common example of a concession is the right of a private company to construct and operate a toll road or bridge. Concessions allow governments to engage in public works projects which might otherwise be unaffordable or politically infeasible for the government.

Outsourcing or tendering consists of contracting with a private entity to finance or deliver a public service that had hitherto been carried out in-house by a branch of the public service. Tendering processes are often considered to allow governments greater control over privatization outcomes than simple divestment, since it allows the government to set minimum service standards and multiple criteria as the basis for competition. Outsourcing may occur for

entire services or it can be introduced at specific levels of the supply chain in order to open financing, production, or service provision stages to private competition. This may be useful where a government wishes to retain control over the function as a whole. For example, public policy may require government control over the provision of health care, but the operation of specific ambulance services or the construction of hospitals may be outsourced to the private sector without sacrificing that commitment. In the USA, federal and state governments frequently outsource even core state functions such as military and security services.

Deregulation consists of the opening of state-operated or state-controlled activities to private sector competition, allowing the government to retain its ownership but exposing the public entity to increased competition.

In addition to the main categories of privatization, there are also innumerable intermediate forms of privatization. For example, these might consist of public-private partnerships (PPPs) or private finance initiatives (PFIs), wherein an asset is financed entirely or partially by the private sector and the investment is recouped either through reimbursement from the government or through the accrual of profits from the operation of the service.

Historical Development of Privatization

For most of the twentieth century, until the 1970s, public ownership of key industries was a basic tenet of economic policy in each of the world's major economic blocs. In particular, public utilities such as energy, telecommunications, water, sewage, and transport were nearly universally state-owned industries. This began to change in the 1970's and 1980's, when new economic theories began to apply principles of market failure to weaknesses in public management, and the socialist economies of Central and Eastern Europe fell into rapid decline. By the end of the twentieth century, privatization had become a prevalent

feature of public service provision in all of the world's major economies. Privatization is now recognised as a useful economic tool with different costs and benefits depending on the economic and social context.

In the liberal market economies of the USA and Western Europe, Keynesian macroeconomic theory prevailed from the late 1930s until the late 1970s. Keynesian economics emphasized the influence of aggregate demand on economic output and therefore the facilitating potential of government intervention in the economy. Keynesianism reached its zenith at the 1944 Bretton Woods Conference with the establishment of the global monetary system, the International Monetary Fund (IMF), and the World Bank. Following the "total war" state mobilizations of World War II, most major manufacturing and utilities industries in western economies were state-owned, and it was widely accepted that key industries should remain so. There were some important instances of privatization during this period, including the privatization of the British steel industry in the 1950s, and coordinated divestitures by the West German government in the 1960s (e.g., the sale of a majority state in Volkswagen in 1961). For the most part, however, public utilities and other important industries remained state-owned. This consensus was entrenched further as increasing prosperity after World War II led to the expansion of welfare states and social-market economies around the world. Keynesian economics informed the management of western market economies for much of the postwar economic expansion.

In Eastern and Central Europe, the rise of socialism sometimes led to near-total appropriation of enterprise and centralised planning of economies by the state during the postwar period. The constitutions of socialist countries based on the 1936 USSR Constitution, for example, stipulated that all productive assets (including firms) were property of "all the people" (i.e., the state). Private markets were severely constricted in eastern-bloc countries.

In South America, Asia, and Africa, encouraged by the new global Keynesian institutions and governments of both socialist and capitalist

countries, developing nations equally saw state control and investment as the best way to achieve fast “catch up” in modernization and industrialization (Parker 2000).

Until the 1970s, economic theorists in all the world’s major economic blocs were therefore primarily concerned with identifying imperfections in private markets and making adjustments through public intervention. The reign of Keynesianism in the west and socialism in the east meant that economic thought to the 1980s was dominated by the literature on market failure.

Privatization only began to take root in developed countries during the ascendancy of neoliberal economic theory in the late 1970s and early 1980s. Applying lessons of the market-failure literature to the economic performance of states, economists began to identify failures in the government’s ability to perceive public wants, and further weaknesses in incentives to satisfy those wants efficiently. Economists such as Ronald Coase and Harold Demsetz questioned the prevailing logic that the mere existence of market failures warranted government intervention. Coase argued against government intervention without first analyzing whether such intervention would improve economic outcomes (Coase 1960), and Demsetz identified problematic inefficiencies and information asymmetries in government-managed organizations (Demsetz 1969, 1968). The essential defense of privatization which emerged from the literature was that the private sector was capable of providing public goods and services more efficiently than governments due to the disciplining effect of competition and profit motives. Transferring public functions to private, for-profit enterprises instilled incentives to cut costs and produce goods in response to demand. Exposure to competition and supply and demand principles were predicted to improve efficiencies in both production and allocation.

Neoliberal economic doctrines began to gain political traction in developed economies in response to the failure of Keynesian policy to deal with the economic malaise and stagflation of the 1970s. It was first enacted at the level of national policy in the UK under the administration of Prime Minister Margaret Thatcher (1979–1990),

in the USA under the administration of President Ronald Reagan (1980–1988), and in Chile under the administration of President Augusto Pinochet (1974–1990). This was followed by other Western European economies within a decade. In the European Community in the 1990s, the abolition of customs barriers, the liberalization of national markets, common merger controls, and prohibitions on state aid facilitated the entry of private operators to areas that had previously been dominated by governments (Parker 1998). New European rules implied limits on public interventions. Portugal and France, for example, were required to amend their privatization legislation to allow foreign private investment.

In the transitional economies of Central and Eastern Europe, privatization took root as the result of an altogether different process: The collapse of Communism. Following the collapse of the USSR in 1989, privatization became a pillar of state policy in transitional economies. In Russia itself, two major waves of privatization occurred: The first wave, from 1992 to 1994, saw major state enterprises converted to joint-stock companies and put up for public auction, with Russian citizens given vouchers redeemable for stock in the new companies. A second wave of privatization saw the divestment of much of the energy and telecoms sector to private investors in the late 1990s and early 2000s (Leonard and Pitt-Watson 2013). By 1999, only 4% of registered companies in Russia were owned by the state (Munkholt 2000). Similarly, in post-Warsaw pact and other socialist countries, privatization occurred as both an economic and political reaction to the fall of communism. After the collapse, 90% of industrial capital in Eastern Europe remained in public hands (Lipton and Sachs 1990). Privatization thereafter took a variety of forms, often appearing as employee share purchases, public vouchers, or sales to cooperatives and private shareholders. Economic aims included increased efficiency generally, but often also aimed at increasing economic trade with Western Europe. Political aims included returning property to private owners who might have been deprived of it by the nationalization process under socialist governments.

In developing and emerging countries in Asia, Latin American, and Africa, impetus for privatization derived from two significant sources: As a precondition of foreign investment from developed market economies and as a condition for international aid and structural adjustment programs. Conditionality for financial assistance from the IMF, World Bank, and developed-country governments frequently requires states to meet certain objectives of economic liberalization or to pursue debt sustainability by denationalizing assets. Privatization policies have also often been used to counteract a perceived culture of political instability and to signal a commitment to free enterprise. At the dawn of privatization, between 1988 and 1993, the value of privatizations in developing countries reached US \$96bn (World Bank 1995).

China has embraced limited privatization as part of its “Socialist Market System”, while keeping political control and ownership of large, key industries in the economy. Yet it has not been immune to the growth of privatization. From 1978 to 1991, the state’s share in industrial output fell from 77.6% to 52.9% (Wang 1994). In 1995, the State Council endorsed a policy of maintaining state control on large industries and allowing competition in small industries. The role of the state in industry has gradually declined as part of a measured and evolving process of opening up certain sectors of the economy to international investment without compromising political control of key economic sectors.

By the end of the twentieth century, the use of private actors in facilitating the operations of government had become ubiquitous in government policy around the globe. Privatization is no longer the exclusive domain of certain political systems or poles of the political spectrum. The discussion of governmental functions in liberal market economies is now suffuse with market-style language. Public service has been increasingly submitted to what have been called “New Public Management” regimes based on market-based theories (Hughes 2003). Private actors operate prison and immigration systems, determine regulatory standards for key industries, provide health care, and even conduct policing and military operations on behalf of governments.

Within this new global paradigm, the outcomes and theory of privatization have also begun to come under criticism. The results of privatization have often been mixed and context-conditional. Privatization has generated political opposition in many countries, and the theoretical tenets have come under challenge. In theory, policy, and practice, the extent to which privatization should be enacted in each country has become a much more nuanced and particulate debate.

The Economics of Privatization

The rationales for privatization are invariably couched in terms of economic efficiency. A number of rationales emerge from the literature (Parker 2000):

- Increased economic efficiency by introducing private competition and profit motives to what might otherwise be inefficient, monopolistic, and politicized operations under the public sector
- The reduction of government debt by selling financially burdensome assets or operations
- Increased welfare through increased responsiveness to supply and demand and cheaper goods from competition
- The avoidance of capture by politicians overseeing the provision of services by special interest groups such as trade unions or professional bodies
- Cost savings in accomplishing public works by allowing private investment to supplement or displace government financing
- Increased private ownership of capital and the fostering of liberal markets
- The attraction of mobile capital and foreign direct investment in an increasingly globalized world

Broadly, each of the efficiency arguments for privatization is based on two tenets of economic reasoning: (1) Efficiency gains from competition between firms and (2) efficiency gains from information and incentives within private firms (Dunsire et al. 1988; Vickers and Yarrow 1988). Both sources of reasoning stem from the premise that governments do not always pursue maximum

welfare and that imperfections in markets do not automatically justify government intervention.

Economic Efficiencies from Product Market Competition

Economic efficiency is comprised of allocative efficiency and production efficiency. Allocative efficiency occurs when producers produce only those types of goods that are useful and in demand in society, and where the price is equal to marginal cost. In essence, it is concerned that resources are not expended on less-optimal products, and that the most optimal distribution of resources is achieved. Production efficiency occurs when products are created using the least resources possible for the most efficient level of production. Production efficiency in turn has two constituent elements: technical efficiency and price efficiency. Technical efficiency is concerned with the effectiveness of inputs in creating an output. So, for example, a firm which employs too many workers or has underutilized equipment is technically inefficient. Price efficiency is the degree to which a price reflects all available supply and demand information. So, for example, charging a high price for a product that is in low demand would be price inefficient.

Under conditions of competition, firms will seek to optimize allocative and production efficiency, and price will reflect the most efficient marginal costs available. In essence, firms will strive to create the most useful products for the least cost, and charge prices that reflect supply and demand, maximizing economic well-being (Kirzner 1997). Without competition, a firm may restrict output and raise prices. It will not need to pursue technical or price efficiency. Where the monopoly is state-owned, this applies to governments. Governments which own firms have incentives to eliminate competition by regulating the market, subsidizing inefficient industry, or erecting legal barriers to entry (Littlechild 1986).

Efficiencies from Private Firm Ownership

The second source of efficiency from privatization derives from principal-agent theory. Principal-agent theory concerns the information asymmetries

between principals (owners) and agents (managers) of firms. Under this theory, the private sector is considered to have more effective mechanisms of control in place between those who own the firm and those who drive its performance. The first and most obvious reason for this is that incentives for management performance in the private market are often unrestrained by politics and public law. Management may be generously incentivized or quickly demoted more easily than in the public sector, where set pay scales, public unions, and political costs may restrict action. Secondly, a private capital market is considered to have more effective means of control over managers. Managers and boards of directors can be pressured to resign by shareholders. A firm which is losing the value of its shares may see investors sell their shares, further precipitating a drop in the firm's share price. If the share price drops low enough, the firm becomes susceptible to takeovers by more efficient firms, who may then purchase the firm's asset and turn them to more productive uses. In essence, it is argued that inefficient management cannot survive in the private market.

In the public sector, agents are responsible to politicians. The literature on public choice indicates two problems with governments as principal: The first is that the objectives of government are some combination of social welfare, the politician or government's own personal goals, and the aims of special interests groups (Niskanen 1971). Even if weighted only slightly towards the latter two goals, this represents a suboptimal welfare result. Politicians may be subject to political capture and require firms to pursue secondary objectives such as industry employment, high wages, and other aims which may run counter to productive efficiency. These wider social objectives may genuinely contribute to the public welfare; however the literature on public choice suggests that governments are no less susceptible to rent-seeking than private monopolies (Buchanan 1972). For example, a politician elected due to the support of labor interest groups may be insulated from citizen pressure and instead be incentivized to promote high wages in the industry instead of efficient outputs that benefit public welfare as a whole. The second problem is

that, even if the government solely pursues the maximization of efficiency, governments lack information on demand and supply costs. Only under conditions of competition is demand information readily available.

Legal Controls and Methods of Privatization

The divestiture or delegation of basic public services to private actors can raise legal questions both as to legal methods of control on the actions of government and what legal forms privatization may take.

Legal Controls on Privatization

Privatizations are typically subject to three types of legal control: Constitutional law, administrative law, and international or human rights law.

Constitutional law places limits on the existence and exercise of public power. This can include limits on the government's power to privatize. Article 34 of the French Constitution of 1958, for example, states that rules governing the transfer of public assets to the private sector shall be set by law. Privatizations are therefore required to be approved by the legislature. The constitutional principle of equality among citizens and Article 17 of the Declaration of Human Rights (which requires just compensation for expropriation) has been held by the French Constitutional Council to prohibit the sale of public assets at less than the real value. Privatization transactions are therefore justiciable both on the basis of the separation of powers and administrative value. In other countries, such as the UK, the doctrine of parliamentary sovereignty and the discretionary powers of government mean that divestitures by either the legislature (by statute) or the executive (by contract) will not be subject to judicial review without an explicit statutory basis. In the EU, the European Court of Justice has long accepted the existence of an inherent power to delegate where necessary to exercise a power conferred by the Member States,

subject to the limit that privatizations on that basis cannot exceed the limits of the power conferred (*Meroni v. High Authority* [1957–58] ECR 133). In the USA, the Fifth and Fourteenth amendments to the US Constitution contain “due process” clauses which stipulate basic elements of fundamental fairness such as the opportunity to be heard and impartiality in decision-making. The courts have derived a constitutional doctrine of non-delegation from these clauses that requires governments to comply with due process and the separation of powers when delegating.

Administrative law seeks to ensure fairness and compliance with the rule of law in the exercise of state power. In both civil law and common law countries, the legislature may set out detailed codes on administrative procedures and public decision-making. In the USA, federal and state legislation encompass a range of procedural acts. The Federal Procedure Act 1946, for example, offers equal or greater procedural protection than even the due process clause of the constitution. In the EU, conditions and limits on the delegation of state power are regulated in detail by Financial Regulation 1081/2010 [2010] OJ L311/9, which sets out the tasks that can be delegated to private entities or agencies. In the USA and UK, the common law principles of judicial review grant the courts a jurisdiction to review the actions of government decision-makers against standards of procedural unfairness, transparency, bias, and rationality (Taggart 1997).

International and human rights law seeks to protect individuals against the inappropriate use of state power. This becomes particularly relevant to privatization when human rights principles contain procedural protections. For example, Article 6 of the European Convention on Human Rights (ECHR) enshrines the right to a public hearing before an independent and impartial tribunal where civil rights are being determined. It is not difficult to imagine how privatization of a social function such as welfare or public housing could have the potential to deprive the individual of the right to an impartial tribunal against determinations of

their civil rights by the private body. The existence of profit motives of a private operator may provide an incentive to disqualify recipients of welfare or housing benefits, for example. Indeed, in *Feldbrugge v. Netherlands* (1986) 8 EHRR 425, the European Court of Human Rights held that such benefits may give rise to civil rights.

Legal Methods of Privatization

In legal terms, the three main techniques for privatization are legislation, contracts, and legal grants (Donnelly 2007). Each method is subject to a different mixture of legal controls in each state.

Privatization by legislation is, in legal terms, perhaps the most conventional method for privatization. Legislative acts are typically justifiable under general constitutional law principles and are therefore likely to be subject to judicial review principles. The same will generally be true of a privatization engaged in by the executive, subject to rules set out in legislation. In many jurisdictions, however, there are also countervailing limits to the legal control of privatization by legislation. In the UK, the doctrine of parliamentary sovereignty precludes judicial review of legislative acts unless provided explicitly by statute. In practice, statutes granting executive powers are typically drafted broadly and are unlikely to preclude privatization where it may be necessary for the function given.

Privatization by contract transfers the source of the private entity's legal responsibility from an act of the legislature to a private contract. Whereas executive and legislative action is bound by constitutional, administrative, and international law, a private party governed by private contract is typically governed by the terms of the contract. In the UK, decisions by private actors operating under contract are not typically subject to judicial review and administrative law principles, even when exercising a public power (Freedland 1994). In the USA, the definition of "state actor" to which constitutional and administrative procedural rules apply has evolved to exclude most private

actors acting under a contract. Private actors are exempt from disclosure, oversight, bias, and ethical obligations which apply to public bodies under the US Code of Laws, for instance. Similarly, international human rights obligations such as the ECHR bind state parties only, despite the fact that private entities exercising state power may exercise the same capacity to interfere with individual rights. In the UK, for example, despite the fact that the Human Rights Act 1998 applies to "functions of a public nature", the public or private nature of the entity has tended to predominate, rather than its function. Since the legal controls on the private actor are often limited to the scope of the contract, its drafting will have a significant impact on the government's ability to control outcomes. On one hand, government contracts typically fall within the scope of public procurement regulations, and therefore may allow or require governments to include public-service objectives in pecuniary contracts. On the other hand, many government services are highly variable and it may be inappropriate to limit the criteria for performance evaluation. A contract which pays a prison service on a per head basis, for example, may instate a perverse incentive to extend sentences. Yet the more complex the contract, the more difficult the privatization is to monitor, and the less benefit is gained from privatization.

Legal grants consist of the granting of a legal right or funding to build or operate an asset. In contrast with contracts, grants are typically governed by authorizing legislation and often fall outside the scope of legislated procurement regimes. There is often a broader latitude given to the recipient as to how to achieve the aims of the privatization. This can result in an arbitrary difference in legal treatment between contracts and grants (Donnelly 2007).

Criticisms of Privatization

Economic Criticisms

Privatization theory has come under pressure from the emergence of new theories such as New

Institutional Economics theory, which question the predictive power of privatization models and attempts to demonstrate that the optimal allocation of functions cannot be determined a priori in all cases. Privatization is not universally beneficial, and the optimum allocation of ownership often depends on the economic and social attributes of a specific country. Some contemporary economists, such as Joseph Stiglitz, argue that government can generally outperform private enterprise in economic outcomes (Stiglitz 1995). Critics argue that privatization should only take place where the market could perform as well as the benevolent government (Sappington and Stiglitz 1987). This criticism centers around two main heads:

First, markets are often imperfect, and privatization only generates benefits under specific market conditions. The choice is not always between government monopoly and fully competitive capital markets with effective competition. Many state-owned industries maintain large economies of scale (such as rail networks or telecommunication towers) which they then take with them to the private market to create a private monopoly. There is also evidence that private monopolists may be more harmful than public monopolists (Pint 1991). The OECD concludes that private sector monopolists are much more efficient under conditions of competition but also much better at extracting rents under monopolistic conditions (OECD 2000). They may also be less susceptible to regulation: attempts to regulate them may simply result in the private firm passing on the cost of regulation to consumers without bearing any cost itself (De Fraja 1993). Some economists argue that competition is the crucial factor in efficiency, rather than the public or private nature of the owner (Milward and Parker 1983; Vickers and Yarrow 1988).

Second, capital markets may not make for more efficient principal-agent control. Private sector management may still be able to pursue their own objectives to a large degree without shareholder reaction, and a loss of shareholder value may not necessarily lead to takeovers or share sell-offs.

The empirical outcomes of privatization have not always shown efficiency improvements, particularly where privatization has merely resulted in the transfer of a public-sector monopoly to a private-sector monopoly. While there is strong evidence that privatization lowers prices and improves services where markets work effectively, the outcomes can often be the opposite where the privatization did not result in competition (OECD 2000). In other cases, critics have argued that state-owned assets and rights have been sold at an under-value, with no residual government ability to regulate the industry and ensure pareto outcomes for the citizens. The optimum allocation of private and public control is now a matter of theoretical, empirical, and political debate in individual countries and economies. Economists in favor of privatization have continued to argue that the private sector is a more efficient provider of most government functions. For example, Megginson observes that “private ownership must be considered superior to state ownership in all but the most narrowly defined fields or under very special circumstances” (Megginson 2005). Yet other authors argue that privatization increases costs just as often as it reduces them (Brudney et al. 2004). In a survey of the literature, Parker concludes “Empirical evidence, like the economic theory, does not allow us to be confident of predicting accurately the outcome of any privatization on corporate performance” (Parker 2000).

Legal Criticisms

While the scope of public law varies between jurisdictions, government action is often subject to legal constraints under constitutional law, administrative law, and human rights law, which private actors are not. This may allow public actors to divest themselves of their legal obligations. For example, under EU law, the actions of public institutions may be challenged on the basis of the principles of proportionality and non-discrimination, where private institutions may not. In the USA and the UK, the common law principles of judicial review grant the courts a jurisdiction to review the actions of government decision-makers against standards of unfairness,

transparency, bias, and rationality (Taggart 1997), but common law judicial review does not apply to private actors. The principle of bias, for example, forms part of the natural law principles of procedural fairness at common law. It states that where a decision-maker has a pecuniary interest in a decision, the decision may be void for bias. Yet for-profit private actors (for example, particularly those responsible for social welfare or prison systems) will nearly always have a pecuniary interest in the outcome of decisions which it has been delegated.

In civil law countries as well as common law countries, public law sets out detailed codes on administrative procedure and decision-making, but private law remains a matter of contract. This makes courts and legislators slow to recognize and enforce public law duties on private parties in most jurisdictions, even when those private parties are wielding governmental power (Donnelly 2007). Even under the most effective international human rights regimes, such as the European Convention on Human Rights, individual human rights are enforceable only against the state save in exceptional or indirect cases. Such regimes do not typically apply to the actions of private parties, despite the fact that private parties exercising state power may enjoy the same capacity to interfere with individual rights.

Political Criticisms

Political opposition derives primarily from five outcomes: (1) Private restructuring of labor markets and labor retrenchments may result in worker vulnerability and increased unemployment; (2) privatization may result in the discontinuation of less-profitable services; (3) consumer cost increases may result from the withdrawal of government support or private market imperfections; (4) governments may lose control of outcomes in which there is a strong public interest; and (5) privatization may sacrifice the long-term value of assets for short-term gain, because while there are inevitably a finite amount of public assets, there is an infinite capacity for debt growth.

Political opposition therefore derives from both empirical and ideological observation. Underlying each of these criticisms is the

implication that the treatment of citizens as consumers is often inappropriate. First, at an ideological level, citizenship may imply something more than consumerism – it implies a stake in the state itself. For example, as citizen-consumers, the electorate may accept the privatization of postal services provided that efficiency gains are demonstrated, but the electorate as citizens may not accept the privatization of health or military services, regardless of efficiency. The National Health Service in the UK is an example of a public asset that is unlikely to be privatized due to strong public support. Second, at an empirical level, consumers exercise their influence on the state through the exercise of choice. Yet when it comes to public services, citizens will not often have a choice. Welfare recipients or those needing immediate health care, for example, may not have a choice as to the most efficient provider.

Product Promotion Strategy

► Promotional Effort

Productivity and Growth

Jaime Vallés-Giménez and Anabel Zárate-Marco
University of Zaragoza, Zaragoza, Spain

Abstract

Economic growth is a long-run process that occurs when an economy's potential output increases, and it can be measured by the

product method, the income approach or the expenditure method. Actual growth is the percentage annual increase in national output. Potential growth is the speed at which the economy could grow, i.e. the percentage annual increase in the economy's capacity to produce and it can be shown by an outward shift in the economy's production possibility frontier. The theory and empirical studies suggest that potential economic growth is associated with the increase in the use of factors of production (capital, labor, energy, etc), but primarily to increases in productivity or efficiency with which these factors are used, through advances in labor skills and organization of production or improves in technology. Productivity and economic growth are then closely linked because economic growth occurs when productivity increases to allow for such growth. Productivity is therefore the cornerstone of economic growth.

Productivity is an indicator of the efficiency of production and can be defined as the ratio of output to inputs in production. Higher productivity means that the economy can produce more goods and services at a lower cost per unit. This will help to reduce prices and increase consumer welfare and living standards, because more real income improves people's ability to purchase goods and services, enjoy leisure, improve housing and education and contribute to social and environmental programs. Higher productivity increase total output from the scarce factor resources, causing an outward shift of the production possibility frontier. Productivity also affects our competitive position: the more productive we are the better we are able to compete on world markets. Productivity growth also helps businesses to be more profitable. There are broadly two ways of measuring productivity. On one side are the partial productivity measurements that relate to an input (labor, capital, etc), and on the other side it is a measure of total factor productivity (TFP) or multifactor productivity (MFP), which measures the effects in total output not caused by measured inputs of labor, capital and intermediate outputs.

Definitions

Economic growth is a long-run process that occurs when an economy's potential output increases, i.e., as economy's ability to produce goods and services rises.

Productivity is an indicator of the efficiency of production.

Concepts and Connections Between Growth and Productivity

The fruit of economic activity is the amount of goods and services produced by labor, capital, and other inputs. So arguably, **economic growth** is the increase in the market value of the goods and services produced by an economy over time. It is conventionally measured as the percent rate of increase in real gross domestic product, or real GDP, i.e., $(\text{real GDP}_t - \text{real GDP}_{t-1}) / \text{real GDP}_{t-1}$.

Since GDP is a macroeconomic variable, i.e., it is the result of multiplying the quantities of goods and services produced in one country by their prices, we will only have a proper idea of the growth of an economy's production if we eliminate the distorting effect of inflation on the price of goods produced, and the evolution of real output is analyzed.

Another element to consider in economic growth is the increase in population. Only if the population increase is known can it be determined whether the per capita product increases or not. For this reason, of more importance is the growth of the ratio of real GDP to population (real GDP per capita).

On the other hand, as the GDP figures of each country are measured in its local currency, they have to be converted into a common currency (e.g., dollars or euros) at the current exchange rate, to be able to be compared. But the exchange rate may be a poor indicator of the purchasing power of the currency at home. To compensate for this, GDP can be converted into a common currency at a *purchasing-power parity rate*. This is a rate of exchange that would allow a given amount of money in one country to buy the same amount of goods in another country after

exchanging it into the currency of the other country.

Besides this method of measuring GDP, known as the *product method*, GDP can be calculated in other two different ways. The production of goods and services generates incomes for households in the form of wages and salaries, profits, rent, and interest. Therefore, GDP can also be calculated by adding up all of the income received by labor and other inputs in the economy. This is known as the *income approach*. The third method, expenditure method, focuses on the expenditures necessary to purchase the nation's production by different groups in the economy. The four main components are consumption expenditures by households, gross private investment spending principally by firms, government purchases of goods and services, and net exports (exports minus imports). Because of the way the calculations are made, the three methods of calculating GDP must yield the same result.

It is essential to distinguish between actual and potential economic growth. Actual growth is the percentage annual increase in national output: the rate of growth in actual output (GDP). Potential growth is the speed at which the economy could grow. It is the percentage annual increase in the economy's capacity to produce: the rate of growth in potential output. An increase in an economy's productive potential can be shown by an outward shift in the economy's production possibility frontier.

If the potential growth rate exceeds the actual growth rate, there will be an increase in spare capacity and probably an increase in unemployment: there will be a growing gap between potential and actual output. To close this gap, the actual growth rate would temporarily have to exceed the potential growth rate. In the long run, however, the actual growth rate will be limited to the potential growth rate. Although growth in potential output varies to some extent over the years – depending on the rate of advance of technology, the level of investment, and the discovery of new raw materials – it nevertheless tends to be much more steady than the growth in actual output. Actual growth tends to fluctuate. In some years, countries will experience high rates of

economic growth. In other years, economic growth is low or even negative. This cycle of booms and recessions is known as the business cycle or trade cycle. The business cycle moves up and down, creating fluctuations around the long-run trend in economic growth.

Anyway, these measures of growth do not determine economic development as this is a more complex concept as it has social connotations also related to the improvements of living standards in the country. They ignore the distribution of income. Although per capita real income may be increasing in a country, this does not necessarily mean that all the inhabitants of that country are benefiting from this improvement. Maybe along with the growth of real income it takes place a change of income that impoverish certain people while others enjoy her growth above average. While economic growth is necessary, it is not sufficient for progress on reducing poverty. For this reason, the economic growth may be a poor indicator of society's well-being.

Moreover, it does not compute the human costs of production. If production increases, this may be due to technological advance. If, however, it increases as a result of people having to work harder or longer hours, its net benefit will be less. Leisure is a desirable good and so too are pleasant working conditions, but these items are not included in the economic growth figures.

Another problem in the computation of economic growth is some external benefits or costs that are not included in GDP statistics. For example, growth has the disadvantage that can both create negative externalities, e.g., higher levels of noise pollution and lower air quality arising from air pollution and road congestion and causes depletion of resources. And finally, GDP only measures the market economy, thereby excluding "do-it-yourself" and other home-based activities as well as the underground economy, so the GDP statistics understate the true level of production in the economy.

Since the pioneering work of Solow (1956), the theory and empirical studies suggest that potential economic growth is associated with two factors: the increase in the use of factors of production (capital, labor, energy, etc.), but

primarily the increase in productivity or efficiency with which these factors are used, through advances in labor skills and organization of production or improvements in technology. Productivity and economic growth are then closely linked because economic growth occurs when productivity increases to allow for such growth. Productivity is therefore the cornerstone of economic growth.

Productivity can be defined as the ratio of output to inputs in production. It is an average measure of how efficiently goods and services are produced. Higher productivity means that the economy can produce more goods and services at a lower cost per unit. This will help to reduce prices and increase consumer welfare and living standards, because more real income improves people's ability to purchase goods and services, enjoy leisure, improve housing and education, and contribute to social and environmental programs. Higher productivity increase total output from the scarce factor resources, causing an outward shift of the production possibility frontier. Productivity also affects our competitive position: the more productive we are the better we are able to compete on world markets. Productivity growth also helps businesses to be more profitable.

There are broadly two ways of measuring productivity. On one side are the partial productivity measurements that relate to an input (labor, capital, etc.), so we can say that there are so many measurements of productivity as resources used in production. This partial productivity has usually been measured in terms of labor, by the availability of data. Labor productivity is then the value of goods and services produced in a period of time, divided by the hours of labor used to produce them. In other words, the labor productivity measure the output produced per unit of labor, usually reported as output per hour worked or output per employed person.

However, partial productivities do not show overall efficiency of the use of all the resources, so it is important to have a simultaneous measurement of the efficiency of the totality of resources, i.e., a measure of total factor productivity (TFP) or multifactor productivity (MFP). TFP measures

the effects in total output not caused by measured inputs of labor, capital, and intermediate outputs. If all inputs are accounted for, total factor productivity (TFP) represents improvements in ways of doing things, that is to say, it can be taken as a measure of an economy's long-term technological change or technological dynamism, which is the primary source of real economic growth. In the short term, however, also reflect unexplained factors such as cyclical variations in labor and capital utilization, economies of scale, and measurement error. Total factor productivity is the most commonly known and widely used method of productivity measurement. However, TFP cannot be measured directly but is a residual. It accounts the residual growth that cannot be explained by the rate of change in the inputs.

Sources of Productivity and Economic Growth

Despite the lack of a unifying theory, there are several partial theories that discuss the role of various factors in determining long-term economic growth. Two main strands can be distinguished. The neoclassical model based on the growth model of Solow (1956) has emphasized the importance of investment. And the more recent theory of endogenous growth developed by Romer (1986, 1990) and Lucas (1988) has drawn attention to human capital and innovation capacity. Furthermore, important contributions on economic growth have been provided by the cumulative causation theory of Myrdal (1957) and by the New Economic Geography school of Krugman (1991). These two schools assert that economic growth tends to be an unbalance process favoring the initially advantaged economies. In addition, other explanations have highlighted the significant role that non-economic (in the conventional sense) factors play on economic performance.

The theoretical and empirical studies about the growth theories have been plentiful and have used differing conceptual and methodological viewpoints (especially interesting is the review of Helpman 2004). These studies have placed

emphasis on different explanatory parameters and have offered various insights to the sources of economic growth. The review of this literature suggests that no single policy or factor leads to productivity growth. Rather, it is a matter of getting a lot of interconnecting things right, and by ensuring incentives are aligned, creating an environment where firms can create and take advantage of opportunities. The main factors that may influence the long-term economic growth are as follows:

1. *Physical capital.* The rate of accumulation of physical capital is one of the main factors determining the level of real output per capita although its effects could be more or less permanent depending on the extent to which technological innovation is embodied in new capital. Investment in physical capital is a key determinant of economic growth identified by both neoclassical and endogenous growth models. However, in the neoclassical model, physical capital has impact on the transitional period, while the endogenous growth models argue for more permanent effects. Whatever the transition mechanism from capital accumulation to growth, the significant differences in the investment rate across countries, and over time, point to it as a possible source of cross-country differences in output per capita.

Physical capital includes factories, tools, computers, machinery, production equipment, and structures such as infrastructure or fixed social capital that are often the result of investments made by the state. These infrastructures range from transport infrastructure (roads, airports, ports, railways), energy, telecommunications, to universities, hospitals, water projects, and other public health measures, e.g., diseases control, etc.

The more capital workers have at their disposal, generally the better they are able to do their jobs, producing more and better quality output. The role of infrastructures is to expand production, to increase resources, and to enhance the productivity of private capital. A good transport system enhances

cohesion and improves access to outlying regions through the reduction of transport costs for both goods and people traveling for leisure or work. Telecommunications are the modern substitute for the connections made through transport and a prerequisite for the development of industries and modern services that rely on the phone, fax, and data transmission systems. An undersized or inadequate infrastructure, such as an electrical network with frequent failures, cuts electricity to homes and businesses is a major obstacle to economic growth in some countries. Without necessary infrastructure, it can be difficult for firms to be competitive in the international markets. The lack of infrastructure is often a factor holding back some developing economies

2. It is not enough that a worker has good equipment; he must also know what to do with it and how to use it in the safest, most effective, and efficient manner. For this reason, *human capital* is the main source of growth in several endogenous growth models as well as one of the key extensions of the neoclassical growth model, because of its role as a facilitator of both technology adoption from abroad (absorption capacity) and the creation of appropriate domestic technology (innovation). It would be impossible to operate the current economy with a population with the literacy levels and formation of a century ago.

The term human capital refers both to the improvement and training of manpower produced by the education and knowledge that is incorporated into the work force and by the learning by doing, as well as to the improvements in their health. A population that is well educated and well trained helps a society to increase its ability and acquire as well as use relevant knowledge (absorption capacity). As knowledge is created by a small number of leader countries in technological terms and most countries do not produce state-of-the-art technology themselves, these latter countries must acquire the technology from elsewhere via trade or foreign direct investment.

Focusing on education, basic education would be important for learning-capacity and utilizing information, while the higher education would be necessary for technological innovation.

In turn, we must bear in mind that in a population with good health, workers can be more productive and learning ability of children to be greater. A longer life expectancy makes it more attractive to invest in human capital and even foreign direct investment, and savings incentive and productivity can be increased. The governments can also play an important role in the accumulation of human capital from the time they can invest in education.

3. Probably the most important factor for productivity growth and therefore economic growth is the *innovation and technological progress*. In practice, most technological improvements are due to deliberate actions, such as research and development (R&D) carried out in research institute or firms.

R&D evolves new ideas and designs and is used by firms in search for blueprints of new varieties of products or higher-quality products. New ideas can also take the form of new technologies, new products, or new corporate structures and ways of working. Expenditure on R&D can be considered as an investment in knowledge that translates into new technologies as well as more efficient ways of using existing resources. Such innovations contribute to the expansion of the so-called frontiers of knowledge, and the accumulation of knowledge will generate growth. Hence, technological change emerges from technical innovations generated by research and development, patenting and software, and productivity enhancing developments in the fields of education management and marketing. And workers today are capable of producing more than in the past, even with the same amount of physical and human capital, because the technology has advanced over time.

The amount of resources that are devoted to R&D can be influenced by government

intervention. In particular, the potential benefits from new ideas may not be fully appropriated by the innovators themselves due to spillover effects, which imply that without policy intervention the private sector would likely engage in less R&D than what could be socially optimal. This can justify some government involvement in R&D, both through direct provision and funding, but also through indirect measures such as tax incentives and protection of intellectual property rights to encourage private-sector R&D.

4. The degree of *openness* of the economy also affects productivity and economic growth. It does through several channels such as exploitation of comparative advantage, technology transfer and diffusion of knowledge, increasing scale economies, and exposure to competition. Trade liberalization promotes competitiveness, efficiency of input, creates incentives to innovate, and ensures that resources are allocated to the most efficient firms. It also forces existing firms to organize work more effectively through imitations of organizational structures and allow to introduce foreign (relatively advanced) technology into domestic production, which in turn has a positive effect on productivity and economic growth. To have a good absorption capacity is a key factor for a good use of the technology transferred. In particular, certain kinds of imports, namely, machinery and equipment relating to foreign R&D, are expected to generate a lot of technology transfer because the technology is often embodied in goods. Moreover, trade liberalization increases investment opportunities and international contacts.
5. *Foreign Direct Investment* can play a crucial role of internationalizing economic activity and can stimulate economic growth by improving technology and productivity. Host economies are expected to benefit from the positive externalities driven by foreign direct investment. Those include knowledge spillovers generated by technology transfers, introduction of new processes, and

managerial skills and know-how diffusion to the domestic market.

6. *Macroeconomic stability-oriented policies* can also have a significant impact on economic growth. A stable macroeconomic environment characterized by low and predictable inflation, sustainable budget deficits, and limited departure of the real exchange rate from its equilibrium level, sends important signals to the private sector about the commitment and credibility of a country's authorities to efficiently manage their economy and increase the opportunity set of profitable investments.

The usual arguments for lower and more stable inflation rates include reduced uncertainty in the economy and enhanced efficiency of the price mechanism. Uncertainty related to higher volatility in inflation could discourage firms from investing in projects that have high returns but also a higher inherent degree of risk. Moreover, large fiscal deficits and high net international debt position make a country vulnerable to global financial shocks and terms of trade shocks (e.g., oil price spikes)

7. *Institutions* also matter for economic growth because they establish the rules of the game in a society or, more formally, they set the humanly devised constraints that shape human interaction (North 1990). Institutions decide how to organize the societies and so determine whether or not the economy prospers. Certain forms societies encourage people to innovate, to take risks, to save for the future, to find better ways of doing things, to learn and educate themselves, solve problems of collective action, and provide public goods, while others do not. Institutions are therefore a key factor for potential economic growth.

Institutions encompass both informal constraints as customs, traditions, codes, or taboos and formal constraints as property rights, legal rules, constitutions, contract enforcement, the political system, and electoral rules. Also encompass public sector imperfections, the degree to which laws and

regulations is fairly applied, the extent of corruption, etc.

Economic institutions are the set of norms relating to production, allocation, and distribution process of goods and services. They can guarantee the rights of intellectual and industrial property so necessary for there to be greater efficiency in the use of resources and also greater technological progress and innovation leading to economic growth. They must also guarantee some degree of equality of opportunity in society, including such things as equality before the law, so that those with good investment opportunities can take advantage of them. Economic institutions also help to stabilize the economy and ensure the proper functioning of the financial system, so it is necessary to have high rates of savings and investment, a good allocation of resources, specialization of the economy, and creating incentives. A well-developed financial system provides funding for capital accumulation, helps the diffusion of new technologies, mobilizes savings by channeling small savings of individuals into profitable large-scale investments, while offering savers a high degree of liquidity.

Economic institutions can also remove or reduce the tariff barriers and the impediments to foreign investment so they may favor a greater exposure to international competition. They may enforce contracts, discourage unfair or abusive business practices, limit the power of rulers, protect individuals both from one another and from the state, increase safety at work, contribute to public health and safety and the development of a more productive and fairer society, set limits on pollution, help protect consumers from potentially hazardous products, ensure that they are able to make informed choices, and influence investments in physical and human capital and technology and the organization of production.

Economic institutions are linked to political institutions because the latter are necessary to the former work. Political institutions

are those that determine the structure of the state and the procedures of the political decision-making process. Political institutions shape the political process that produces legislation and regulation. They also determine the legal system and coordinate the processes that create and enforce the law. Political institutions therefore produce economic institutions and determine their quality. Institutions like democracy and social protection legitimize market outcomes and ensure their endurance. Political institutions can support a market economy by shaping and safeguarding property rights and making the market compatible with social stability and social cohesion. A stable and corruption-free government, a strong independent judiciary, efficient bureaucracy, and political constraint on executive are keys to generate certainty and thus economic growth, since political instability would increase uncertainty, discouraging investment, and eventually hindering economic growth.

8. Certain structural characteristics such as *geographical conditions* are also a powerful driver of economic growth. The country's location, its topography, and access to the sea affect the transport costs and the efficient allocation of resources because where geography is not propitious, the diffusion of technology is more complicated and more costly trade. Thus, it also affects the productivity and competitiveness.

Moreover, the existence of natural resources in abundance is essential for economic growth. The natural resources of a country such as minerals and oil-resources, soil quality, forest wealth, and good climate river system affect the returns to agriculture and its economic structure. A country deficient in natural resources may not be in a position to develop rapidly, although natural resources are a condition for economic growth necessary but not sufficient to one.

9. *Demographic factors* like population growth, population density, migration, and age distribution can play a major role in economic growth.

The population growth can undermine per capita economic growth, and moreover, composition of the population has important implications for growth. A large working-age population is deemed to be conducive to growth, whereas population with many young and elderly dependents is seen as impediment because influences the dependency ratio, investment and saving behavior, and quality of human capital. Population density, in turn, may be positively linked with economic growth as a result of increased specialization, knowledge diffusion, and so on. Migration would affect growth potential of both the sending and receiving countries.

10. Other factors of *sociocultural nature*, e.g., ethnic diversity or cultural diversity may affect growth although in a much more residual, indirect, and unclear manner. For instance, it may have a negative impact on growth due to emergence of social uncertainty or even of social conflicts or a positive effect since it may give rise to a pluralistic environment where cooperation can flourish.

Prohibition

Nicholas A. Snow

Department of Economics, Indiana University, Bloomington, IN, USA

Abstract

A prohibition is a government decree against the production and exchange of a good or service. Recent studies on prohibitions, for a variety of goods and services, such as drugs, alcohol, and prostitution, suggest that prohibitions impose heavy costs and are extremely difficult to enforce.

Prohibition

Governments throughout history have utilized prohibitions on a multitude of goods and services throughout history for a variety of reasons, such as attempts to protect domestic producers from foreign trade, protect consumers, regulate morality, etc. Thus, a prohibition is a means to achieving a broader social end.

In theory, the economics of prohibition is simple. Ultimately, prohibitions are a supply reduction legislation designed to curtail the production, exchange, and consumption of a good through the use of penalties, such as fines, confiscation of assets, and even jail sentences. Prohibitions attempt to reduce supply by making it more difficult for suppliers to produce and distribute the good in question. Within the supply and demand model, this causes a shift of the supply curve up and to the left resulting in a higher price and decrease in quantity demanded.

If enforcement is successful, this results in lower consumption, which has several welfare implications. First, it leads to a loss for consumers resulting from the higher price and the substitution of consumption to lower-valued goods. Second, producers experience a loss from the higher production costs and risks or in a loss of income and utility in needing to shift to other occupations, which differ from their comparative advantage.

Finally, a further utility loss occurs for both consumers and producers because the decrease consumption creates an allocative inefficiency due to the lost gains from trade or what economists call a deadweight loss.

The level of prohibition enforcement is also determined by economic factors. In enforcing prohibitions the government faces scarcity. Thus, enforcement is unlikely to be increased until the goal of eliminating the supply is reached. Just as individuals must equate marginal costs with marginal benefits in decision-making, so too must policy makers. Enforcement is not costless and requires the use of resources. Every dollar spent on prohibition enforcement is a dollar not spent on some other policy or a dollar not spent on something else by the taxpayer. Thus, the law of diminishing marginal utility exists in the policy world as well as for the individual. Policy makers must find the optimal level of enforcement, which is unlikely to lead to zero consumption. Enforcement will lower consumption but whether or not this leads to a level of consumption that achieves the policy goal is determined by the opportunity costs perceived by the individuals who make up society.

From a policy perspective, the success of the prohibition should not stem from the evidence of reduced consumption but rather whether the reduced consumption leads to the desired outcomes or not. A further difficulty in regard to the enforcement of a prohibition is the dynamic effects, or the unintended consequences, of the law. First, in pushing the trade underground information is greatly restricted due to the necessary premium on secrecy, which in turn greatly reduces price competition. This leads many in the market to charge monopoly prices, which widens profit margins. These large profits create an incentive for many, normally quite law abiding, individuals to break the law. This will include not only those directly participating in the trade but also government officials who succumb to the temptation of corruption. This has an effect of increasing both supply and demand, which attracts the attention of government officials, who then attempts to crack down. As a result the amateur is pushed out of the market but with the continued profit opportunities

for individuals who are skilled at evading the law remain.

Second, enforcement can also lead to consequences concerning the good itself, such as a lower quality. With fewer competitors, suppliers do not need to rely on quality as much as they would in a legal market. The principle consequence, however, is what Richard Cowan, in a 1986 article, called the “iron law of prohibition,” which is “the more intense the law enforcement, the more potent the drugs become.” Cowan’s point was related to drug prohibition but the principle stands for other goods as well. There are two reasons for this. First, the prohibition makes smuggling a necessary activity in order to get the goods to the consumers, and smugglers will prefer to minimize the bulk of their goods. For example, typically a shot of liquor, glass of beer, and a glass of wine have roughly the same amount of alcohol. Thus, due to its smaller size, liquor becomes more profitable to smuggle, driving beer and wine out of the market. Second, from the demand side, the same considerations apply. Liquor is more potent than beer and wine; it takes less of the good to do the job, of getting drunk in this example, for the consumer. When taking a hip flask with you for a night on the town filling it with whiskey is more effective than filling it with your favorite Pinot Noir.

These unintended consequences of prohibition are a causal result of the relationship between the market process and the intervention into that process. While these consequences are not completely predictable in detail, they are not completely surprising either. Interventions into the market’s discovery process alter that discovery process; it does not eliminate it. Economist Israel Kirzner categorizes the four different ways interventions can broadly alter the market’s discovery process, namely, by creating an undiscovered discovery process, an unsimulated discovery process, a stifled discovery process, and a wholly superfluous discovery process. All four of these are important for an intervention like a prohibition.

The undiscovered discovery process refers to the demand for government intervention due to either, or both, an ignorance or impatience with the market’s ability to achieve the desired end or

state of affairs. The market is a process not an instantaneous state of affairs. Further markets operate under imperfect knowledge. Thus, corrections take time and occur under a decentralized spontaneous process. Prohibitions are often implemented due to perceived market failures, but often these failures are a result of other government interventions that impaired the market process in the first place. In other words, the undiscovered discovery process matters because government interventions are further demanded because imperfections of interventions are not seen or are blamed on the market and/or individuals are ignorant and/or impatient with the markets progress toward a solution.

The unsimulated discovery process refers to the inability of the bureaucracies in charge of a regulation to simulate the market's discovery process. Prohibition enforcement is made difficult because the bureaucracies in charge of enforcement are unable to simulate the discovery, or success, of the market. Bureaucrats have little incentive to innovate in order to improve efficiency within their tasks because they lack the incentive structure created by a competitive environment. As a result enforcement tends to be inefficient relative to what the market could or would produce. And this obviously creates a difficult hurdle for enforcement.

Interventions into the market also help to stifle the market's discovery process. Innovations in new techniques, safety, product characteristics, sources of supply, etc. created through this process are no longer discovered. In the case of prohibitions, the discovery process can be completely destroyed and also curtail and distort the process for other goods, as innovations in one area may have implications in others. And understanding the magnitude of this is simply not possible.

Finally, the wholly superfluous discovery process is the creation of new economic profit opportunities in response to the government's intervention. These new discoveries in search of profits are not always desirable. The new discovery process often creates wholly unexpected and undesired outcomes that create tremendous change in terms of both the product and the supply chain. Essentially, the government's attempts at

enforcement are undercut as entrepreneurs figure ways to supply the good to consumers, and the means they use may even be worse than what the regulation is trying to fix. As economist Milton Friedman, in his 1975 book *An Economist's Protest*, put it, "There is ample evidence that imagination and innovation are not stilled by restrictive legislation – only diverted to figuring ways around it."

The altered profit opportunities not only affect market participants but also government officials responsible for enforcing the prohibition. Since the bureaucrats are not the residual claimant of the bureaucracy they are a part of, black markets provide chances to gain by providing market participants either protection or selective enforcement. In other words, a problem of graft and corruption within their own ranks will further impede the government's efforts to enforce the law, and this is a direct result of the wholly superfluous discovery process.

While not all prohibitions will be the same, the economic theory of prohibition does tend to illustrate difficulties with the enforcement of restricting market activities for many goods and services.

Abstract

The term promotional effort refers to all strategies aimed at broadening a firm's market scope through the establishment of a larger and more loyal consumer basis. Advertising, public relations, sales promotion, personal selling as well as price-related strategies affecting a firm's sales potential are addressed. Both positive and normative approaches are briefly reviewed, discussing the theoretical and empirical issues studied in the existing literature.

Synonyms

Product promotion strategy; Promotional activities

Definition

The term is used to refer to the qualitative and quantitative aspects of a firm's strategies aimed at broadening its market scope through the establishment of a larger and more loyal consumer basis. According to Kotler et al. (2013), such activities can generally be classified into product management, pricing, promotion, and distribution. Promotional activities include advertising, public relations, sales promotion, personal selling as

well as database marketing, direct response marketing, sponsoring, social media, and other alternative marketing activities (Clow and Baack 2014). In formal economic models, promotional effort is treated separately from pricing, in which case it refers to investments enhancing a firm's potential market before pricing is taken into account. However, price-related strategies like price announcements, bundle pricing, or low price guarantees could be considered as part of a firm's promotional effort, rather than merely a pricing decision.

Impact Measurement and Responses to Promotional Effort

The measurement of a firm's promotional effort is a challenge for marketers. First, a problem arises due to the difficulty in identifying the costs specific to different activities (e.g., Chapman 1986). Second, a problem arises with the measurement of a direct causal relationship between a given promotional strategy and its outcome (Berger et al. 1964), like, for example, consumers' reactions such as their attitude toward the brand or the sales rate of products. Third, this relationship is moderated and/or mediated by unknown and uncontrolled factors (Kuehn 1964; Berger et al. 1964). Fourth, the outcome of promotional effort is delayed, which causes the problem of accountability over time between promotional effort and outcomes (e.g., Mills 1959; Miller and Strain 1970). Finally, multiple promotional activities of a firm may support or weaken each other.

Similar problems arise with respect to various products of a multiproduct firm. To overcome the complexity of the resulting setup, several experimental studies have been performed in order to isolate promotional effort effects within each separate domain (e.g., Berger et al. 1964; Miller and Strain 1970). To find the optimum promotional effort of a firm, economic models have taken into account the multiperiod, multicompetitor, and multiproduct nature of the problem (e.g., Gupta and Krishnan 1967a, b). Furthermore, the price of the firm's product(s) (e.g., Carpenter 1987; Krishnan and Gupta 1967) as well as a firm's price changes (price reductions or price

promotions) have been analyzed more in detail, including consumer switching or variety-seeking behavior (Kahn and Raju 1991). In order to be effective and efficient with respect to its promotional activities, a firm needs to: (1) *choose* the *right* promotional activities, to which its target group pays attention and responds positively. In addition to this, the selected promotional activities must fit to the firm's positioning and image and differentiate the firm from competitor; (2) *execute* the selected promotional activities in an efficient and effective way; and (3) *integrate* all promotional activities to one "main picture" in order to create a unique brand image in the consumer's mind.

Qualitative and Quantitative Aspects of Promotional Effort

From a managerial point of view, qualitative and quantitative considerations define the two major domains along which promotional effort enters into a firm's decision-making process. Qualitative considerations regard the choice of the actual strategy mix and the nature of explicit or implicit messages and signals transmitted to the consumer, whereas quantitative considerations regard the firm's investment in the different promotional activities. Along the qualitative domain, a firm's promotional effort could aim at creating or reinforcing the consumer's or stakeholder's brand awareness, stimulating their interest in the firm's products, encouraging first or more frequent purchases of the firm's products and building a long-term relationship (Bester and Petrakis 1996; Moraga-Gonzalez and Petrakis 1999) between the firm and its customers (Clow and Baack 2014; Keller 2013). The marketing literature emphasizes the need for an integrated strategy in order for promotional effort to lead to a unified image of the firm and its brands in the consumer's mind (Keller 1993, 2013), so that all promotional activities should support each other, transferring the same meaning to the receiver (Clow and Baack 2014). The importance of these qualitative aspects of promotional effort in a firm's decision-making problem has contributed to the fact that the issue has attracted researchers from many different

disciplines, like economics, management, psychology, sociology, neuroscience, media and communication science, and even sociolinguistics.

Thus, the use of promotion techniques is informed by all the aforementioned approaches, pointing clearly to a possibility and desire of firms to intervene and affect the consumer's decision-making context and overall attitude, beyond pure product-related information, so that along all touch-points between customer and brand, the firm needs to communicate the same information to create a strong brand image in the customer's mind and to reinforce customer's brand knowledge (Keller 2013; Rossiter and Bellman 2005). Despite that, mainstream approaches within both the economics and marketing disciplines have strongly insisted on the information-enhancing role of advertising and promotional effort in general, adopting a preference invariance approach, similar to what could be motivated by Stigler and Becker's (1977) *De gustibus non est disputandum* (see also Becker 1996; Becker and Murphy 1993). As a consequence, all relevant legislations are almost exclusively concerned with the truthfulness of messages contained in informational campaigns, rather than with the persuasive effects of advertising, aimed at the subconscious processes underlying the consumer's choices (except for a clear ban of advertising aimed at trapping children's preferences).

Regarding the channel through which promotional effort broadens a firm's market potential, promotional effort may target retailers and wholesalers or end consumers. In the former case, the firm uses a *push* strategy, offering incentives directly to retailers and wholesalers (e.g., through personal selling or promotion). The aim is that retailers and wholesalers are the ones who engage in specific marketing activities such as personal selling, sales promotion, or advertising directly to the end consumers (Kotler et al. 2013; Barreda and Georgantzis 2002). In the latter case, the firm uses a *pull* strategy, promoting its brands and products directly to end consumers, for example, through TV spots, print advertisements, mobile marketing, and mailings.

Finally, the quantitative approach to promotional effort focuses on the issue of advertising expenditure and its efficiency as a market-

enhancing mechanism. Both types of advertising, informative (Grossman and Shapiro 1984) and persuasive (Bloch and Manceau 1999; von der Fehr and Stevik 1998) have been studied in oligopolistic contexts to reach a rather robust conclusion that advertising expenditures may be excessive from a social point of view and may lead firms to a prisoner dilemma-type of situation in which firms are trapped into “run-to-stay-still” competition. In such a case, firms may also end up earning lower profits than they would in a world without advertising. In the case of persuasive advertising, enhancing consumer heterogeneity seems to be the desired effect of promotional effort due to its competition-reducing ability. Generally speaking, this can be in detriment of social welfare even in the extreme case in which heterogeneity per se is in favor of a prosocial or environmental-friendly consumer behavior (Garcia-Gallego and Georgantzis 2009). Most of this wisdom has not been translated sufficiently into specific measures of economic policy and is largely neglected by the existing laws, except for some regulation regarding limitations of the overall time and space that advertising should be allowed in certain media.

Within the scope of informative advertising, special attention has been paid recently to best-price guarantees (e.g., *if you could find it cheaper, we refund the difference*) advertised by many large retailers all over the world. While, at a first glance, such a strategy appears to be a signal of the firm’s commitment to prices which are lower than any of its rivals, suspicion has been raised by some authors (Arbatskaya et al. 2004, 2006), arguing that price guarantees may be used by firms wishing to facilitate cartel sustainability and discourage price cuts, because the transparency achieved regarding rival prices makes deviations from collusive agreed prices easier to detect. Both the promotional and the cartel facilitating explanations of price guarantees have received some support. The controversy persists, calling for a case-by-case treatment (Fatas et al. 2013) when concerns arise regarding the true motivation and effects of such guarantees. Other subtle forms of informative advertising relate to signaling of the firm’s attitude toward certain quality aspects of their products, like

safety (ISO standards), chemical composition, fair trade rule compliance, and environmental performance achieved by certificates and labeling (Loureiro and Lotade 2005). In those cases, legislation is assisted by the certifying or label-awarding authority so that no issues arise regarding imperfect and asymmetric information.

Property Rights: Limits and Enhancements

Geoffrey M. Hodgson
Hertfordshire Business School, University of
Hertfordshire, Hatfield, Hertfordshire, UK

Definition

This essay considers the concept of “property right” as typically employed in “the economics of property rights.” Some early uses of the term

“property right” in economics are quoted before moving to the predominant usages in the standard “economics of property rights” today. This prevailing usage is compared with the more nuanced notion of “property right” in legal theory. It is argued that, for the purposes of understanding the role and impact of property rights on economic performance, it would be better for economists to return to the legal meaning of property rights. This legal meaning can cope better with important developmental phenomena such as the use of property as collateral to finance loans. Also the recognition of the legal character of property opens doors for a richer understanding of motivations to respect property rights, which is consistent with empirical data indicating that people are not simply motivated to respect laws out of instrumental calculations of costs and benefits.

Introduction

Nowadays, many economists concur that the development of secure and enforceable property rights is a vital factor in the process of modern economic development. But what are property rights? Different answers to this question focus on different kinds of social relationship or institution, which, in turn, can lead to different policy recommendations. On closer inspection, there are major differences of opinion on this issue.

These differences can be divulged by posing two connected queries. First, are property rights conceived as an eternal feature of the human condition, or are they historically specific, emerging (say) with states and legal systems? Many researchers in this field treat property as an evolved – spontaneously or endogenously emerging – response to human interactions over territory or other wealth, and do not assume that states or legal systems are necessary for its emergence.

The division of opinion on the first query often related to the divide in the history of economics between those that emphasise universal principles or laws, and those that claim that concepts such as exchange, supply, demand, and even calculative rationality are historically specific, depending on particular economic institutions. Much of modern

This chapter distils and extends some material from Hodgson (2015a, b).

economic theory emphasizes universal principles, whereas others, including the German historical school and the original American institutionalists, emphasized historical specificity.

The second, related, query is whether “property” is treated as synonymous with mere possession – i.e., *de facto* control – over a resource, or does it involve the acquisition of declared rights, backed up by institutions of legislation, adjudication, and enforcement? Again the rival choice of emphasis on universality or historical specificity is relevant here. Those that seek a universal concept of property must find it also in worlds where there is no state, where custom rules without institutionalized law. By contrast, those that make property more than possession and relate rights to legal institutions are obliged to abandon the notion that property is a universal or ahistorical concept.

This entry argues that this fundamental difference of outlook over the nature of property has major theoretical and practical consequences. It has divided opinion since the disciplines of law and economics began to interact in the nineteenth century. It has yet to be played out to an adequate solution.

Consider some examples. John R. Commons was an early institutional economist and a leading explorer of the overlapping territories of economics and law. He was clear: “in the end, the actual title to property rests on the sovereign power of the state to enforce its decrees. . . . There is, strictly speaking, no such thing as absolute, unlimited right of property, which law steps in as an afterthought to restrict” (Commons 1893, p. 110).

The institutional economist Thorstein Veblen also pointed out that property is historically specific: “no concept of ownership, either communal or individual, applies in the primitive community. The idea of communal ownership is of a relatively later growth” (Veblen 1898, p. 358).

A historically specific, state-related concept of property also pervades much analysis by legal scholars. For example, the leading legal theorist Antony Honoré (1961, pp. 107, 115) insisted that property is much more than possession or control:

A people to whom ownership was unknown, or who accorded it a minor place in their arrangements, who meant by *meum* and *tuum* no more than

“what I (or you) presently hold” would live in a world that is not our world. . . . To have worked out the notion of ‘having a right to’ as distinct from merely “having” . . . was a major intellectual achievement.

Legal scholars Daniel Cole and Peter Grossman (2002) have documented how the notion of “property rights” in prevailing contemporary approaches in economics departs radically from that notion in law. For other insights and dissenting voices on the treatment of property, see Hernando (2000), Steiger (2008), Fukuyama (2011, pp. 66–71), Arruñada (2012, 2017), and Heinsohn and Steiger (2013).

This entry explores this crucial divergence of usage and interpretation of a key concept. The following section lays out the concept of property in much of “the economics of property rights.” Sections “[Why Do People Obey the Law?](#)” and “[Property Rights and Economic Development](#)” explore some implications of the discussion in terms of practical analyses of the roles of property. Section “[Concluding Remarks](#)” concludes the chapter.

The Concept of Property in the Contemporary “Economics of Property Rights”

At least in its early stages of its development, the now-conventional “economics of property rights” was influenced by the treatment of institutions in the Austrian school of economics, particular by Carl Menger, Ludwig Mises, and Friedrich Hayek.

Menger famously located the essence of some institutions in the spontaneous arrangements that engender or sustain them, rather than in acts of decree by a state or other public authority. Similarly, the standard economics of property rights strives to understand property as a spontaneous institution, which does not necessarily involve the state.

Mises made a sustained attempt to make core economic concepts as universal as possible. So when he considered the nature of ownership, he treated the legal aspect as merely a normative

(“ought to have”) justification of de facto “having” something:

From the sociological and economic point of view, ownership is the *having* of the goods . . . This *having* may be called the natural or original ownership, as it is purely a physical relationship of man to the goods, independent of social relations between men or of a legal order. . . . Economically . . . the natural *having* alone is relevant, and the economic significance of the legal *should have* lies only in the support it lends to the acquisition, the maintenance, and the regaining of the natural *having*. (Mises [1932] 1981, p. 27)

Hence, for Mises, ownership was natural and ahistorical rather than legal or institutional. An individual-physical rather than a social relationship, it was deemed independent of law or any other social institution. He downgraded the institutions required for the legitimation, protection, and enforcement of the capacity to have, and neglected social aspects of ownership that may signal power or status.

Hayek’s position was in some respects different from Mises, but by arguing that all law was basically custom, Hayek (1973, pp. 72–5) echoed Mises’s argument by removing any historical specificity to the notion of law. In part, this is a matter of the definition of law. But there are good reasons for regarding law as a characteristic of systems with a fully institutionalized judiciary and legislature (Hodgson 2015a, b). Hayek not only reduced law to custom, but he treated common law as essentially spontaneous and customary, whereas in fact it was by large part codified and made consistent by the state (Fukuyama 2011, pp. 254–60).

It is possible to reject Hayek’s extremely wide characterization of law without adopting the view that law emanates simply from the state, and without underestimating the crucial role of custom in legal development. Indeed, all law depends to a large degree on custom, for its origin or for its implementation. While law, in the narrower and historically specific definition, implies the state, it is not constituted simply by decree and it depends upon custom.

Notably, in contrast to Hayek, Ronald Coase never suggested that property in a modern market economy could exist or be understood without a state legal system. Coase (1988, p. 10) wrote:

When the physical facilities are scattered and owned by a vast number of people with very different interests . . . the establishment and administration of a private legal system would be very difficult. Those operating in these markets have to depend, therefore, on the legal system of the State.

Subsequent writers on “the economics of property rights” departed from this maxim, enabling them to tackle the definition of “property right” in a very general way, ignoring its dependence on “the legal system of the state.”

Armen Alchian was a key figure in the development of the contemporary “economics of property rights.” Alchian (1965) defined private property rights in terms of assignments of the ability to choose the use of goods (without affecting the property of other persons). Following Mises, his definition was largely in terms of de facto powers of control rather than legal or moral rights.

Alchian removed morality from the notion of a “right.” He downgraded the role of law, from being the source of legitimate authority concerning rights to one means among others for enforcing possession and control. But typically, we refer to moral or legal rights, we do not simply mean de facto ability to control resources. The *Oxford English Dictionary* defines “right” (as a noun) as “that which is morally correct, just, or honourable” or “a moral or legal entitlement to have or do something.” It means much more than the ability to do something.

Later Alchian (1977, p. 238) defined the “property rights” of a person in universal and institution-free terms including “the probability that his decision about demarcated uses of the resource will determine the use.” Alchian’s definitions of property neglect the essential concept of legitimated, rightful ownership. This concept is important, even if what is rightful is contestable or difficult to identify. His definitions denote possession rather than property.

Similarly, the highly influential property-rights economist Yoram Barzel (1994, p. 394) defined property as:

an individual’s net valuation, in expected terms, of the ability to directly consume the services of the asset, or to consume it indirectly through exchange.

A key word is *ability*: the definition is concerned not with what people are legally entitled to do but with what they believe they can do.

This explicitly removed the question of legal title from the definition of property. The upshot of this is that if a thief manages to keep stolen goods then he acquires a substantial property right in them, even if, on the contrary, legal or moral considerations would suggest that they remain the rightful property of their original owner. Elsewhere Barzel (1997, p. 3) argued:

The term 'property rights' carries two distinct meanings in the economic literature. One ... is essentially the ability to enjoy a piece of property. The other, much more prevalent and much older, is essentially what the state assigns to a person. I designate the first 'economic property rights' and the second 'legal (property) rights.' Economic rights are the end (that is, what people ultimately seek), whereas legal rights are the means to achieve the end. Legal rights play a primarily supporting role...

Barzel's distinction between "economic property rights" and "legal property rights" has proved influential in this genre of literature. Barzel made it clear that his version of "the economics of property rights" is not about legalities. But it is questionable to regard "the ability to enjoy" something as a "right." Enjoyment can exist without rights, and rights without enjoyment. Rights result from institutionalized rules involving assignments of potential benefit. They always involve relations between people as well as relations with things. The "ability to enjoy" may not involve more than an individual's relationship with an object.

One possible response is that all this is essentially about the choice of definitions and the uses of words. In particular, property rights economists might simply say that what some call "possession" they call "economic property rights" and what some call "property rights" they call "legal property rights." Consequently, we can go through and edit the relevant economics of property rights literature, making the appropriate terminological substitutions, and everything else would remain valid.

This is contestable. Words carry meanings that we cannot simply alter at will. While the foundational economics of property rights

literature brings important and valid insights, it would still be impaired after these terminological substitutions. First, using the word "right" to describe something that is not a right but a matter of de facto control is misleading: it obscures the adopted legal meaning of rights in modern legal and economic systems (Cole and Grossman 2002).

Second, attention is diverted from the roles of moral sentiments and dispositions to obey authority: they are important parts of human motivation, alongside greed and self-interest. Third, even with the terminological substitutions, the foundational property rights literature would have an inadequate treatment of (legal) property rights as collateral to obtain loans, and of the historically specific legal institutions that make collateralization possible. These issues are explored in the following two sections.

Why Do People Obey the Law?

Consider the intrinsic role of law in human motivation. Intrinsic motivation stems from the perceived nature of law itself, rather than from the sanctions or rewards of the legal system. The "economics of property rights" often neglects this intrinsic motivation: it is often assumed that law impinges on behaviour principally as a cost or constraint. Obeying the law is simply a matter of expected costs and expected benefits, where no benefit is assumed from legal compliance itself.

Hence, having made his distinction between two kinds of "rights," Barzel (2002, pp. 16, 157) claimed that: "What individuals maximize (subject to their personal safety) is the value of their *economic rights*." These exclude "legal rights," which are defined as "*claims over assets delineated by the state*." In other words, individuals are *ceteris paribus* indifferent to "legal rights" and act solely to maximize their enjoyment of assets under their control, whether these assets are obtained legally or illegally. This assumes a particular form of maximizing behaviour where law itself has no direct input as an argument in the preference function.

Barzel accepted that the law may matter. It may be a major factor in determining outcomes in terms of control and enjoyment of resources. But Barzel (1997, p. 3) argued that law matters only insofar as it leads to “what people ultimately seek,” namely the enjoyment of resources. Legal obedience has no intrinsic value, and it is simply treated as an instrumental “means” to that “end.” Legal obedience would not appear as an argument in any presumed preference function. Law is regarded as simply an instrumental means to an end. According to Barzel, obeying the law is not an end in itself.

By contrast, the subfield of psychological jurisprudence has gathered considerable survey data to establish that people place some normative value on obeying the law, in addition to any instrumental consideration of expected personal costs or benefits. Tom R. Tyler is the leading authority in this area. Tyler (1990, p. 3) contrasted the “instrumental perspective” where “people are viewed as shaping their behaviour to respond to changes in the tangible, immediate incentives and penalties associated with following the law” with the “normative perspective” concerned with “what people regard as just and moral as opposed to what is in their self-interest.”

Supported by evidence gained from a survey of several hundred citizens in Chicago, Tyler (1990) argued that citizen may be inclined to obey the law for noninstrumental as well as instrumental reasons. For some actors, the estimated costs (involving estimates of the chances of being caught and likely punishments) and benefits of breaking the law are weighed against the costs and benefits of compliance. But the evidence of Tyler and others suggests that such instrumental calculations have relatively little effect on compliance. More important is internalized obligation, stemming from other considerations.

First, citizens often comply with the law because they regard the legal authority as having a legitimate right to lay down rules that people must obey. The notion of legitimate authority can have several possible bases, but in modern democracies, it mainly derives from the belief that the popular election of a government makes such state authority legitimate. Max Weber ([1922]

1968, p. 215) saw legal authority and legitimation as “resting on a belief in the legality of enacted rules and the right of those elevated to authority under such rules to issue commands.”

Second, citizens sometimes comply with a particular law because it is believed to be moral. This is particularly the case with laws against murder or rape, but may not be so with other laws, such as those governing traffic on roads. Tyler argued that moral beliefs sometimes help to sustain laws. But this does not work when people believe that a particular law lacks sufficient moral force.

Instrumentalists in general, and proponents of utility-maximization in particular, argue that the issues of legitimacy and morality can be incorporated in the calculus of costs, benefits or utility. Hence advocates of utility-maximization claim that when someone acts according to their perceptions of legitimacy or morality, they gain extra utility from a “warm glow” of self-satisfaction. A problem with this argument is that it undermines the very meaning of legitimacy and morality. The whole point of actions in accord with perceived legitimacy or morality is that they do not necessarily serve self-interest. Acting morally means “doing the right thing,” even if it is costly to the actor. People obey legitimate legal authority saying “because it’s the law.” These deontic motivations cannot be reduced to convenience, convention, or cost-benefit calculation, in accord with a unidimensional calculus of utility or desire.

Both adults and children feel strong obligations to obey the law. Austin Sarat (1975) found that 70% of adults in his US sample agreed that a law “must always be obeyed.” A survey of US high school students found that 77% of whites and 72% of blacks agreed that “people should always obey the law” (Rodgers and Lewis 1974). Tyler (1990, p. 178) summarized a major implication of his survey of Chicago citizens:

People obey the law because they believe that it is proper to do so, they react to their experiences by evaluating their justice or injustice, and in evaluating the justice of their experiences they consider factors unrelated to outcome, such as whether they have had a chance to state their case and been treated with dignity and respect. . . . The image of the person resulting from these findings is one of a person whose attitudes and behavior are influenced

to an important degree by social values about what is right and proper. This image differs strikingly from that of the self-interest models which dominate current thinking. . .

Our ingrained inclinations to respect those in authority were dramatized by the experiments of Stanley Milgram (1974), who invited members of the public to help in a laboratory study ostensibly about learning. A “scientist” asked these recruits to administer electric shocks to a subject, to punish wrong answers to questions. Milgram found that a majority of adults would administer shocks that were apparently painful, dangerous, or even fatal, if ordered to do so by the person in authority. In fact, there were no shocks and the subject was an actor, feigning agony or even death. This experiment shows that people can willingly accept the orders of perceived authority figures, even when their own moral feelings are violated.

Milgram (1974, pp. 124–5, 131) argued that our dispositions to respect authority emanate from the evolutionary survival advantages of cohesive social groups. While socialization and learning are clearly important in developing propensities to obey authority and the law (Engel 2008), Milgram also proposed that the human species has evolved an inherited, instinctive, propensity for obedience that is triggered by specific social circumstances. He suggested that dispositions to respect authority have both genetic and cultural foundations. This is in accord with Charles Darwin in his *Descent of Man*, who proposed that human tribes that developed systems of social obedience and cooperation, and a moral code to buttress these attributes, would survive in competition with other human tribes and in dealing with their environment.

These arguments undermine the view of Barzel and others that respect for the law – based on its perceived legitimacy or moral concordance – plays little or no part in attitudes toward property or other legal rights. The insistence that property is a legal right does not imply that people never break the law, or that law alone somehow predicts behavior. But the establishment of legal rights, through perceptions of moral legitimacy and the use of state power, can affect intentions or behavior. As Honoré (1961, pp. 107, 115) insisted, an

economy involving mere possession is very different in nature and outcomes from one that has institutionalized rights of property.

The mistaken removal of legal rights from the definition of property cannot be justified on the ground that they are unnecessary to explain or predict behaviour. Any explanation of dispositions, choices, or preferences must take such factors into account. If economists are interested in predicting behavior on the basis of some scientific understanding of what causes it, then they must take matters of motivation, including the instrumental and the normative into account (Merrill and Smith 2007).

Property Rights and Economic Development

Arguments emphasizing the perceived legitimacy of the legal system have implications for establishing the rule of (state) law, and particularly installing just and secure property rights to help promote economic development.

China is an important test case for these arguments. China began its market reforms in 1978 and its systems of property, commercial, and corporate law are still relatively underdeveloped compared to Europe or North America. This fact, alongside its highly impressive economic growth since 1978, has led some economists to conclude that legally-enforced property rights are of lesser significance.

But, despite superficial appearances to the contrary, there is evidence that legal systems and legal property rights matter. China’s explosive growth started when land-use (*usus fructus*) rights were widely conceded to the peasants after 1978 (Coase and Wang 2012). Relevant legislation concerning land leasing followed rather than preceded this concession. But this does not mean that legal land-use rights were unimportant. Local power from below tentatively established *de facto* powers, which spread widely and became *de jure* when it was legally ratified by the state. This endorsement, along with the institutional arrangements established from below, was vital to safeguard these rights.

Legalities matter and evidence suggests that they matter still more as capitalism develops. Further economic development in East Asia may depend in part on the installation of superior state legal and political systems governing and protecting property and contracts. Private ordering is vital but insufficient. The cross-country evidence of Robert J. Barro (1997) and others suggests that economic growth is correlated with the rule of law, among other factors.

By contrast, the Alchian-Barzel approach might see it as sufficient that Chinese entrepreneurs can control resources sufficiently to enable prosperity and rapid growth. Matters of legal infrastructure and enforcement would be secondary. Instead, the alternative perspective outlined here would point to the priority of developing legal institutions, their separation from political authority, and the related reform of the political system.

As Hernando (2000) and others have pointed out, the registration and enforcement of property rights (particularly in land and buildings) is a necessary condition for economic development. But Arruñada (2017) argued persuasively that property registries, while necessary, are insufficient. Among other things, they need to be backed up by well-functioning systems of law enforcement.

The exclusive focus on control in “the economics of property rights” overlooks the use of property as collateral for loans. The possibility of collateralization – which relies on legal and financial institutions – cannot be based on possession alone. It involves institutions: relations between individuals as well as relations between individuals and things. While emphasizing the importance of “property rights,” much of this discourse side-lines the vital institutions that are required to sustain them and make them fully operational in a developed economy.

Another relevant historical case study is the English Glorious Revolution of 1688. Douglass North and Barry Weingast (1989) famously claimed that this event made property rights more secure by constraining the power of the monarch. But on closer inspection, it becomes clear that property rights in England were

relatively secure centuries before 1688 (Fukuyama 2011, pp. 418–20). The problem instead was that these rights involved *entails*, which kept land and buildings in the family and prevented their use as collateral to secure loans.

Instead of making property rights secure, 1688 led to new alliances and a series of wars, requiring the state to reform its administration, gather more taxes, and help create a new financial system. This created conditions in the eighteenth century that eventually incentivized and facilitated the use of land as collateral for loans for agricultural, infrastructural, and industrial development (Hodgson 2017). The overly simplistic treatment of property rights as mere possession obscures the importance of different aspects of property (Honoré 1961) and the crucial role of potential collateralization in creating the conditions for the Industrial Revolution.

Attempts to make “property rights” analysis universal, so that it applies to societies without effective (state) legal authority draw our attention away from the importance of property rights, properly defined (Arruñada 2017). Of course it is important to understand extra-legal enforcement mechanisms, such as with pirates and mafias, but we should not pretend that might and right are the same. Of course, studies of worlds without (state) legal enforcement can help us devise policies that apply to developing countries where the state is weak or dysfunctional. But – following Coase (1988) among others – we should not assume that such spontaneous mechanisms are sufficient, or can apply to large-scale, complex economies. The reinstatement of a more genuine concept of “property rights” in development economics would lead to greater emphasis on the importance of an effective legal system that enjoys some autonomy from political or sectional power with some perceived justice in its proceedings.

Concluding Remarks

The success of capitalism has depended on systems of law enforcement. But these took a long time to establish. Even today, in much of the world, systems of law enforcement are weak,

expensive, corrupt, or inaccessible. In their absence, people fall back on other means of establishing obligations and ensuring compliance. Commerce then works through clan or family ties, shared religion, or ethnicity, bureaucratic cooption and corruption, or threats of violence to person or property. Systems of spontaneous enforcement show how commercial agreements can be maintained in the absence of adequate state systems of law. Such systems existed in history and persist today in some contexts. Hence they are important objects of analysis. But this should not mislead us into believing that fully-developed modern capitalist systems can rest on purely spontaneous or customary foundations.

A crucial argument here is that legal institutions have to be taken into account in “economic” analysis. Law is much more than a constraint: it matters too for an adequate understanding of human motivation and the financial dynamics of capitalism. An alternative approach – which takes the impact of legal institutions more seriously – is described as *legal institutionalism* (Hodgson 2015a).

An appreciation of noninstrumental motivations for legal compliance, which are part and parcel of the arguments here concerning the nature of property rights, challenges the use of utility-maximization as sufficient model of human behaviour. If “economics” is confined to utility-maximizing agents, then “economics” cannot adequately deal with the reality of property rights. But if economics takes on board the insights of Adam Smith, Ronald Coase, Amartya Sen, and several others, who all adopted more complex views of human motivation involving moral sentiments, then the “economics of property rights” can be greatly enriched.

Proportionality Test

Tomáš Sobek¹ and Josef Montag²

¹Faculty of Law, Masaryk University, Brno, Czech Republic

²International School of Economics, Kazakh-British Technical University, Almaty, Kazakhstan

Abstract

Proportionality test is a legal method used by courts, typically constitutional courts, to decide hard cases, which are cases where two

or more legitimate rights collide. In such cases a decision necessarily leads to one right prevailing at the expense of another. In order to decide such cases correctly, the court must balance the satisfaction of some rights and the damage to other rights resulting from a judgment. This entry overviews the proportionality test and the four steps of implementing the test. We also discuss the incommensurability problem, which is the main criticism of the balancing approach.

Proportionality Approach to Hard Cases

Courts, constitutional courts, in particular, sometimes face cases that cannot be decided by referring to the letter of the law or an interpretation thereof. Such cases, henceforth “hard cases,” are characterized by a collision of legitimate rights, or public interests, that are protected by the law, typically by the constitution. Adjudicating such hard cases inevitably results in a decision as to which right will prevail at the expense of limiting the other right. That is to say, in such cases courts face a trade-off situation.

In order to decide such cases in a rational manner, the adjudicators need a criterion to distinguish good and bad trade-offs. After the Second World War, the German constitutional theory developed the proportionality test as its main methodological tool for reconciling conflicting rights and values. Proportionality test is a method that allows courts to structure the decision dilemma at hand in a way that facilitates the decision to be carried out in a rational and transparent manner by balancing the benefits and costs – broadly understood – of alternative courses of action. And this approach proved to be viable. The proportionality test, indeed, became a dominant technique of adjudication of hard cases around the world (Aleinikoff 1987).

Proportionality test can be viewed as a set of rules for determining the necessary and sufficient conditions for a limitation of a constitutionally protected right and ascertaining whether these conditions are satisfied. The proportionality test consists of four steps or sub-tests (Alexy 2014).

A limitation of a constitutional right by a legal act is constitutionally permissible if and only if (i) the act pursues a legitimate aim (legitimacy test), (ii) the act is capable of achieving this aim (suitability test), (iii) the act impairs the affected right as little as possible (necessity test), and (iv) the importance of achieving the aim outweighs the importance of preventing the limitation on the affected right (balancing test or proportionality *stricto sensu*).

If these conditions are satisfied, the test concludes that the right under consideration has greater weight and should prevail over the conflicting right. The resulting preference relation, however, is specific to the case at hand only and its context. The outweighed right is not to be considered invalid; it may itself outweigh some other right in different circumstances.

From the economic point of view, the proportionality framework is interesting because it embodies the requirement for efficiency. The rules of proportionality require that the tradeoffs that courts make are efficient in the sense that the prevailing right is of higher social value and that its protection is achieved with minimal costs for the “losing” right. The test postulates that there should be a reasonable relationship between a particular purpose to be achieved by law and the legal means used to achieve that purpose. Judges must pay attention to the social importance of achieving the law’s purpose as well as the social importance of preventing the harm to other constitutionally protected rights. Put simply, they must consider not only the benefits associated with the proposed decision but also the damage to other rights caused by it.

The Steps

Legitimacy Test

The legitimacy test is simply a requirement that the legal principle, right, or public interest which the decision would uphold is lawful and reasonable, and so it should not be dismissed right away. This step simply aims to filter out cases, which are to be decided on different grounds and for which the proportionality test would be therefore

obsolete. The second, third, and fourth sub-tests express the idea of optimization relative to the factual and legal possibilities, and so we will discuss them in more detail.

Suitability Test

The stage of suitability review examines whether there is a reasonable connection between the act that interferes with a right and its legitimate aim. The interference must be capable of contributing to the achievement of the legitimate aim at least to a small extent. The compliance with this requirement excludes the adoption of means which obstruct some right without promoting any other right or interest for which it has been adopted. The point of this stage is to sort out those cases where there does not actually exist a conflict of rights (or a conflict of a right and public interest). Naturally, a conflict of two rights means that one cannot realize one right without detriment to the other. If the interference with one right does not contribute to the realization of any other right then this interference would be merely an obstruction without any conflict of rights justifying it.

Necessity Test

The stage of necessity reviews examines whether the proposed legal act impairs an affected right as little as possible. The act is necessary if there are no alternative measures that may achieve the same purpose with a lesser degree of impairment. If there is an equally suitable means that interferes with the affected right less intensively, then things can be improved without any costs. The necessity requirement postulates that no such free lunch is left on the table. So, this sub-test requires that of two means promoting the same aim (a certain right or public interest) to the same degree, the one that interferes less intensively with a conflicting right, i.e., generates lower costs, has to be chosen. This shows that the necessity stage is an expression of the idea of efficiency.

Balancing Test

While the stages of suitability and necessity essentially involve optimization relative to the factual possibilities, the stages of legitimacy and balancing (proportionality in the narrower sense)

refer to what is legally possible. Balancing, the last stage of the proportionality test involves optimization relative to the competing rights. The greater the degree of non-satisfaction of, or detriment to, one right, the greater is the required importance of satisfying the other right for the balancing test to tilt in its favor (Alexy 2002, p. 102). This requirement excludes an intensive interference with one right that is justified only by a low importance assigned to the satisfaction of the colliding right.

The process of balancing can be broken down into three steps. (i) In the first step, the degree of non-satisfaction of or detriment to a right is established. (ii) The second step consists of establishing the importance of satisfying the competing right. (iii) And in the last step, it is examined whether the importance of satisfying the latter right justifies the detriment to or non-satisfaction of the former.

These three steps of balancing are more explicitly captured by the weight formula:

$$W_{i,j} = \frac{I_i \cdot W_i \cdot R_i}{I_j \cdot W_j \cdot R_j},$$

where i and j index the colliding principles, I_i and I_j capture the intensity of interference in the respective rights in case of a decision in favor of the other right, W_i and W_j represent the abstract weights of the two colliding principles, and R_i and R_j capture the reliability of empirical assumptions on both sides of the argumentation (Alexy 2014, pp. 55–56). If the weight is greater than one, principle i should prevail; if it is less than 1, the court should rule in favor of principle j .

The data entering the formula is necessarily imprecise and based on court's judgment. This, however, stems from the very nature of the decision problems that courts face and does not invalidate the balancing approach itself. To illustrate how such balancing can be approached, Alexy (2014) suggests to use the triadic scale often used in the constitutional discourse: light (l), moderate (m), and serious (s). The levels of this scale can then be mapped to a numeric scale with more than proportional increments, such as the geometric sequence such $2^0, 2^1, 2^2$. This captures the idea

that the power of principles increases with the intensity of interference more than proportionally (the “marginal cost” of interference is increasing).

Incommensurability Criticism

At a first glance, it looks like the proportionality test requires the judges to reconcile irreconcilable interests: the freedom of expression versus the right to good reputation, the protection of public safety versus the right to personal privacy, the protection of natural environment versus the freedom of business, the protection of public order versus the freedom of religion, the right to a fair trial versus the economic efficiency of judicial process, and so on.

An important objection against the proportionality test is that the idea of balancing presupposes comparing rights as value bearers without a common metric. The main point of this line of criticism is that the balancing of rights (or the public interest) compares items which are “incommensurable” (see Chang 1997, 2013; Frank 2008; Raz 1986, Chap. 13). The late US Supreme Court Justice Antonin Scalia, who may count as one of the pronounced proponents of the incommensurability objection, put it bluntly: “[T]he scale analogy is not really appropriate since the interests on both sides are incommensurate. It is more like judging whether a particular line is longer than a particular rock is heavy” (Bendix Autolite Corp. v. Midwesco Enterprises 1988).

This variant of the incommensurability objection is based on intuition that we can only compare two things of the same kind so that it is impossible to perform a rational cardinal comparison between gains and losses for colliding rights or the public interest that are incommensurable. How convincing is this objection?

We suggest that the famous idiom about the comparison of apples with oranges should not be used in a mechanical way because comparing things of different kinds can, indeed, be meaningful. Incommensurability need not imply incomparability (Da Silva 2011, see also Chang 2002). Balancing can work in a satisfactory manner as long as comparability among the colliding rights

is rationally justified, no matter whether they are commensurable or not. And for this we would need to know what exactly we are actually comparing during the balancing exercise.

The answer to that may be relatively straightforward. We compare the marginal social importance in fulfilling one right and the marginal social importance in preventing the harm to another right (Barak 2012, p. 484). However, the problem here is that “[i]dentifying a single criterion does not eliminate incommensurability if the application of the criterion depends on considerations that are themselves incommensurable” (Endicott 2014, p. 311). And so one can still be legitimately worried that if the judges are required to balance things that cannot be compared, then the conclusion of such a balancing is nothing more than the outcome of their arbitrary preferences or subjective feelings (Alder 2001, p. 717).

The severity issues raised by the incommensurability criticism notwithstanding the problem with this argument as, we see it, is twofold: First, if one needs to make a decision, it is not of much help to point out that the decision problem is difficult or impossible to crack. One can contemplate indefinitely what is the proper course of action in the trolley dilemma (Edmonds 2014) as long as this happens in a thought experiment. When, however, the trolley is actually hurtling down a track toward the five people tied to it, a decision has to be made whether to push the fat man over the bridge, saving the five, or let them die, saving the fat man. Courts are not in the business of thought experimentation; they need to make the actual decisions.

The second problem with the incommensurability criticism can be seen when we bring it *ad absurdum*. One may argue that individuals make decisions based on comparisons of incommensurable courses of actions on a daily basis. Should I order a steak or a salad? Should I snooze the alarm or get up right now? Should I stay in the office or give my dog a proper walk? It is hard to see how these decisions are made using some common objective scale. Indeed, all of these choices are different from one another along different dimensions, some of which they may not share, making it hard to argue that there is a common “objective”

denominator in any of these dilemmas. If the incommensurability argument was valid, all peoples’ choices could be regarded as purely incidental. Such an argument would be problematic not least from the legal point of view as the bulk of law presupposes individual rationality and the ability of people to make sensible choices for themselves (see Chang 2012).

Conclusion

When individuals choose the desired course of action, they do so based on their preferences or feelings. The courts are not in a fundamentally different position in this respect, save for two important aspects: (i) unlike individuals who decide for themselves, judges sometimes must make decisions on behalf of the society, and (ii) unlike individuals who face the consequences of their own decisions, the consequences of judges’ decisions are born by the society at large or other persons. This makes adjudicating hard cases more delicate, difficult, and prone to error. Indeed, judges are entrusted with decision tasks that people seldom face in their private lives. Proportionality approach forces the judge to explicitly articulate whether and why she evaluates the desired effects of her decision as proportional with respect to the undesired limitations the decisions implied for the other rights, using a common, if abstract, metric for such a comparison and to do so in a manner that is methodical and consistent across cases (see Klatt and Meister 2012).

Proportionality test does not need to deliver a rock solid solution in every case in which it is conducted. Indeed, the test may sometimes yield an ambiguous result. Referring to our weighting formula, this would happen when the resulting weight is equal to one or when alternative but plausible assumptions behind the individual entries (i.e., uncertainty) produce different outcomes of the test. In such stalemate situations, there is no way out other than court’s discretion to decide either way (Alexy 2014, see also Chang 2002; Da Silva 2011; Raz 1999, Chap. 3). It goes without saying that where the test is valuable is precisely in cases where it points one direction

with enough certainty. It is these cases where it helps the court to make a sound decision and avoid a bad trade-off.

Incommensurability criticisms raise valid points about the fundamental challenges associated with the proportionality test. Indeed, detailed awareness about the problems concerning the determination of the relative value of rights and infringements may improve the quality of courts' deliberation. However, pointing out that two rights are not commensurable is not very helpful when the court has to decide between them somehow. In the absence of availability of a better alternative decision algorithm, the proportionality appears to be the go-to solution. The value of the proportionality project seems to be in that it forces courts to articulate their arguments in an explicit, structured, and transparent manner so that the court's deliberation and final decision can be understood (Klatt and Meister 2012, see also Winter 2016), even if one might disagree with the weights assigned to individual elements in the weighting exercise.

Prosocial Behaviors

Sébastien Roussel

Department of Economics, CEE-M, Université Montpellier, CNRS, INRA, SupAgro, Université Paul Valéry Montpellier 3, Montpellier, France

Abstract

Prosocial behaviors contribute to the well-being of others following activities like charitable giving or volunteering. Theories that explain prosocial behaviors are pure altruism and impure altruism, inequality aversion reciprocity and conditional cooperation. These theories are linked to a system of motivations, that is intrinsic motivation, extrinsic motivation, and image motivation. Social norms play a key part in one's motivations to behave prosocially, in particular with regard to image motivation and likely sanctions when one's deviates from these norms. The expressive power of law leads to norms legitimacy. Prosocial behaviors are mainly studied in the literature in economics and psychology, especially in behavioral and experimental economics.

Definition

Prosocial behaviors refer to behaviors contributing to the interests of others and not to its own self-interest. Antisocial behaviors stand for the opposite of prosocial behaviors.

Introduction

From the seminal example of blood gift (Titmuss 1970) to the field of charitable giving (Bekkers and Wiepking 2011), many situations show that people act in a prosocial manner. Prosocial behaviors contribute to the well-being of others following activities like charitable giving (monetary giving or sharing for example), volunteering, voting, etc. List (2011) highlights that, in a regular year, total charitable gifts of money represent 2% of the US Gross Domestic Product (GDP), e.g., worth \$314 billion in 2007. This latter figure has been increasing to reach consecutive records in 2014 and 2015, with an estimated \$373.25 billion in 2015 (Giving USA 2016).

In terms of the history of economic thought, prosocial behaviors have been originally considered through Adam Smith's visionary overview of one individual's rationale. Smith (1759) stated that: "How selfish soever man may be supposed, there are evidently some principles in his nature, which interest him in the fortune of others, and render their happiness necessary to him, though he derives nothing from it, except the pleasure of seeing it" (cited by Meier 2007) with regards to "*the passions and motives which influence it*" (cited by Bénabou and Tirole 2006). This interpretation of rationality already suggested that decision-makers are not always egoistic. Consequently, one may analyze the role of social preferences/other-regarding preferences and motivations leading to prosocial behaviors (section "[Social Preferences and Motivations](#)"), as well as the part played by the institutions and the legal framework through social norms and the expressive function of law (section "[Social Norms and Laws](#)"), and how economics model and assess these behaviors (section "[Modeling and Assessing Prosocial Behaviors](#)").

Social Preferences and Motivations

In a detailed survey, Meier (2007) underlines the economic theories that explain prosocial behaviors through social preferences. These theories are respectively: pure altruism (Eckel and Grossman 1996) and impure altruism (Andreoni 1990), inequality aversion (Fehr and Schmidt 1999), reciprocity (Rabin 1993), and conditional cooperation (Frey and Meier 2004). While pure altruism and inequality aversion refer to situations where individuals act themselves selflessly, impure altruism, reciprocity, and conditional cooperation suggest that individuals expect to get something back from their prosocial activities.

The theories involving social preferences are linked to a system of motivations that result in prosocial behaviors in different ways. Ariely et al. (2009) describe the set of motivations that leads people to adopt prosocial behaviors. These motivations are in a broad sense: intrinsic motivation, extrinsic motivation, and image motivation. Intrinsic motivation refers to prosocial preferences like altruism, while extrinsic motivation indicates how external factors like monetary rewards matter in acting prosocially. Image motivation deals with the impacts of the others' perception and the individual's self-esteem on prosocial behaviors, and how this may frame one's behavior. However, the interplay between these motivations is critical. For example, many studies in economics and psychology show how intrinsic and extrinsic motivation may be complement or substitute, leading to crowding in – crowding out phenomena (Frey and Oberholzer-Gee 1997). This is also linked to the key role played by social norms.

Social Norms and Laws

Social norms play a key part in one's motivations to behave prosocially, in particular with regard to image motivation and likely sanctions when one's deviates from these norms. Social norms rely on a consensus towards acceptable behaviors (Elster 1989; Fehr and Schmidt 1999). Viscusi et al. (2011) characterize social norms "in terms of what is normatively appropriate rather than what

is the conventional mode of behavior,” and study how personal and external norms matter in recycling behavior. Another classical distinction refers to injunctive norms and descriptive norms, where the former characterizes the perception of what should be socially approved, and the latter characterizes the perception of what is effective. What is at stake is to conform or not to these norms, along with the individual valuation of what is morally good or wrong, and how these norms are enforced. Besides, identity plays a meaningful role while individuals follow prescriptions or social norms to secure their self-concepts (Akerlof and Kranton 2000).

The institutionalization of social norms into laws has been underlined by McAdams (2015) through the expressive powers of law, allowing for the recognition of good behavior versus bad behavior, leading to injunctive norms legitimacy. Moreover, he shows that law contributes to a coordination function, discloses information and beliefs, and provides compliance rules as explicit incentives. This was previously highlighted in the literature by the expressive function of law (Sunstein 1996a, b). Public authorities disclose the social meaning of one’s activities to help people make desired choices in a so-called norm management. In addition, Funk (2007) provides an empirical analysis of voting turnout and identifies the greater impact on behavior when law targets at the civic duty.

Modeling and Assessing Prosocial Behaviors

Prosocial behaviors are mainly studied in the literature in economics and psychology, especially in behavioral and experimental economics. Participation in prosocial activities is then traditionally modeled as a contribution to a public good (Andreoni 1990). Regarding the expressive content of laws, it has been shown how this can be modeled in the presence of norms or reputational rewards following Bénabou and Tirole (2006, 2011). In the literature, economic games are used in experiments to test hypotheses on social preferences and motivations that lead to prosocial

behaviors. In these experiments, a prosocial behavior like giving more is desirable (monetary or non-monetary contribution), and economic incentives relying (or not) on intrinsic, extrinsic, and image motivations can be implemented.

Traditional economic games used in the experiments on prosocial behaviors are mainly the ultimatum game, the (repeated) public good game, or the dictator game. For example, the dictator game allows testing individual generosity (List 2007), where the recipient must accept the sum offered by the dictator; consequently, the dictator’s behavior is then not strategic. It has also been shown that a social link between the dictator and the recipient increases the incentive to donate (Engel 2011), in particular when the recipient is a nongovernmental organization (NGO) like the Red Cross (Eckel and Grossman 1996). Furthermore, psychological and biological factors drive prosocial behaviors in expressing the motivations stated above. Moods and emotions do influence prosocial behaviors in various ways. For instance, gratitude plays a key role in building relationships and shaping costly prosocial behaviors (Bartlett and DeSteno 2006), awe increases donation amounts (Ibanez et al. 2017), whereas anger can impact negatively these behaviors (Drouvelis and Grosskopf 2016). With regards to the impact of laws on behavior, Galbiati and Vertova (2014) show from alternative public good games that obligations (laws and other formal rules) and economic incentives are complementary to incentivize cooperative behaviors.

Abstract

The market for sex is a contentious one, and has often been subject to heavy regulation. This chapter goes through factors that are important with regards to the demand for and supply of prostitution. A particular focus is on the relationship between laws and the quantity of sex bought and sold. The most common way that laws have been used to affect the demand for prostitution is by outright criminalization, which may lead to less prostitution, but may also drive the activity further underground. The effect of criminalizing prostitution on trafficking is ambiguous since criminalization may also lead to a substitution effect towards more trafficked prostitutes. Scarcity of reliable data is one of the main challenges for the study of prostitution.

Definition

The demand and supply of prostitution

Introduction

Buying and selling of sex can be analyzed as any regular economic exchange. The demand side is made up of customers who compensate the suppliers, prostitutes, for the commodity, or service, of sex. This all takes place within some regulatory framework.

The market for sex is a contentious one and has often been subject to heavy regulation. Both these facts have spurred academic research, as this chapter will show. However, the field has until recently not been very well developed, mostly because it has been plagued by a scarcity of reliable data. The lack of data is due to both the fact that prostitution in many societies is illegal or just at the margin of being illegal and the social stigma attached to being associated with the trade.

This chapter goes through factors that have found to be important with regard to the demand for and supply of prostitution. A particular focus is on the relationship between laws and quantity of sex bought and sold. It ends with an identification of gaps in the literature and a discussion of some underexplored questions and fruitful avenues for further research.

Demand

Amenable to Change Through Laws

The most common way that laws have been used to affect the demand for prostitution is by outright criminalization. The possibility of a penalty is an unambiguous (expected) cost for a potential buyer and will lead to less prostitution. This mechanism is confirmed empirically by Jakobsson and Kotsadam (2012), who investigate the effect of criminalization of buying sex on the amount of sex bought. Using longitudinal data from Norway and Sweden and employing a difference-in-differences approach, they estimate that the criminalization of buying sex in Norway in 2009 leads

to a downward change in the amount of sex bought of 3.5% points. They do not find an effect on attitudes in this sample and conclude that the most likely mechanism is an increased risk of getting caught. A serious problem in this type of studies is that they rely of self-reporting, in particular self-reporting of activities that are not only highly stigmatized but also change legal status during the period investigated. The authors also use different types of measures, one direct whereby people are asked if they had bought sex during the last 6 months and one more indirect where the respondents are asked if they know someone having bought sex during the last 6 months. While it is likely that respondents are more likely to report on people they know, it is still an inherent problem that the people they know perhaps keep such information more to themselves after it has become illegal.

If demand is relatively inelastic, criminalization of clients may to a large extent drive the activity further underground, with a corresponding increase in risk and worsened working conditions for prostitutes.

Laws may also have a normative function. In particular, it may have an expressive function in signaling a society's beliefs about what is considered acceptable behavior. Jakobsson and Kotsadam (2011) analyze whether the criminalization of buying sex in Norway in 2009 affected attitudes to prostitution. Again using longitudinal data from Norway and Sweden and employing a difference-in-differences approach, they find that the law made people in the capital more negative toward buying sex, but no effect on moral attitudes in the aggregate. They explicitly relate this to a framework whereby people that are most affected by legal changes are most likely to change their attitudes and argue that since people in the capital area were more exposed to street prostitution before the law and saw a large immediate reduction afterward, they should be more likely to be affected. They also find that young people were more affected in their attitudes by the law, which they link to socialization theory arguing that young people are more adept to changing their moral values. On the other side, passing laws that are difficult to enforce or against which there

is significant disagreement may weaken the respect for laws in general.

Della Giusta et al. (2009b) model reputation and stigma explicitly. Loss of reputation may be incurred by both buyers and sellers of sex and reduce the amount of sex exchanged. As described in the studies above, moral attitudes may not be very responsive to the law, but criminalization certainly carries social stigma in itself. Although Jakobsson and Kotsadam (2012) do not find an effect on moral attitudes of Norway's prostitution law, it is possible that the law increased the stigma related to buying sex and thereby added to the formal penalty. Della Giusta (2010) suggests that politicians adopt overly repressive regimes to please conservative swing voters.

Della Giusta et al. (2009a) delve empirically into the demand side and find that stigma does play an important role. They also find that demand may be multifaceted, e.g., in terms of risk preferences, and stress the importance of recognizing this when designing policy.

Important Factors Less Responsive to Legal Change

Insofar as sex is a normal good, the amount bought depends positively on an individual's income. However, prostitution is more common in poor countries. This will often have to do with supply, discussed below, but higher income of the customers may also decrease prostitution. Edlund and Korn (2002) propose a theoretical model in which increases in male (customer) income decrease the number of prostitutes because men prefer women as wives rather than as prostitutes. Relatedly, men's marriage opportunities may to a large extent determine their demand for prostitution and itself be determined by income, although married men constitute a large share of the demand. This suggests that policies and regulations promoting stable employment opportunities and a social safety net are relevant tools for authorities concerned with prostitution.

Noncommercial nonmarital sex and commercial nonmarital sex are typically thought of as substitutes for marital sex (Edlund and Korn 2002), but the relation between commercial and

noncommercial nonmarital sex is ambiguous. On factors such as pornographic material, a society's sociosexual culture, and the distinctness of gender roles, there is also little consensus.

Sex ratios in the population are also thought to be important. Places where men have outnumbered women to a significant degree have largely seen more prostitution. As Edlund and Korn (2002) point out, these places have tended to consist of men in transit, who participate only in a locality's sex market and not in its marriage market.

Supply

In some countries, selling sex is illegal while buying is legal, but a number of countries maintain the illegality of both sides of the market. When selling sex is illegal, the potential prostitute faces formal sanctions in addition to social stigma. The occupation of prostitute is thus made less appealing, and the woman in question is perhaps led to consider other even less desirable options. If prostitution does not entail any negative externalities and criminalizing selling sex is bad for women in the business, lawmakers should of course think twice before enacting such laws. What women do, and even if they do change occupation, after it becomes illegal is, however, unknown, but there are indications of severe externalities in terms of sexual trafficking, so a firm policy conclusion cannot be reached at this stage.

The most obvious factor affecting the supply of prostitution is income relative to other occupations and in general employment opportunities for women. As with any other type of work, the better potential labor market elsewhere, the less supply there will be of workers in a particular trade. As with the demand side, this suggests a role for providing employment opportunities and a social safety net in reducing prostitution. Other factors that impact the profitability of prostitution are sex ratios and inequality. To the best of our knowledge, there are no empirical studies investigating these issues.

Another standard factor in occupational choice is working conditions. As an effect of being

undertaken outside the formal economy, prostitution has often lacked regulation and oversight. In general, prostitutes face a more risky working environment than other laborers. In Europe, a significant minority of countries have legalized prostitution and tried to regulate the industry (Jakobsson and Kotsadam 2013). Safe working conditions, access to health services, and the rights to public benefits are all factors that make prostitution relatively more tempting. Regulations denying these to an occupation, as is largely the case for prostitution, can therefore be expected to lead to less selection into that profession. Any form of criminalization will likely lead the mere advocacy of basic rights and labor standards more difficult.

Prostitution is distinct from most other professions in that it carries a significantly higher opportunity cost in terms of social stigma. Della Giusta et al. (2009b) model reputation explicitly. Criminalization will mostly affect the stigma attached to the side or activity that is criminalized; however, it might spill over to other sides as well. For instance, outlawing buying of sex could increase the stigma not only of buying sex but also of selling. Edlund and Korn (2002) stress foregone marriage opportunities as the most important opportunity cost of prostitution. This is due to limited mobility between the marriage and prostitution sectors, a feature that also explains prostitutes' relatively high (up-front) wages. However, Arunachalam and Shah (2008) find no empirical support for the marriage-based explanation of the earnings premium in sex work.

There have been many instances in which women have been coerced to work as prostitutes. Forced labor is now outlawed in almost all countries – prostitution legislation aimed at alleviating this problem has therefore often been aimed at restricting the market, in the hope that this will hurt the potential profits of traffickers. Related to this, there has recently been developed a separate literature on trafficking. Although any kind of criminalization will reduce prostitution, the effect on trafficking is ambiguous, since criminalization may also lead to a substitution effect toward more trafficked prostitutes (Cho et al. 2013). Jakobsson and Kotsadam (2013)

and Cho et al. (2013) investigate this question using cross-country data and case studies and find that harsher sex laws are associated with less trafficking.

Notwithstanding the problem of forced labor in the sex trade, a significant part of international sex labor migration can be seen as voluntary and economic in motivation. Thus, policies that promote freer movement of labor and fewer restrictions on travel can be expected to increase the amount of prostitution. On the other hand, better opportunities to freely travel and search for other jobs may reduce the possibilities of human traffickers to exploit or deceive vulnerable migrant and force them into the sex trade.

A general issue with regard to trafficking is the tension between the welfare of potential trafficking victims and that of current prostitutes. Restricting the market for prostitution, either through the denial of benefits to prostitutes or some form of criminalization, is likely to lead to prostitution being less profitable and thus less tempting for traffickers but is also likely to hurt those currently in the profession. Lee and Persson (2013) propose a regulatory framework that provides a solution to this conundrum: licensing prostitutes and criminalizing buying sex from unlicensed prostitutes. This model deters demand for nonvoluntary prostitutes and thus reduces the potential profit for traffickers while at the same time safeguarding the interests of licensed prostitutes.

Technological change has impacted the prostitution market. Cunningham and Kendall (2011) examine the use of the Internet in the prostitution business. They find that online soliciting has displaced some of the off-line market but that the net effect is an increase in supply. They also find that prostitutes soliciting online are largely engaging in lower-risk behaviors than their street-level counterparts, although former street workers may retain their higher-risk behavior also online.

Gaps in the Literature

Scarcity of reliable data is one of the main challenges for the study of prostitution. Collection of

new, reliable data is one of the most worthwhile initiatives with regard to prostitution research. This could be in the form of surveys, anonymous if necessary, but in societies where prostitution is legal, the ambitions should be even higher. For instance, if the framework of mandatory registration of legal prostitutes proposed by Lee and Persson (2013) is adopted, data from those registration procedures should be collected, kept safe, and be available for researchers. In general, regulation will help data collection, due to the fact that one is not collecting data on something criminal and that there will be data emanating from the enforcement of regulations, whether they are about working conditions, health, or taxes.

Even where prostitution is not legal, there are opportunities to collect more and better data and develop better measures, for instance, through the use of list experiments (also called list treatment or the item count technique).

There has been little research on how different forms of criminalization or regulation affect the working conditions of prostitutes. Di Tommaso et al. (2009) use data from the Anti-Trafficking Unit of the International Organization for Migration and find that the well-being of trafficked women is (further) worsened when having to work in secluded spaces.

Criminalization legislation is often the result of an alliance between one side consisting of people who are opposed to prostitution as a matter of principle and another that is concerned about coercion of involuntary prostitutes. The stability of this alliance remains an open question.

Whether demand for voluntary and non-voluntary prostitutes is uniform is an important question that has not been much studied. For instance, if a substantial share of demand is for the voluntary product, that would be valuable to take into account when designing regulation, as shown theoretically by Lee and Persson (2013). Della Giusta et al. (2009a) take some steps toward disaggregating the demand side, but they do not specifically focus on if demanders care about voluntariness.

There are also ways in which the supply side can be disaggregated further. Globalization has made movement across borders easier. Cho

et al. (2013) and Jakobsson and Kotsadam (2013) investigate the relation between sex laws and trafficking, but it would be valuable to know also about the more direct relation between the enforcement of laws against trafficking and coerced labor on the one side and involuntary trafficking on the other.

Topics on which some hold strong moral attitudes can easily become politicized and subject to limited inquiry. So also with prostitution; it is therefore particularly important that researchers in this field are allowed to remain independent when addressing the topics described in this chapter.

Protective Factors

Norbert Hirschauer¹ and Sebastian Scheerer²
¹Agribusiness Management, Institute of Agricultural and Nutritional Sciences, Martin-Luther-University Halle-Wittenberg, Halle (Saale), Germany

²Institute for Criminological Social Research, Faculty of Economics and Social Sciences, University of Hamburg, Hamburg, Germany

Abstract

Protective factors help people achieve positive outcomes despite exposure to potentially negative influences (in medicine, good health in spite of smoking cigarettes; in the social sciences, productive adult lives as law-abiding citizens despite adverse conditions during childhood and adolescence). In Law and Economics, the concept, in conjunction with control theories, contributes to a better understanding of why economic actors obey the law and comply with rules despite exposure to material incentives to the contrary. Protective factors can result from external sources (social control) and internal sources (internalized conventional values). They generate nonmaterial benefits in the case of compliance and/or non-material costs in the case of noncompliance. The inclusion of protective factor into regulatory analysis – in combination with the consideration of risk factors that work in the opposite direction – helps to understand why some

regulatory regimes work better than others. The concept can be especially useful when it comes to designing regulatory innovation based on a better understanding of why some economic actors obey the law and others don't.

Definition

Protective factors are individual and/or environmental characteristics that reduce people's vulnerability to adversities such as natural, health, or moral hazards.

Protective Factors in Law and Economics and Criminology

Conceptual Background

The concept of *protective factors* owes its existence to the attempt to explain the curious fact that some people experience positive outcomes in the face of highly adverse conditions. If some heavy smokers, for instance, manage to live in good health until their 90th birthdays and beyond, then it is plausible to assume that there is something – some kind of protective factor – that shielded them from contracting any of the diseases commonly associated with inhaling the toxic mixture of over 4,000 chemicals called cigarette smoke. Analogous phenomena of *resilience* can be found in relation to delinquent life trajectories. The quest to explain surprisingly positive life courses of people from dysfunctional families and highly delinquent neighborhoods will reveal characteristics and/or resources that worked in favor of these individuals and guarded them against negative influences. Protective factors may also play a role in the context of *Law and Economics* and, more specifically, rational choice theories. Here, the concept can explain why (some) people obey rules in spite of *moral hazards* and an abundance of profitable and convenient opportunities to break them, i.e., despite an environment with a high degree of adversity to *compliance* with rules.

When using the term “protective factor” in *Law and Economics*, one implicitly resorts to

principal agent theory and adopts the dichotomous perspective of a *principal* (e.g., a lawmaker or regulator) who has defined two types of *agents'* behavior with regard to a rule: noncompliance (undesired behavior) as opposed to compliance (desired behavior). The concept's analytical potential is especially useful when the term "protective factors" is limited to designate nonmaterial factors associated with social control and internalized norms that encourage compliance in an environment where material factors would favor noncompliance. This requirement is met by the following definition:

Protective factors are characteristics in individuals and/or their socio-economic environments that discourage actors from rule-breaking by causing non-material benefits (utility) in the case of compliance and nonmaterial costs (disutility) in the case of non-compliance.

This definition is a useful tool to transcend an all too *narrow rational choice* conception with its restrictive assumption of *utility* hinging exclusively on material wealth. It turns our attention to the fact that not only law works "as a means for changing relative prices attached to individual actions" (Parisi 2004, p. 262), but that there are also nonmaterial factors influencing those "prices" for the individual actor. It corresponds with the understanding that people often pursue multiple goals and strive not only for wealth but also for *social recognition* and distinction as well as for consistency with their *internalized values* and identity (Lösel and Bender 2003; Akerlof and Kranton 2010). Depending on the situation, utility gains from complying with rules may, or may not, outweigh temptations to break them (Pinstrup-Andersen 2005). In other words, the utility of multi-goal decision-makers with *bonds to social norms* is not in all cases monotonically increasing

in expected material wealth. Instead, such actors are prepared to pay an *ethical premium* that shields them from deviance if – but only if – it exceeds the economic temptation to break the rules. The ethical premium is the utility outcome produced by protective factors. It provides an operational definition of resilience which, in turn, is the antonym of *vulnerability*: The stronger an individual's protective factors, the higher her/his ethical premium and the higher (lower) her/his resilience (vulnerability) to moral hazards.

Figure 1 illustrates that we can distinguish four classes of protective factors: On the one hand, there are factors that provide nonmaterial benefits to the individual in case of compliance. These benefits may result from (1) external sources (e.g., social respect) or (2) internal sources (e.g., self-respect). On the other hand, there are factors that cause nonmaterial costs in the case of non-compliance. These costs may also have (3) external sources (e.g., ostracism) or (4) internal sources (e.g., conflict with self-image).

Adopting the perspective that, besides economic wealth, people may seek social respect and inner contentment necessarily requires juxtaposing protective factors with their opposite that has been labeled *risk factors* (and is sometimes also referred to as *criminogenic factors*). Risk factors can be defined as follows:

Risk factors are characteristics in individuals and/or their socio-economic environments that encourage actors to break rules by causing non-material benefits (utility) in the case of non-compliance and nonmaterial costs (disutility) in the case of compliance.

Analogous to protective factors, four classes of risk factors can be distinguished: An individual's integration into a deviant subculture, for instance, may provide (1) nonmaterial external benefits for

Protective Factors,

Fig. 1 A decision-theoretic classification of protective factors

the rule breaker (e.g., respect by deviant peers). A lack of conformity with the values behind the rules (termed conventional in the rest of this essay) or an outright internalization of deviant norms may generate (2) nonmaterial internal benefits for the deviant individual (affirmation of the deviant self). Prominent examples are illicit behavior due to *reactance* (Brehm 1966; Miron and Brehm 2006) and *altruistic rule breaking*. (3) Compliance in such settings, in contrast, may give rise to ostracism by the deviant peer group and (4) cause conflict with the individual's deviant self-image. In brief, nonmaterial costs for obeying rules and nonmaterial benefits for disobeying can be conceived as individual-level consequences of risk factors that would cause illicit behavior even in the absence of economic temptations to break the rules (hence, the alternative label "criminogenic factors").

Including the term "risk" into the label that has been attached to the nonmaterial factors encouraging deviance reflects three important conceptual aspects: First, risk factors are conceived as random variables. Second, they impact the probability distribution of the behavioral outcome (i.e., the *behavioral risk*). Third, there is an unambiguous direction of influence: Risk factors increase the probability of the undesired behavior on the part of the agents. While not semantically reflecting the aspect of risk, protective factors share the first two qualities of risk factors: They are random variables and they impact the behavioral risk.

They work in the opposite direction, however, and decrease the probability of the undesired behavior.

In empirical research on how protective factors and risk factors jointly impact behavioral risks, we will encounter three unknowns: the protective factors and risk factors that are at work in a specific context, the level of these factors, and, equally important, the interactions and functional forms that link them to utility. It will thus be doubtlessly difficult to quantify how much utility people derive from nonmaterial sources in given contexts. We know, however, that they will only abstain from profitable rule breaking if their willingness to renounce profits (ethical premium), as resulting from the balance of protective factors and risk factors, exceeds the monetary benefits from illicit behavior.

Adopting a *ceteris paribus* perspective and thus abstracting once again from risk factors (and their interaction with protective factors), Fig. 2 illustrates how protective factors work: An individual's utility for rule abidance as opposed to rule breaking increases monotonically in the level of some upstream variable acting as a protective factor. The precise form of the functional relationship varies depending on factor and context. In the simplest case, it will be linear as depicted in (a). If the functional relationship is to reflect a self-reinforcing mechanism, it will be exponential as depicted in (b). If a threshold needs to be exceeded before a protective factor generates a significant

P

Protective Factors, Fig. 2 Functional relationships linking protective factors to utility and behavior

impact, the function will include a clear discontinuity and may be divided into two linear segments as depicted in (c).

Finally, it should be noted that even a *broad rational choice* conception that includes utility derived from social recognition and inner harmony is often insufficient to explain and predict – with reasonable success – the behaviors of people facing specific rules and specific contextual conditions. Instead, one needs situation-specific models or “minitheories” (Korobkin and Ulen 2000) that facilitate a reconstructing understanding of idiosyncratic or group-specific decision-making processes in particular real-life contexts. Such models do not have to be isomorphic with respect to the “objective” rules of the world but to the world as subjectively perceived and evaluated by the individual or specific subpopulation under consideration (Rubinstein 1991). In other words, one needs models that tackle the gap between narrow rational choice predictions and actual behavior (Garoupa 2003). Such models need to reflect behavior as the result of *multi-goal* decision-making by (potentially) rule breaking and *bounded rational* actors (cf. Simon 1957; Gigerenzer and Selten 2001) who *subjectively* form expectations and evaluate likely outcomes at the time they make their choices.

Levels of Analysis

The decision-theoretic definition of protective factors provided above facilitates an operational understanding of their utility outcomes and a clear separation from risk factors. Focusing on the utility outcomes of the individuals under consideration, however, does not yet tell us which real-life characteristics produce these outcomes and thus make people resilient to the seductive potential of illicit behavior. Figure 3 describes the different levels of the *cause-effect chain* on which these factors can be found.

On a first upstream level in the cause-effect chain, we can distinguish external causes of utility (social respect and recognition, social disrespect and ostracism) from internal causes (self-respect and self-affirmation, self-disrespect and self-loathing). Regarding external utility sources, a

conceptual distinction between a given level of respect/disrespect shown by others and the individual’s evaluation of that level may be useful. It does not seem to make sense, however, to attempt an operational distinction between a given level of one’s own self-respect/self-disrespect and one’s own evaluation of that level. At best, it would require a schizophrenic separation of the self in two parts.

On a second upstream level of the cause-effect chain, four major types of factors acting as protective mechanisms and determining the factors on the first level have been distinguished (Hirschi 1969): first, social integration into conventional society and emotional bonds to relevant others (elders and peers) who cherish rule abidance and repudiate rule breaking (*attachment*); second, hostage posting to conventional society through reputation as an honest business person or holder of public office that has been accumulated from earlier “investments” in conventional life and that is lost if outlawed behavior is disclosed (*commitment*); third, engagement in conventional activities that consume time and mental energy and thus help the individual abstain from the often complex and time-consuming actions of rule breaking (*involvement*); and fourth, identification with the conventional system of values that are “behind the rules,” including the recognition of authority, the emulation of role models, and an appreciation of rule abidance in itself (*beliefs*).

Going further back the causal chain, attempts have been made to systematize protective factors “behind” the factors on the second level. They all list and classify variables believed to be positive influences still further upstream. Commonly used classifications categorize these upstream factors into domains such as *peers*, *community*, *family*, and *individual*. Accordingly, variables such as long-lasting relationships and trust in the (business) community, a functioning social fabric in neighborhoods and families, low existential stress, and emotional stability are listed as protective factors. All these compilations face the difficult task to avoid gaps, duplications, and inconsistent listings of variables that, while representing behavioral correlates such as gender

Protective Factors, Fig. 3 Protective factors: cause-effect chain and levels of analysis

or ethnic affiliation, are either not causes of behavior in the sense of this word or situated on different levels of the cause-effect chain. As indicated in Fig. 3, one could go even further back in time and causation and compile protective factors on still further upstream levels. Whatever the focal level of analysis, inconsistent listings are futile descriptive exercises with little practical potential to indicate the variables that preventive strategies could, and should, tackle to produce more compliant behavior.

Relation to Control Theories

The decision-theoretic concept of protective factors can be linked to the view of human nature in criminological *control theories* (cf. Hirschi 1969;

Gottfredson and Hirschi 1990; Tittle 2000). Contrary to conventional criminological theories, which used to explain crime and deviance by searching for criminogenic factors in the delinquent subject and her/his environment, control theories contend that it is not the breaking of rules that needs explanation in the first place but rather compliance. In the view of control theorists, humans are basically free to deviate from rules following their own interest. It is therefore the challenge of every society to gradually and effectively “deprive” individuals of their original freedom to deviate by creating bonds that make it increasingly difficult for a well-socialized member of society to act against social and legal restraints.

In their attempts to understand the processes by which societies deprive people of their original freedom to deviate, control theorists analyze how social bonds are created through both the attachment to others and the internalization of value systems in line with social expectations. While the former generates external (social) control and rewards/sanctions, the latter leads to internal (self-)control and rewards/sanctions. If society fails to create sufficient social bonds, man’s self-interest and original freedom to deviate, in conjunction with economic temptations, continue to induce rule breaking. Table 1 summarizes the core concept of control theories using an illustrative numerical example.

Our point of departure is an individual who faces a misdirected incentive of –80 (economic temptation) to break some rule. Due to protective factors – both in the form of bonds to relevant others and internalized values – the individual is prepared to pay an ethical premium totaling 55. Since this premium does not exceed the economic temptation, we would conclude that the individual is not sufficiently shielded from the natural inclination of self-interested rule breaking. Reflecting the basic concern of control theories with the gaps

and holes in the system of social bonding and control, the numerical example in Table 1 is based on the assumption that deviant behavior (e.g., *white-collar crime*) is caused by economic temptations that coincide with lacking protective factors rather than by risk factors. This is why nonmaterial cost from obeying and nonmaterial benefits from disobeying, while being mentioned, are assumed to be zero.

Assuming risk factors to be inexistent may be an adequate analytical simplification in some situations; it may be completely inadequate in others. The degree of resistance to a given material temptation results, in principle, from the balance of protective factors and risk factors. An individual may, for instance, simultaneously be a member of social groups with conflicting value systems. As a result, she/he will strive not only for the social recognition within conventional society but also for the respect of deviant elders and peers, thus possessing external protective factors and external risk factors at the same time. Even two souls may be dwelling in an individual’s breast. An example would be a generally law-cherishing individual who, for some reason or another, feels an internal pressure to engage in altruistic rule

Protective Factors, Table 1 An illustrative example for the concept of control theories^a

	Utility for obeying		Utility for disobeying		Utility differential
Material benefits (+) and costs (–)		+700		+780	–80^b
External benefits (+) and costs (–) from social respect and disrespect in conventional society	<i>Protective factors</i>	+10	<i>Protective factors</i>	–25	+35 ^c
External benefits (+) and costs (–) from social respect or disrespect in deviant subculture	<i>Risk factors</i>	0	<i>Risk factors</i>	0	0
Internal benefits (+) and costs (–) from consistency and conflict with internalized conventional values	<i>Protective factors</i>	+5	<i>Protective factors</i>	–15	+20 ^d
Internal benefits (+) and costs (–) from reactance or internalized values of deviant subculture	<i>Risk factors</i>	0	<i>Risk factors</i>	0	0
Expected benefits (+) and costs (–) from nonmaterial sources		+15		–40	+55

^aFor risk-averse actors who deduct risk premiums from risky benefits and add risk premiums to risky costs, the figures are to be conceived as units of utility. For risk-neutral actors, they can be directly interpreted as payoffs and payoff equivalents.

^bThe negative sign of the differential indicates a misdirected incentive (economic temptation).

^cEthical premium caused by external sources.

^dEthical premium caused by internal sources.

breaking in a certain context. Another example would be a situation of reactance in which an actor finds inner satisfaction by breaking an imposed rule while simultaneously feeling uneasy or even guilty for breaking the law. In both cases, internal protective factors and internal risk factors are at work at the same time. While risk factors are conventionally considered in criminological research on juvenile delinquency and illicit drug use, they are often omitted from the analysis of economic deviance. However, reactance, deviant cultures, and the internalization of deviant norms can be important in business contexts too. Unless we have contrary contextual knowledge, risk factors should thence not be *a priori* ignored in the analysis of economic deviance.

The adequacy of a behavioral model depends on the context and the level of analysis (cf. Hess and Scheerer 2004). On the *macro-level* where one considers an industry's response to (a change in) rules, a narrow rational choice approach with its exclusive focus on economic incentives may, or may not, facilitate a realistic view. For an analysis on the *meso-level* of company decisions made by respected members of the business community, applying the rationale of control theories and abstracting from risk factors can be adequate but may not always be so. There may be more causes of white-collar crime, for instance, than just economic temptations and gaps in social bonds and social control (Katz 1988, pp. 310–324). *A priori* disregarding risk factors, however, is most plausibly inadequate not only when trying to understand juvenile delinquency but also in a *micro-level* analysis of individual employees who may face strong group cohesion and deviant corporate subcultures with informal social pressures and rewards to bend or break the law.

The extension of the narrow rational choice conception provided by the inclusion of protective factors and risk factors into the set of potential behavioral determinants can be related to Ostrom's (2005) "Institutional Analysis and Development Framework." Adopting an institutional economics focus on rule-governed social life, Ostrom attaches the label *delta parameters* to the nonmaterial benefits and costs that an

individual derives from her/his choices. That is, besides the utility derived from economic incentives (payoffs), emphasis is put on the utility (payoff equivalents) that people gain from external sources in terms of social approval or disapproval (positive and negative external deltas) and internal sources in terms of affirmation of, or conflict with, internalized values and self-image (positive and negative internal deltas). Given the obvious communication problems caused by the lack of a generally acknowledged terminology between the various behavioral science disciplines (here as well as in many other cases), one can but agree with Ostrom's own words, "If every social science discipline or subdiscipline uses a different language for key terms and focuses on different levels of explanation as the 'proper' way to understand behavior and outcomes, one can understand why discourse may resemble a Tower of Babel rather than a cumulative body of knowledge" (Ostrom 2005, p. 11).

Prevention of Rule Breaking

How people respond to rules is one of the core concerns of *Law and Economics* and regulatory theory. First of all, regulators have to understand existing compliance problems as resulting from the joint effects of economic incentives, protective factors, and risk factors that are at work at a given point in time. Regarding prevention and the *management of behavioral risks*, a reconstructing understanding of the status quo is but a starting point, however. To successfully manage behavioral risks and reduce the probability of first-time rule breaking as well as of recidivism, regulators need to identify effective and cost-efficient regulatory strategies. Their success in this endeavors – be they directed at certain target groups within risk-based preventive schemes (secondary prevention) or at individual offenders within personalized reintegration approaches (tertiary prevention) – depends on the ability to forecast behavioral changes that are likely to be brought about by hypothesized regulatory action.

While the protective factor concept is geared toward the analysis of compliance with given rules, one should keep in mind that, depending on the type of the behavioral determinant they are

primarily aimed to impact, four ideal types of regulatory regimes can be distinguished in the first place:

1. *Hierarchical command and control*, such as tight law enforcement, impacts the set of choices that are available to regulatees (e.g., through license withdrawal) as well as their relative economic competitiveness (e.g., through sanctioning).
2. *Incentive-oriented regimes*, such as steering taxes and payments handed out to those who undertake specified actions, increase the relative economic competitiveness of the socially desired behavior without imposing mandatory rules.
3. *Value-oriented regimes*, such as the promotion of corporate social responsibility and professional ethics, are based on persuasion and finally aimed to increase protective factors that shield regulatees from socially undesired behavior.
4. *Human capacity building*, such as counseling and training, is to enhance the actors' abilities to perform socially desired behavior.

The law- and control-based systems that criminology is traditionally concerned with can clearly be associated with the first regulatory type. However, even within regimes based on mandatory rules, regulators can go beyond command and control and target the full set of behavioral determinants to produce compliant behavior. Accordingly, regulatory enforcement can be related to the three basic regulatory strategies known in criminology: (1) *incapacitation and target hardening*, (2) *deterrence*, and (3) *accommodation* (Picciotto 2002). Two definitional settings are required for this relational positioning: First, we need to equate sanctioning and deterrence not only with punitive measures but with the production of incentives that reduce the relative competitiveness of rule breaking (including damage compensations, recall costs, contractual fines, litigation costs, losses of sales, etc.). Second, we need to understand accommodation as not only addressing personal values but including other ways of human capacity building.

Regulatory and criminological scholars from different normative schools attribute different degrees of importance to material and nonmaterial

motivations. Some believe in deterrence only; others believe that accommodation and gentle persuasion (i.e., the promotion of protective factors) work to secure compliance (Ayres and Braithwaite 1992). Contrary to this antithetic pairing, evidence from a wide range of fields – from occupational safety (Scholz and Gray 1990) over standards in nuclear plants (Rees 1994) to tax compliance (Braithwaite 2009) – indicates that successful strategies avoid the dysfunctional effects of pure deterrence, such as defiance and reactance, and the negative effects of pure accommodation and leniency, such as a blurring of standards. Successful strategies are able to simultaneously reduce economic temptations and strengthen bonds to social norms by generating *value correspondence* between regulator and regulatees.

Focusing on tertiary prevention and the reduction of recidivism, Braithwaite (2002) provides a related systematization of regulatory strategies and stresses that they need to be combined and applied in a systematic progression. He distinguishes *restorative justice coaching* (persuasion/counseling) from increasing levels of *deterrence* (warning letters → civil penalties → criminal penalties) and finally from different levels of *incapacitation* (license suspension → license revocation). Accounting for the pros and cons of persuasion as opposed to the various degrees of punishment, he advocates that one should attempt to reintegrate offenders into the rule-abiding society by using transparent and graduated responses to misconduct, with escalating/de-escalating measures contingent on the regulatee's degree of bad/good conduct (*responsive regulation*). According to his *enforcement pyramid*, noncompliance should be met with a clear disapproval of the fact and increasingly punitive measures, but regulators should always start softly by using the cooperative measures of persuasion and counseling aimed at reintegrating offenders into the law-abiding community. This is not to be confused with naïve trust. According to the concept of responsive regulation, the harsher the available ultimate sanctions, the more likely compliance will be achieved through persuasion. The recommendation to regulators would therefore be to “speak softly, while carrying very big sticks” (Ayres

and Braithwaite 1992, p. 40, paraphrasing a well-known quotation from Theodore Roosevelt).

Technically speaking, the responsive regulation approach moves away from an overly simplistic partial perspective according to which one might ostensibly conclude, for instance, that the more controls and sanctions, the higher the actors' inclination to abide by the rules. Instead, responsive regulation represents a holistic approach geared to generate and exploit positive interactions between nonmaterial and material behavioral determinants and, above all, to avoid so-called ironic or perverse effects of sanctions and control, including *self-fulfilling prophecies of distrust* (Luhmann 2000). It can thus be related to the concern with motivation in law and behavioral science. When regulators introduce new measures to steer behavior, be they new rules or new enforcement approaches, a *ceteris paribus* assumption with an exclusive focus on economic incentives is hardly adequate to predict the behavioral impacts. This is due to the fact that the following interactions may occur (cf. Frey 1997):

- Even primarily incentive-oriented regulatory action – be it based on monetary rewards for desired or on sanctions against undesired behavior – may have a positive impact on internal protective factors as well. This will be the case, for instance, if incentives/disincentives and accompanying controls are being appreciated by the individual as a clear affirmation of what is right and wrong in a society. Such desirable synergies of regulatory action have been termed *motivation crowding in*.
- Regulatory change such as tightening of controls and/or an increase of sanctions may reduce the economic temptation to break rules but impair internal protective factors. In such a case, the positive impact on the behavior in question will be lessened, and the desired motivational change could even be reduced to (or below) zero. Such dysfunctional dynamic shifts have been termed *motivation crowding out*.
- Regulatory change aimed at reducing economic temptations might even generate risk factors. When regulatees experience a new regulation as an illegitimate interference with their basic

values and/or freedom of action, they may derive a genuine nonmaterial internal benefit from standing up against the new rule. This reactance makes them even accept an economic disadvantage of rule-breaking (a *negative ethical premium*) in exchange for the satisfaction of asserting their autonomy in the face of what they see as an outrageous interference.

Frey and Jegen (2001, p. 590) describe motivation crowding out as “one of the most important behavioral anomalies in economics, as it suggests the opposite of the most fundamental economic ‘law,’ that raising monetary incentives increases supply.” One would certainly have to integrate reactance into this statement. The *behavioral anomaly* obviously dissolves as soon as one adopts a more realistic and broad utilitarian view instead of maintaining narrow rational choice assumptions. Regulators should realize that regulatory change may cause interconnected impacts and consequently search for strategies that are “smart” in that they avoid dysfunctional effects and, at best, generate synergies. The conception of economic man underlying the change from the famous *get incentives right* to the more adequate *get utilities right* – as subjectively expected by those who are subject to rules – is the key to the understanding of what behavioral economic analysis and the regulatory issue are essentially about (Hirschauer et al. 2012).

Last not least, looking beyond the enforcement of given rules, it should be noted that producing compliant behavior makes only sense if the rule itself makes sense. If a rule is not meaningful in the first place (i.e., if the social costs associated with compliance exceed the social benefits of compliance), then even the most effective production of compliance will not contribute to a positive outcome in the real world. If a rule makes sense, however, adverse social outcomes resulting from malpractice can be conceived as *negative externalities* that are caused by the breaking of rules that had been designed to prevent them in the first place. In this latter case, we can indeed limit our concerns to the question of how society can cost-efficiently make individuals abide by its (presumably social efficient) rules.

Public Choice: The Virginia School

Rosolino A. Candela

Political Theory Project, Department of Political Science, Brown University, Providence, RI, USA

Abstract

Public Choice, broadly defined, is the economic analysis of nonmarket decision-making. My primary focus in this chapter will be on the central importance of the “Virginia School” of

Public Choice, specifically in two aspects. First, Public Choice was central to countering the presumption of market failure among economists, beginning in the 1950s and 1960s. Second, yet less emphasized, is the role in which Public Choice played in analyzing the economics of anarchy, beginning in the 1970s. Although seemingly disconnected, both aspects of the Virginia School are linked by the fundamental question of political economy: Under what institutional conditions can social order emerge unintendedly from the self-interest of individuals? Therefore, in both respects, the Virginia School has been central to the rearticulation of 19th political economy during the twentieth and twenty-first centuries.

Introduction

Public Choice, broadly defined, is the economic analysis of nonmarket decision-making. More specifically, James Buchanan, who cofounded the field of Public Choice with Gordon Tullock, referred to Public Choice as “politics without romance” (Buchanan 1979). Public Choice first emerged as a discipline within the broader tradition of political economy at the Thomas Jefferson Center for Studies in Political Economy at the University of Virginia (UVA), which Buchanan co-founded in 1957 together with G. Warren Nutter. Since then, several other branches of Public Choice have emerged. These include the “Bloomington School” of Vincent and Elinor Ostrom; the “Chicago School” developed by Gary Becker, Sam Peltzman, and George Stigler; and the “Rochester School” of William Riker. To compare and contrast each of these branches of Public Choice, let alone provide a comprehensive survey of the entire field, goes beyond the scope of this entry (see Mitchell 1988 and Mueller 1976).

My primary focus in this chapter will be on the central importance of the “Virginia School” of Public Choice, specifically in two aspects. First, more than any other branch of public choice, its explicit motivation “is the rejection of all of the pillars of the Samuelsonian revolution” (Boettke

and Marciano 2015: 54), which had begun to emphasize the tendency for markets to be a sub-optimal mechanism of resource allocation. By applying the logic of economic decision-making to political settings, Public Choice economists countered the Samuelsonian presumption of market failure by pointing out that governments may also be suboptimal in their attempt to address market failures. Second, yet less emphasized, is the role in which Public Choice played in analyzing the economics of anarchy. Beginning in the 1970s, the Virginia School began to analyze the mechanisms by which institutions can emerge to define and enforce property rights and contractual arrangements without government. This has led to a flowering of theoretical and historical case studies providing evidence of social cooperation without government.

At first glance, these two aspects of the Virginia School seem to be disconnected. However, both the study of government failure and anarchy are flips sides of the same question grounding political economy: Under what *institutional* conditions can social order emerge unintendedly from the self-interest of individuals? Therefore, in both respects, the Virginia School has been central to the rearticulation of 19th political economy during the twentieth and twenty-first centuries. In both the study of government failure and anarchy, the uniqueness of the Virginia School has been its ability to “marry the property-rights, law-and-economics, public-choice, Austrian subjectivist approaches” of economics (Buchanan 2015: 260). For the remainder of this chapter, I will trace out the origins and contributions of the Virginia School to the broader tradition of political economy.

A Brief Overview of the Virginia School

The origins of Public Choice can be traced back to Adam Smith and the classical political economists of the nineteenth century. What all branches of Public Choice, in particular the Virginia School, shared with classical political economy is their comparative analysis of alternative processes of decision-making and their respective results under

alternative institutional arrangements, particularly between market and nonmarket institutional settings. Public Choice, and the Virginia School in particular, bases its analysis of political decision-making on three basic assumptions: (1) rational choice; (2) methodological individualism; and (3) politics as an exchange process.

To say that individuals choose rationally implies simply the following: When an individual faces a set of alternatives, he or she will choose the alternative they expect to give them the greatest satisfaction. In other words, the pursuit of one's rational self-interest implies simply that individuals choose more rather than less of whatever they prefer, or that the individual *strives* to maximize utility. Moreover, Public Choice assumes *behavioral symmetry*, meaning that individuals are utility maximizers in both market and political settings; the only difference between market and political actors is the manner in which utility-maximizing behavior manifests itself. For example, in the marketplace, firm owners strive to maximize monetary profit, but in nonprofit setting, such as politics, there are four groups of decision-makers, each of which are maximizing utility as well. They include voters and interest groups, who want goods and services from elected officials, politicians (i.e., elected officials), who strive to maximize votes and financial support from interest groups and voters, and bureaucrats, who wish to maximize their budgets from elected officials (Simmons 2011: 52).

Unlike in the market place, where individuals express their preference by "voting" with their dollars for different goods sold simultaneously by competing firms, the same individual in politics must vote on a single, bundled policy, which constitutes many different goods, "sold" to them by political officials they've elected. Given the bundled nature of public policy, and its implementation, voters will be rationally ignorant, given the high costs of gathering information about the different "goods" in a policy bundle, which may include defense, health care, import tariffs, etc. Moreover, the bundle nature of public policy also implies that individuals will prefer different "goods" *within the bundle* with different intensities. For example, given the concentrated benefit

from implementing tariffs on imported sugar, domestic sugar producers will no doubt express greater preference for such a policy, in the form of votes as well as campaign contributions to elected officials, unlike the common voter, who will tend to remain relatively ignorant of such a policy. Therefore, the logic of political decision-making will be for vote-maximizing politicians to concentrate benefits on well-organized and well-informed interest groups, which include budget-maximizing bureaucracies, and disperse costs on unorganized and ill-informed voters. Such a political outcome is rational, once we've traced such an outcome back to the choices made by utility-maximizing individuals under a nonmarket setting, where individuals do not bear the full costs and benefits of their decision-making. This brings us to methodological individualism.

By rejecting an organic holistic vision of the state, Public Choice employs methodological individualism, meaning that the outcomes of collective action are traced back to the choices and interactions of rational, utility maximizers. This does not imply that individual preferences can be aggregated into a social welfare function, which the state maximizes on behalf of the electorate. Rather, collective action under a methodologically individualist view will take place if two or more individuals find it mutually beneficial to accomplish certain common purposes jointly with others, rather than separately through bilateral market interactions, an example being the drainage of a mosquito-infested swamp (Buchanan 1964: 219–220). This example reveals that, in the Virginia School, social phenomena are not simply the result of individuals passively responding to constraints.

Unlike in a constrained maximization problem, defined by fixed constraints, Public Choice theorists of the Virginia School direct their analytic attention to *choice among constraints*, where politics is the artifact of an exchange process, whereby individuals strive to agree to mutually beneficial rules that constrain their behavior in a Pareto-optimal manner. The Virginia School political economists therefore take a *constitutional perspective*, which focuses on analyzing "the rules of game" that governs political

interaction. Relevant political choices, according to the study Constitutional Political Economy, are not choices among alternative distributions or allocations of resources within a set of political rules. Rather, it postulates that relevant political choices are among an alternative set of political rules that generate different patterns of distribution and allocation of resources. Constitutional Political Economy is tied to Public Choice, broadly speaking, in two respects. Assuming rational self-interest on the part of political officials, alternative decision-making rules, such as majority rule or unanimity, will generate different policy outcomes within those sets of rules. For example, requiring more than majority rule for road repair will tend to reduce public expenditure on roads, since more people will have to be included in the political exchange. Increasing the number of individuals as a decision-making rule will consequently increase the cost to the beneficiaries of road repair, and, therefore, low costs will be spilled over and dispersed to parties not agreeing with the exchange. Second, political reform cannot occur by changing the “players” within the political game, but only by changing the rules by which the game is played. It is no accident that the study of Public Choice, and the Virginia School, in particular, emerged when the rule level of analysis began to recede to the background of political and economic analysis.

The birth of the Virginia School cannot be understood outside the historical context it inherited. The Samuelsonian revolution changed the tacit presupposition of economists with regard to the government’s role in a market economy, from a “laissez-faire presumption” to a “market failure presumption” (Boettke and Lesson 2015: xiii–xviii). This presumption can best be understood as *epistemological*, rather than political or ideological. Under the laissez-faire presumption, the analytical description of the market economy was complemented by a default presumption to limit government’s role in the marketplace, generally speaking, to the protection of private property and contract enforcement. However, under the market failure presumption, economists assume that the presence of macroeconomic instability, monopoly power, externalities, and public

goods will merit, by default, government correction of the market’s allocative process. The distinction here is not simply a presumption of “more government” or “less government,” but fundamentally a presumption of what knowledge government officials possess to correct market failures. Buchanan best states this distinction as follows:

The classical (Smithean) argument for control (or depoliticization) and the welfare economists’ argument for control (for politicization) are on all fours *only if we presume the existence of the same underlying evaluative standard in the two cases*. To suggest, with the welfare economists, that market failure supports politicization, there must be not only departures from the necessary conditions for efficiency, but also some presumption that political action is informed by a knowledge of what the allocatively efficient solution is, quite apart from the operation of politics itself. By contrast, to suggest, with Adam Smith, that regulatory failure supports market liberalization does not require any presumptive knowledge about what particular outcome is likely to produce maximal value. *There is a categorical epistemological difference between the two comparative exercises, a difference that many modern economists still do not understand*. (emphasis added, Buchanan 1996 [2001]: 292)

Central to this “market failure presumption” and the Samuelsonian paradigm was the presumed existence of an objective social welfare function, which government officials would maximize by delivering an optimal amount of public goods, eliminating monopoly power and externalities, and establishing macroeconomic stability in the economy through aggregate demand management. From this context, Buchanan, Tullock, and the Virginia School established Public Choice, based on the notion of *homo economicus* and politics as an exchange process.

Public Choice and Government Failure

Beginning in the late 1940s and early 1950s, Public Choice began to counter the presumption of market failure by challenging the existence of an objective social welfare function. In his 1949 article, “The Pure Theory of Government Finance: A Suggested Approach,” Buchanan contrasted between an “organismic” theory of

the state and an “individualistic” theory of the state. The basis of this contrast would not only define Buchanan’s intellectual trajectory (Wagner 2017), but also that of Public Choice as well. According to the organismic theory, the state is considered as a single decision-making unit, or “a fiscal brain” as Buchanan puts it, which acts for society as a whole by seeking to maximize “general welfare” or “social utility” (1949: 497). In the individualistic theory of the state, the state embodies no ends other than those of individuals in society, who find it in their self-interest to pursue a certain portion of their wants collectively. The individualistic theory typifies the nature of interaction between individuals and the state as an “exchange” of government services paid out of the economic resources of individuals. The basis of the individualistic theory of the state, and the Public Choice perspective, is an extension of two related aspects from economic theory: (1) based on the incentive structure of an institutional setting, individuals will act according to their own self-interest (i.e., *homo economicus*); and (2) individuals pursue their self-interest by engaging in mutually beneficial exchange. By applying the behavioral postulate of *homo economicus* and the principle of mutually beneficial exchange to political decision-making, Public Choice challenges the main pillars of the Samuelsonian paradigm by arguing threefold: (1) there is no objective welfare function that a benevolent despot maximizes; (2) even if such a social welfare function existed, only individuals choose, not “society” or “the state”; and (3) individuals acting in a market setting or a political setting will pursue their self-interest based on their subjective assessment of costs and benefits (Boettke 2012: 249).

In countering the paradigm of Samuelsonian economics, Public Choice emerged “as a ‘theory of government failure’ that offsets ‘the theory of market failure’ that emerged from theoretical welfare economics” (Buchanan 1983 [2000]: 113). Under market failure theory, perfect competition became the normative benchmark from which the inefficiencies of real-world market outcomes were compared. Any deviations from perfectly competitive equilibrium, such as the presence of public

goods, externalities, monopoly power, or asymmetric information, imply government intervention as a public policy prescription to correct for such market failures. Consistent with the evaluative standard of perfect competition, political actors are presumed to possess perfect information to address market failures. However, this was a categorical epistemological difference in understanding market processes as well as political processes, not only for the Virginia School, but also for economists prior to the mid-twentieth century. Ronald Coase, a pioneer in the field of law and economics, and one of the early faculty members of the Thomas Jefferson Center at the UVA, best articulated this presumption of government failure:

This “novel theory” (novel with Adam Smith) is, of course, that the allocation of resources should be determined by the forces of the market rather than as a result of government decisions. Quite apart from the malallocations which are the result of political pressures, an administrative agency which attempts to perform the function normally carried out by the pricing mechanism operates under two handicaps. First of all, it lacks the precise monetary measure of benefit and cost provided by the market. Second, it cannot, by the nature of things, be in possession of all the relevant information possessed by the managers of every business. . . to say nothing of the preferences of consumers for the various goods and services (Coase 1959: 18).

Rather than view economics in terms of states of equilibrium, the Virginia School has always regarded economics as a science of exchange and the institutions within exchange takes place. By anchoring political choices in price theory and methodological individualism, Buchanan, Tullock, and the Virginia School as a whole were able to turn the presumption of market failure on its head, namely, by marrying the best insights of the property-rights economists, law-and-economics, and Austrian subjectivism. For example, following the subjectivism of Austrian economists Carl Menger, Ludwig von Mises, and F.A. Hayek, Buchanan saw the notion of cost as inherently tied to the act of individual choice and understood a subjective assessment of trade-offs by individuals if it would have any meaning in a theory of decision-making (Buchanan 1969 [1999]; see also Buchanan and

Thirby 1981). Although a seemingly elementary insight into price theory, its public policy implications for market failure theorists are devastating. For example, in the face of externalities, such as pollution, market failure economists would propose, à la Pigou, the use of taxes so that individual polluters would bring the full social costs of polluting into their decision-making. However, returning to the earlier quote by Coase, this presumes that political actors have both the incentives as well as the knowledge to address these market failures in accordance with ideal conditions of general competitive equilibrium. However, under such conditions, such a policy is either possible and redundant, or impossible to set because the institutional conditions presupposed for their establishment either eliminate their necessity or preclude the availability of the knowledge necessary to calculate the correct tax to levy.

In the field of public finance, Buchanan challenged the Samuelsonian orthodoxy in fiscal policy by questioning the incentives that political actors face in balancing budgets, namely by demonstrating the intergenerational transfer of government debt (Buchanan 1958 [1999]). In his 1948 edition of his seminal text *Economics*, Paul Samuelson argued that the “interest on internal debt is paid by Americans to Americans; there is no *direct* loss of goods and services” (Samuelson 1948: 427). In other words, government debt is not a burden because “we owe it to ourselves.” By disregarding the notion of a social welfare function, let alone its maximization, what Public Choice shows is that political actors will only assess costs as subjective trade-offs in the maximization of their own utility functions. Understood this way, politicians will only have the incentive to run ever increasing budget deficits, not to smooth government spending over the business cycle. This is because the economic logic that political officials face in their decision-making is to concentrate benefits among small and well-organized interest groups in their constituency, and disperse costs among the ill-informed masses of the population. Alternatively speaking, if we regard fiscal responsibility as a public good, political actors face a free-rider

problem in the elimination of budget deficits, namely because of the cost of eliminating a spending program will be concentrated on a specific interest group, while the benefits of eliminating fiscal irresponsibility will only be dispersed throughout the population. Given the absence of property rights in a political institutional setting, it only makes political sense that a “tragedy of the fiscal commons” will prevail (see Wagner 2012). Thus, it is the interest of political actors to shift the debt burden to future generations. This fiscal insight, however, has broader public policy implications. Given the logic of political decision-making, government attempts to address alleged market failures, not only in the form of macroeconomic instability, but also in the presence of monopoly, externalities, and public goods, are prone to rent-seeking and regulatory capture for the private benefit of special interest groups, which also include government bureaucracies who benefit from the expansion of the scale and scope of government. As we show in the next section, this general concern regarding the ever increasing size and scope of government due to government failure naturally evolved into a presumption of anarchy in the Virginia School (see Powell and Stringham 2009).

Public Choice and Anarchy

Beginning in the 1970s, Public Choice economists began to analyze the capability of individuals to engage in peaceful social cooperation without government. Although seemingly new and radical, this was an inquiry in political economy dating back to the nineteenth century. Carl Menger proposed this question in his 1883 book, *Investigations into the Method of the Social Sciences*, where he asked the following: “*How can it be that institutions which serve the common welfare and are extremely significant for its development come into being without a common will directed toward establishing them?*” (emphasis original, 1883 [1985]: 146). Due to the civil unrest that emerged during the Vietnam War and the Civil Rights movement, James Buchanan, Gordon Tullock, and Winston Bush undertook a

radical re-examination of alternative institutional arrangements for governing society at Virginia Polytechnic Institute and State University, resulting in the publication of *Explorations in the Theory of Anarchy* (1972) and *Further Explorations in the Theory of Anarchy* (1974). As Winston Bush stated, “[i]t is not surprising that ‘anarchy’ and ‘anarchism’ have reemerged as topics for discussion in the 1960s and the 1970s, as tentacles of government progressively invade private lives and as the alleged objectives of such invasions receded yet further from attainment” (1972 [2005]: 10). However, the early investigations into the prospects of anarchy were generally more pessimistic that they would later become among scholars of the Virginia School. Given the historical context in which they were writing, Buchanan, Bush, and the other contributors regarded anarchism with skepticism. “The anarchists of the 1960s,” according to Buchanan, “were enemies of order, rather than proponents of any alternative organizational structure” (2005: 192). Anarchy, as it was understood in *Explorations in the Theory of Anarchy* and *Further Explorations in the Theory of Anarchy*, referred to a state in society characterized by the absence of law, leading to banditry, violence, and social disorder. The common assumption held by these scholars was an identification of government with governance itself.

Since the 1970s, however, Public Choice scholars have extended the original work on government failure to show in fact that anarchy operates more effectively than previously believed. Applying the same logic developed by the earlier generation of Public Choice economists to develop the theory of government failure, later these scholars simply pushed the theory to its logical conclusion, arguing that governments would not always improve upon conditions of anarchy. The work of Public Choice economist Bruce Benson illustrates this well. For example, Benson has shown historically how international commercial law, known as the Law Merchant, emerged spontaneously in Medieval Europe to facilitate international trade, and operated without government enforcement. Disputes between merchants were settled in private merchant courts, and

these court decisions were accepted by winners and losers because they were backed by the discipline of repeated dealings as well as the threat of ostracism by the merchant community at large (Benson 1989). In *The Enterprise of Law* (1990), Benson also illustrates how the centralization of law enforcement by government in England later crowded out private mechanisms of law enforcement for the purpose of using the legal system to collect revenue. The failure of anarchy to provide a private market for law enforcement can be attributed then to government failure.

Another important publication in the transition from a pessimistic presumption of anarchy to a more optimistic presumption of anarchy was *Anarchy, State and Public Choice* (2005), which was ostensibly written in response to the contributions written in *Explorations in the Theory of Anarchy* and *Further Explorations in the Theory of Anarchy*. From *Anarchy, State and Public Choice*, a burgeoning literature has further developed the economic analysis of anarchy. Whereas the earlier generation of Virginia School economists saw the gains from trade and innovation being limited by the extent to which governments secured property rights and enforced contracts, the empirical challenge of this newer generation was to show that the existence of such potential gains from trade and innovation presented an entrepreneurial profit opportunity for the endogenous formation of norms and rules.

The economic analysis of anarchy as it evolved in the 1990s and 2000s, like the economic analysis of government failure in the 1950s and 1960s, cannot be understood outside the historical context in which such scholarship emerged. Specific events, such as the collapse of communism in Eastern and Central Europe, ethnic and religious fractionalization in the Balkans and the Middle East, and the exportation of liberal democracy to failed and weak states in the developing world, have demonstrated that governance requires the endogenous formation of rules, rather than their imposition by governments exogenously (Coyne 2008). Moreover, the economic analysis of anarchy, just like the theory of government failure that preceded it, emerged to counter the policy

implications of utilizing perfectly competitive equilibrium as a normative benchmark of analyzing markets in the developing world. The standard neoclassical model populated by fully informed and homogenous agents, in which property rights are well-defined and well-enforced, is unreliable to understanding the situation of failed and weak states in the developing world for two reasons. First, governments in the developing world provide poor enforcement of property rights, or are outright predatory. Second, precisely because the situation in failed and weak states is one in which individuals are heterogeneous, have imperfect information, and exhibit high discount rates, collective action problems that may exist under anarchy may prove to be even worse under a dysfunctional government. For example, the Virginia School scholars have looked at Somalia as a case study, analyzing development economic indicators before and after the collapse of the Barre regime in 1991. While it may be the case that Somalia under anarchy remains one of the poorest parts of the world, it does not automatically follow that the re-establishment of government would be an ideal solution for the provision of governance. In Somalia, data on standard indicators of economic development suggests that statelessness has improved Somali development substantially in terms of lower rates of infant mortality, higher life expectancy, and lower percentage of individuals living on less than one dollar per day (See Leeson 2007: 697). Scholars of anarchy in the Virginia School, like their predecessors analyzing government failure, have attempted to overturn the existence of a “Nirvana Fallacy” (Demsetz 1969) by comparing imperfect and real institutional alternatives in history between the existence of anarchy and the state. Such analysis can be traced back not only to the roots of Public Choice broadly defined as the economic analysis of nonmarket decision-making, but also more specifically as the study of the economic role of the state without romance. In both respects, Public Choice, particularly the Virginia School, has progressively brought the central inquiry of political economy back to the foreground of economics in the twentieth and twenty-first centuries.

Conclusion

Given the breadth and development of Public Choice since the 1950s, the author has focused on the intellectual origins and evolution of the Virginia School of Public Choice. The author has highlighted the uniqueness of the Virginia School in developing a theory of government failure to counter the presumption of market failure in economics. Moreover, in developing this presumption of government failure, the author has highlighted that the economic analysis of anarchy has followed logically from the initial skepticism among Public Choice economists to use public policy measures to address market failures. Although seemingly separate enterprises, they are both rooted in comparative institutional analysis and an understanding of the price mechanism as offering the possible approach to understanding the emergence of peaceful social cooperation without government command.

Public Enforcement

Iljoong Kim

Department of Economics, SungKyunKwan University (SKKU), Jongno-Gu, Seoul, South Korea

Abstract

This essay starts with discussions regarding what public enforcement is and why it is necessary. We explain economic rationales under which public enforcement becomes a superior sanctioning mode, in controlling many undesirable acts, to a wide variety of non-public sanctioning counterparts. Nonetheless, given that a large portion of the literature considers the high-cost aspect of public enforcement, the essay emphasizes the importance of lowering administrative costs and overcoming bureaucracy. From a similar perspective, we also examine the combination of public and non-public enforcement as well as the joint use of different modes of public enforcement.

Synonyms

[Law enforcement by government](#)

Definition

Public enforcement (PE) is a sanctioning mode involving a wide variety of government people such as police, prosecutors, and regulators.

Although society can rely on a range of non-public sanctioning modes to control undesirable acts, certain situations occur where economic rationales exist for PE. The social harm from the act, the probability of detection, and the severity of the sanction are critical for its optimality. It is also important to lower administrative costs and to overcome bureaucracy for successful PE.

Introduction

Public enforcement is a sanctioning mode sometimes with the use of physical force, involving a wide variety of people in the government sector such as police, prosecutors, and various regulators. In fact, the phenomenon of public enforcement playing such a predominant role is very recent in human history terms.

Believing that an efficient sanctioning mode varies across different situations, a number of scholars have examined the issue of enforcement for some time under themes such as “system of social control,” “structure of enforcement,” “modalities of regulation,” or “methods of public control” (Ellickson 1973; Shavell 1993; Posner 2011). In particular, since Becker (1968), scholars have paid special attention to public enforcement and have produced numerous articles.

Why Public Enforcement and How Is It Undertaken?

Society relies on a range of nonpublic sanctioning modes to control many undesirable acts. A representative example is “self-help” such as reputation, self-protection, and purchase of insurance (Ehrlich and Becker 1972). Another example is civil litigations associated with torts, contracts, and other private-law doctrines, sometimes called “judicial regulations” (Posner 2011). Society has also developed remedial methods to support these nonpublic sanctioning modes, such as the property rule, the liability rule, or inalienability (Calabresi and Melamed 1972). However, certain situations occur where these private sanctioning

modes do not work or become very inefficient in coping with undesirable actors.

Since Becker and Stigler (1974), Shavell (1984a), and others, it has been well established that at least four economic rationales exist for public enforcement. Public enforcement becomes a superior mode as government is better equipped in gathering information about the production of harm. Also, upon being caught, injurers may have insufficient assets to compensate the victim (i.e., the judgment-proof problem). It is also superior when the potential injurer seldom faces the threat of civil suits and can thus escape liability. Finally, public enforcement should not incur too high administrative costs to secure its superiority.

Given these situations, based on Polinsky and Shavell (2000) and others, let us consider briefly how public enforcers could set the severity of the sanction (s) at an optimal level. A risk-neutral injurer (A) obtains a benefit (b) from an act which can incur social harm (h), with a probability (q). If h occurs, A is caught with a probability (p). p is less than one, reflecting the reality of imperfect enforcement. h differs across acts and is assumed to be fixed in the short run.

The optimality requires that the expected sanction to A , ps , should equal the expected social harm, qh . Since A then performs the act only when b exceeds ps , the optimality condition warrants the social efficiency of the act in question (i.e., the condition whereby b should exceed qh). In other words, A 's private incentive is consistent with that of the social planner. Further, since p is less than one, the optimal level of s is qh divided by p . Thus, the inverse of p plays the role of a multiplier, so that A 's private decision can be internalized appropriately. Note that the optimal level of s should be reduced if A is risk averse. Otherwise, A 's act will be over-deterred because the expected net benefit (i.e., b contracted by qh) is discounted by risk aversion. Finally, noteworthy is that this model is independent of A 's benefit, b . In fact, a model heavily focusing on b inevitably forces public enforcers to focus on the information associated with b that can inherently be more easily fabricated by A , consistently making the arrow of public enforcers land wide on the target of optimal sanctioning.

Additional comments on this simple model might shed beneficial insights, even for more complicated models that were later developed. First, public enforcers, of the three variables in the model, need to have precise information particularly regarding h across different acts, in order for this system to work (p and q are assumed to be fixed at least in the short run, and information on b is unnecessary). Therefore, the aforementioned superiority of government in gathering information about the harm is a core prerequisite for public enforcement.

Second, although the (low) level of p has often been treated as exogenous, public enforcers must maintain a certain level of p ; otherwise, the system will suffer from the ex post equity problem between the detected injurers and those who escaped successfully. Further, a prohibitively high s with a very low p (close to zero) will too easily induce the judgment-proof problem, leading to nullification of public enforcement. More importantly, such a system will hamper the essential (constitutional) principle in enforcement of “marginal deterrence,” which postulates that the severity of sanction should increase proportionally to the harm level. This notion, in fact, was emphasized even in earliest writings such as Bentham’s *Principles* in 1789. For example, if the death penalty or a one million dollar fine is imposed to a driver who hits a pedestrian and causes a slight wound, the driver would have an incentive to run away or even to kill the wounded pedestrian to escape the penalty. Therefore, public enforcers are required to invest in raising p to an acceptable level, which would consume real resources.

Lowering High Costs of Public Enforcement and Overcoming Bureaucracy

As theoretical inquiries have shown, public enforcement certainly offers an advantage under many circumstances. Nonetheless, as with many other government operations, it incurs generally high cost. If the assumptions about the government as the benevolent and omniscient planner are

released, the cost further increases. A large portion of the literature considers this cost aspect of public enforcement.

Firstly, scholars realized that, while public enforcement is needed for a certain number of undesirable acts, for various reasons, such acts cannot be efficiently controlled by it alone. For example, the marginal information cost increases with respect to the degree of enforcement sophistication. In fact, such recognitions motivated scholars to examine the allocation of public enforcement resources, even from the early stage of research. It is perhaps in this context that research on the combination of public and non-public enforcement captured their attention. In retrospect, these early studies were meaningful contributions, particularly in the sense that the researchers were developing more hands-on normative theory built on positive observations.

Consider the case of using traffic signals to maintain order on public roads. Enforcement by police in terms of whether drivers violate them can be done reasonably easily. However, police cannot assign a tailor-made speed limit that reflects each driver’s value of time, level of urgency, driving skill, etc. The limit is uniformly enforced (e.g., 100 km/h on highways and 30 km/h in downtown areas). If a driver mistakenly hits another car while driving over the limit and causes harm, liability is imposed on top of issuing a ticket (i.e., “per se negligent”). However, the opposite rule (i.e., “compliance defense”) does not hold. That is, even if the injurer is driving under the limit, liability is not automatically exempted.

This joint use of public enforcement and liability is used in most jurisdictions. Shavell (1984b) attempted the first theorization to draw its efficiency implication. He highlighted the imperfect nature of public enforcement (e.g., enforcing the speed limit) due to imperfect information particularly about different magnitudes of harm. Also, the insufficient precaution when using liability alone was emphasized. Thus, a popular proposition followed that it is socially cheaper to employ regulation and liability jointly, with a lower regulatory standard than if liability were not used. Later, the role of liability to

ameliorate the high costs of public enforcement, primarily in terms of reducing information costs, was further confirmed. Also, the role of public enforcement to support liability was sometimes underlined instead. Overall, these studies were endeavors in search of efficient public enforcement, given its high costs (Kolstad et al. 1990; De Geest and Dari-Mattiacci 2007; Bhole and Wagner 2008).

Scholars subsequently applied these theoretical studies to broad arenas, ranging from product safety to transportation, hazards, environment, health, etc. La Porta et al. (2006) provided an exemplary inquiry. The authors demonstrated that the proper use of civil liability standards together with public enforcement is necessary for the successful operation of securities markets. Meanwhile, extensions were made to explore the joint use of different modes of public enforcement, such as that of administrative penalties and criminal punishment (Garoupa and Gomez-Pomar 2004; Bowles et al. 2008). Given that such joint use is ubiquitous across countries, this approach is differentiated from the earlier dichotomous-choice models. Furthermore, research on the combined criminal sanctions of fines and imprisonment was launched already in the 1980s (Polinsky and Shavell 1984). A major implication is that the use of imprisonment, the highest-cost sanction, should be confined to cases where the insufficient-asset problem or the need to incapacitate offenders prevails.

Finally, a brief but significant caveat deserves mention. Although overall features of actual public enforcement are roughly consistent with the theories, substantial discrepancy routinely occurs, i.e., “bad equilibrium,” primarily due to the public enforcer’s incentives which differ from the public-interest mindsets that ordinary citizens would expect them to have (Becker and Stigler 1974). Public enforcement can be characterized as being dominated by “entrepreneurial competition,” wherein bureaucrats pursue their subjective goals such as wealth, promotion, and discretion (Breton and Wintrobe 1982). Numerous researchers have already examined public enforcement from this perspective. Nonetheless, in summary, it should be emphasized that the details of public

enforcement must be steadily scrutinized through these critical lenses in order to facilitate a change in such bad equilibria. Also, in attempting to further lower high costs, incentive-compatible rules must be implemented that require much more use of “pricing” in the allocation of enforcement resources.

Public Goods

Definition

A public good is a good that simultaneously features both nonexcludability and nonrivalry in consumption.

Delimitation and Examples

A pure public good is a good that simultaneously features both nonexcludability and nonrivalry in consumption. Nonexcludability implies that excluding individuals from making use of the good is prohibitively costly, such that all individuals can benefit from the provision of the good. Nonrivalry means that the consumption of the good by one individual does not reduce the consumption possibilities of other individuals. Classic examples include national defense or a lighthouse. In contrast, a private good is characterized by both excludability and rivalry in consumption. For example, if an apple is consumed by one individual no other individual can make use of the apple. In addition, excluding other individuals from the benefits of the apple is associated with only minor costs. There are also goods that show rivalry in consumption but nonexcludability. Such goods are denoted commons

and are exemplified by fish in a given area. While it is difficult and costly to exclude individuals from fishing, every fish caught by one person can no longer be caught by any other individual and may endanger the sustainability of the stock of fish. Finally, pure public goods have to be distinguished from club goods. Club goods are characterized by nonrivalry in consumption and the possibility of exclusion. Broadcasting can be regarded as a club good, because watching the program does not influence the option for others to do the same while exclusion is possible through the use of scrambling.

Theory

From an economic point of view, the property that the consumption of the public good by one individual does not infringe on the consumption benefits of other individuals leads to a first question: how is the socially optimal supply of a pure public good determined? Moreover, given nonrivalry and nonexcludability, it is also interesting whether markets or voluntary contributions by individuals can implement the optimal supply of the public good. The basic problem may best be illustrated by a simple example resembling the prisoners' dilemma.

Suppose there are two individuals, A and B, who both hold an endowment that generates private utility equal to one. Each individual decides once whether or not to use the endowment to provide one unit of a public good. Due to the nonrivalry of the public good, both individuals gain from the provision of one unit of the public good by either of the individuals. Suppose that the utility derived per unit of the public good equals 0.75 for each individual. Table 1 summarizes the possible choices and resulting utility levels, where the first (second) entry refers to individual A's (B's) utility level.

Public Goods, Table 1 Actions and payoffs in a simple public-good game

Individual A/Individual B	Don't supply	Supply
Don't supply	1;1	1.75;0.75
Supply	0.75;1.75	1.5;1.5

The outcome that maximizes the sum of utilities is the one in which both individuals supply one unit of the public good (in which case the joint payoff equals three). The costs for each unit supplied are equal to one while the joint payoff is given by 1.5 ($0.75 + 0.75$). However, if the individuals A and B decide independently, each of them fares better by not supplying one unit of the public good given any decision by the other individual. The supply of one unit of the public good only yields a private benefit of 0.75 for each individual and is not sufficient to balance the utility cost equal to one. As a result, the equilibrium in strictly dominant strategies is that neither A nor B supplies a unit of the public good; consequently both end up with a utility level of one. This outcome is Pareto inferior to the optimal solution.

The example illustrates two ideas regarding public goods: (1) To decide on the socially optimal level of supply of the public good, the costs of supplying an additional unit should be compared to the sum of gains achieved by all individuals through the additional supply (due to the property of nonrivalry). (2) Without cooperative decision-making, the voluntary supply of the public good may not yield the optimal outcome.

More generally, the seminal condition that characterizes the Pareto-efficient supply of a public good was first established by Samuelson (1954, 1955). For any two private goods, a Pareto-efficient allocation is achieved when the marginal rates of substitution between the two goods (i.e., the rates at which individuals are willing to exchange the two goods without a change in utility) are equalized for all individuals and, in addition, are equal to the marginal rate of transformation (i.e., the rate at which the two goods can be exchanged according to the production possibility set). In contrast, the optimal allocation regarding a public good and a private one requires that the sum of the marginal rates of substitution over all individuals is equal to the marginal rate of transformation. As in the example above, increasing the supply of the public good is socially desirable as long as the marginal costs (i.e., the marginal rate of transformation) are weakly less than the sum of the gains enjoyed by all

individuals (i.e., the sum of the marginal rates of substitution).

An important contribution examining the theory of the noncooperative provision of public goods is provided by Bergstrom et al. (1986). They confirm that public goods are underprovided and establish that a redistribution of wealth among individuals will change the amount of the public good supplied only if it changes the set of individuals actually contributing to the public good. Furthermore, additional supply of the public good by the state (and financed by taxes) will at least partly (if not fully) be offset by reductions in private contributions.

A cooperative provision of public goods may be attained under some circumstances, especially when the group considered is small. For example, a Lindahl equilibrium constitutes an allocation resulting from bargaining which results in a Pareto-efficient supply of the public good with individual-specific contributions based on each individual's valuation of the public good (Lindahl 1919). However, it must be acknowledged that individuals might have an incentive to misrepresent their preferences. The later literature related to the topic of cooperative public good provision has been greatly influenced by the work on collective action by Olsen (1965).

An alternative to the private provision of public goods is the provision by the state that can collect contributions by force in the form of taxes. In this case, if only distortionary taxes can be used to raise revenue, the additional costs from these distortions should be taken into account when deciding about the optimal level of the public good (see, e.g., Atkinson and Stern 1974). An even more fundamental problem arises in the case with asymmetric information about individuals' preferences. If individual payments are to be based on the stated preferences for the public good, individuals might understate their willingness to pay. Otherwise they might overstate it if they know that the burden of financing the additional supply will be shared by the society as a whole. Clarke (1971) and Groves (1973) present a mechanism which leads to a truthful statement about preferences. The amount of the public good may also be determined by majority voting

instead of by a benevolent government, a scenario for which Bowen (1943) offers an early analysis (Bergstrom and Goodman 1973 provide an empirical investigation).

The theory of public good provision based on standard preferences has been complemented by predictions derived from alternative specifications for individual preferences. For example, in order to better understand the sizable contributions to charities, nonstandard motives such as impure altruism may be considered. In the case of impure altruism, individuals obtain utility by increasing their contribution not only from a higher total level of the public good but also from having a higher individual contribution since these create a so-called warm glow (Andreoni 1989, 1990). The predictions that follow from frameworks enriched in such a way are often more intuitive and more in line with empirical observations, such as the result that government contributions to charity will only incompletely crowd out private donations.

Experiments

For decades, the so-called public-good game has been a workhorse for experimental economists interested in social dilemmas and their potential resolution through institutions (e.g., Ledyard 1995). Classically, individuals in groups of n subjects simultaneously determine the split of their symmetric endowments between a public account and a private one, where the return from the public account per subject is determined by the product of the marginal per capita return ($MPCR$) and the sum of contributions and $0 < MPCR < 1 < MPCR * n$ applies. This is the so-called linear public good game and has a unique Nash equilibrium in which no subject (with standard preferences) contributes. The experimental finding that subjects contribute on average 40–60% of their endowment to the public good in the one-shot version or in the first round of the repeated variant of the game is in striking contrast to the prediction based on standard preferences. However, the initially high contribution rates, which decline over time, are consistent with

the idea that there are many conditionally cooperative subjects who are willing to contribute more when they expect others to contribute, although they do not match an increase in contributions by the others in full (e.g., Croson 2007; Fischbacher et al. 2001). Turning to institutions that remedy free-riding incentives, allowing participants to punish peers based on their contributions seems effective (although not necessarily efficient when punishment costs are taken into account). Intuitively, costly peer punishment is on average predominantly chosen by subjects with above-average contributions and addressed at subjects with below-average contributions. Such a mechanism seems to be associated with not only higher overall contributions but in the case of low costs of punishment and/or a long time horizon with real efficiency gains (e.g., Chaudhuri 2011). Interestingly, there is experimental evidence that the possibility of peer punishment attracts subjects when they can migrate between a regime with the possibility to sanction and one without and that sanctioning institutions emerge endogenously (e.g., Gürer et al. 2006; Kosfeld et al. 2009). Other means to improve contributions to the public good include communication and ostracism (e.g., Chaudhuri 2011; Maier-Rigaud et al. 2010).

Applications

The theory of public goods is relevant to a number of applications in the field of law and economics. First, the private enforcement of norms, for example, by assigning punishment points to peers in experimental settings (as just described) or by ostracizing and shaming offenders in the field may become subject to free-rider incentives, as the deterrence benefit is diffused (e.g., Posner 1997). Relatedly, consider the case of unobservable private precautions against crime. When a household increases investments, this lowers the expected return for the potential offenders, decreasing the involvement of thieves. The benefit accrues to all households equally, whereas the full costs are borne by the household in question. This implies that decentrally determined private precautions

against crime fall short of what is optimal for the group of households (e.g., Shavell 1991). In another realm, it is often argued that the knowledge created by innovative activity is nonrival and may present difficulties regarding excludability. Patents ensure excludability for some time, thereby incentivizing the creation of knowledge while limiting the extent of the use of the knowledge. Accordingly, there is a discussion of the relative merits of different instruments in this context (e.g., Shavell and van Ypersele 2001). In addition, the divergence of private marginal benefits and social marginal benefits that commonly arises with public goods may also induce socially inefficient private incentives to proceed to trial. Court decisions may be socially valuable by creating public information about plaintiffs or precedents, aspects which usually do not feature prominently in the private trade-off (e.g., Hua and Spier 2005; Shavell 1999).

Public Interest

Michael Hantke-Domas

Centre for Water Law, Policy and Science,
University of Dundee, Scotland, United Kingdom
Third Environment Court, Valdivia, Chile

Abstract

The public interest is a concept that can be traced back to the late XVIII century. Ever since the concept has been used to refer to a goal to be obtained by actions of governments and public officials alike. Such view has been strongly contested by important economic schools such as Public Choice and the Chicago School of Regulation. Based on neoclassical economics, they contend the altruism needed to deliver in the public interest, as public officials pursue their own interest and regulations are captured to benefit regulated industries but recognizes the existence of equilibria that might balance the interests at stake (like Pareto or Kaldor-Hicks criteria). In contrast, the law is more optimistic when using public interest either to proceduralize collective interest or for courts adjudication. Even more, public interest serves as justification for government intervention in economic affairs. In the last decades, the promotion of integrity and prevention of corruption have tackled self-interest of public officials, leaving space for the public interest to be pursued by governments and public officials.

Definition

Public interest is the motivation of public officials in exercising their functions to achieve the common good of the collective, by improving democracy and social and economic welfare.

Introduction

Abraham Lincoln in his Gettysburg address (1863) coined a famous phrase defining

democracy as a “government of the people, by the people, for the people.” The idea that governments – or States, in continental European tradition – must serve the people is an expectation common to many people in modern history.

Modern States are inspired in the principles of the French Revolution that changed the Old Regime to a new social organization based on the values of liberty, equality, and fraternity. The State as a moral entity is – or should be – the guarantor of such values. The State has grown to become one of the most important institutions in many aspects of societies. Indeed, meanwhile in the nineteenth century, government expenditure amounted to 10% of GDP, and by 1996 it amounted to 45% in developed OECD countries (see Middleton 1996; Tanzi and Schuknecht 2000).

The “common good” – or the general welfare – is an important ideal for governments, as they must act in pursuance of public interest. However, what is the substance or content of such ideal?

John Rawls, in his book *A Theory of Justice* (1971), does not treat public interest as a common good but rather delineates a corresponding ethical ideal that is “justice as fairness” (Weisbrod and Benjamin 1978).

“For us the primary subject of justice is the basic structure of society, or more exactly, the way in which the major social institutions [political constitution and the principal economic and social arrangements] distribute fundamental rights and duties and determine the division of advantages from social cooperation...the major institutions [for example, the legal protection of freedom of thought and liberty of conscience, competitive markets, private property in the means of production, and the monogamous family] define men’s rights and duties and influence their life prospects, what they can expect to be and how well they can hope to do.” (p. 7)

Public interest or justice as fairness hinges upon an assessment made in the “initial situation” where an interpretation is made of the moment and the problem of choice it poses, and an agreement is entered into on a set of principles (Rawls 1971). These principles illuminate what public interest is as they serve as guidance for the initial

position, in the sense that (a) each person has rights equal “to the most extensive basic liberty compatible with a similar liberty of others” (p. 60) and “social and economic inequalities are to be arranged so that they both (a) reasonably expect to be to everyone’s advantage, and (b) attached to positions and offices open to all” (p. 60). Restating Rawls’ proposal, public interest or justice as fairness might refer to equal rights and fair access.

Economists have different takes, which range from equating public interest to general welfare to those that see no benefit to anyone except public officials. Lawyers feel more comfortable with the concept, and the concept of public interest is widely used with less skepticism.

Not surprisingly the concept of public interest has attracted criticism, as some think that it is too broad to mean something specific (Lewis 2006). Notwithstanding, the concept remains important, probably because it is an analytic tool or a heuristic device present in normative public administration theory, economic regulation, administrative law, and judicial procedures. It is also important in governmental and professional standards of practice (Lewis 2006). Furthermore, it is of relevance for law, as interests are objects of protection by constitutions and laws, and adjudicated by the judiciary (Schmidt-Assmann 2003). Public interest is also important in economics as market failures – and the role of the State to correct them – find in public interest a rationale for economic regulation.

Despite the controversy, what remains the same is the existence of a space where citizens can get together to, for example, entrust their protection either from foreign aggression or for getting medical assistance.

As public interest can be interpreted from a variety of disciplines, I will devote the rest of the entry to reviewing the discussions from the standpoints of economics and law.

Public Interest and Economics

The concept of public interest holds the attention of economists in at least two different areas. First,

it is a criterion used in collective choice, an area of economics that cares about the relationships between the preferences of individuals and the choices made by the government (Brown and Jackson 1998). Second, it is used for State regulation of economic activities when markets fail.

In liberal democracies, citizens select their representatives (e.g., members of parliaments or presidents) to make decisions and choices on their behalf. For economists, the aggregation of all individual preferences produces multiple combinations that are efficient to adopt by governments. However, this aggregation does not specify how societies formulate and express collective value judgments (Brown and Jackson 1998).

This is the point where disagreements start to appear, as ethical issues arise regarding collective choice rules (is the rule ethically acceptable?). Economists have argued over the idea of the rational, disinterested, and benevolent public official, which altruistically takes office for the good of the whole community.

Public choice scholars blow off the foundations of the commonly accepted idea that government officials pursue the interests of the whole community. They sustain that human beings act on a rational, self-interested, and utility maximizing basis (Mueller 1989) meaning that government officials act pursuing their own interest rather than promoting the general welfare.

Anthony Downs (1957), in *An Economic Theory of Democracy*, sustained that human beings are selfish. This is simply the application of a tenet of neoclassical economic theory of consumers. As individuals maximize their own utility, Downs could not fathom why government officials should depart from such truism to be altruists devoting their work to enhance the general welfare. If everyone is selfish, then government officials should be the same. Downs also studied political parties and concluded that they were mere vehicles to foster private interests (Lewin 1991).

In the same line as Downs, Buchanan and Tullock in *The Calculus of Consent* (1962) sustained that politics is an exchange between parties that aim to maximize individual interest. Common good was discarded as naive, since

public interest could only mean the satisfaction of many individual desires, facilitated by political activity (Lewin 1991).

Later, Gordon Tullock elaborated on government officials and concluded that an expression of their self-interest was the expansion of public sector irrespective of costs. According to Tullock, bureaucrats wanted to enhance their position either by increasing their own salaries, esteem, or influence. Bureaucrats disregarded the intentions of legislature – similar to public interest – as they wanted to foster their own private interests (Lewin 1991).

Public interest, viewed from public choice theory, is simply the aggregation of individual interests. Paradoxically, it is impossible, under mild conditions, to aggregate individual interests as Kenneth Arrow (1951) demonstrated in his *general possibility theorem*. In short, it is impossible to create a social order of preferences based on individual interests that meet certain criteria: unrestricted domain, non-dictatorship, Pareto efficiency, and independence from irrelevant alternatives (Sola 2004).

Leif Lewin (1991) adds that such impossibility is reinforced by the prisoner's dilemma, which shows that self-centered individuals driven by their own individual preferences usually end up worse off not better off from a collective point of view.

Even if it were possible to aggregate individual preferences, economics only presents a narrow frame of reference, as it does not include in its analysis different social and political values inherent to our democracies, which usually are part of the legal basis for the existence of the State, represented in their constitutions (Feintuck 2010). One clear example is the environment, as it has legal recognition providing for regulation that stretches beyond economic analysis, for example, the precautionary principle that allows governments to adopt decisions despite the existence of incomplete scientific data to warrant them, in order to protect the environment (Feintuck 2010).

Economic regulation is connected to collective choice as both are motivated by public and/or private interests. Government decisions are

present in the regulatory process, from ascertaining the need for State intervention to its implementation. Thus, the collective choice discussion is part of economic regulation. The assessment of whether a market fails or not and the decisions to correct externalities, to complete information, to promote competition, to solve principal-agent problems, and to provide public goods are all governed by collective choice.

Economic regulation studies have shown that its implementation might not satisfy general welfare, as regulation in itself might fail (for reviews, see Hägg 1997; Hantke-Domas 2003). The Chicago Theory of Regulation, originated in the works of George Stigler (1971) and further developed by Sam Peltzman (1976) and Gary Becker (1983), holds that regulation is captured by industry and consequently is designed and operated for its benefit. Richard Posner (1974) added that empirical evidence showed the poor performance of the regulatory process usually benefited influence groups. In addition, regulation encourages rent-seeking behavior because interested parties are willing to invest in order to yield favorable decision-making by agencies or courts (Harnay and Marciano 2011).

Equally, economists have shown mechanisms allowing to correct market failures through the market without the need for governmental regulation, i.e., self-centered agents still maximize welfare even in case of market failures such as externalities or monopolies, for example, Coase's theorem regarding property rights and externalities or Demsetz's contestable markets showing that even if competition *within* the market is not possible, it still is possible to motivate competition *for* the market (Hägg 1997).

Institutional economics has shown that regulatory institutions (i.e., governments) can replace or assist private bargaining in the presence of externalities or risks born by groups facing high transaction costs or asymmetry of information endured by consumers prior to transactions. This insight might be associated with public interest, but it is not contradictory with public choice or the Chicago theory of regulation. Indeed, regulatory institutions might well be the result of pressure groups or the correction of a market failure (Hägg 1997).

Agency theory sustains that economic regulation fails as information is asymmetrical between regulators and regulated industry; hence, the latter can extract economic rents in the regulatory process. This phenomenon leads to agency capture. In other words, correction of market failures – aiming at enhancing general welfare – may not be possible as regulated industries drag out the regulatory process (Laffont and Tirole 1993). Again, this insight does not trump the public choice of the Chicago theory of regulation, but sheds light on the complexities of economic regulation, leaving space for public interests to be a driving force of regulation (Hägg 1997).

The discussion on collective choice shows that public decisions cannot satisfy every individual interest and the quest for public interest might be more complex than assuming that governments will promote it seamlessly. Notwithstanding, it is possible to find efficiency in cases of State intervention, despite the limitations annotated. Pareto criterion might be satisfied if at least one person is better off and none of the rest are worse off. Even in the former case, public interest decisions might be efficient if the well off can compensate the worse off, using the Kaldor-Hicks criterion (Coleman 1980).

Public Interest and Law

Public interest is ubiquitous within the realm of law. It proceduralizes collective interests, and courts adjudicate disputes to achieve justice. Public officials assess their actions against the interests of the whole community in implementing public policy by means of the law.

Traditionally, the law has used the concept of public interest as justification for government intervention in economic affairs. Black's Law Dictionary (2004) defines it as "The general welfare of the public that warrants recognition and protection" or "Something in which the public as a whole has a stake; esp., an interest that justifies governmental regulation."

In its regulatory justification, public interest originally appeared in the work of Lord Mathew

Hale, *The Portibus Maris* (1787), inspiring two important decisions, one in England (*Allnutt v. Inglis*) and one in the United States (*Munn v. Illinois*). In essence, Lord Hale sustained that private businesses become *juris publici* if they were licensed or chartered by the King to act as a monopoly and those services were available to the public (Hantke-Domas 2003). The importance of the concept lies in the fact that some economic activities were in the interest of the public, and correspondingly it was necessary to balance expectations with the economic activity to obtain mutual benefit (Craig 1991).

The law embraces the concept of public interest in many ways besides being a warrant for governmental regulation. The UK Enterprise Act (2002) introduced a "public interest test" in cases of takeovers and mergers, by which the Secretary of State may intervene in the latter if interests of the public are involved as, for example, with issues of national security, media quality, plurality and standards, and financial stability ("Takeovers," n.d.). The UK Public Interest Disclosure Act (1998) bears a test that grants protection to whistle-blowing employees if the matter brought to light is in the public interest. Another important UK law is the Freedom of Information Act 2000 that provides for access to government-held information only if the public interest in disclosing it outweighs the public interest in not disclosing it. In these three laws, public interest is liberally used either to justify by the government a ban on a merger or to withhold or publicize information.

Civil service is another area where public interest is present ("Public Interest in UK Courts" 2011). In the United Kingdom, Lord Nolan's 7 Principles of Public Life are part of the remit of the Committee on Standards in Public Life advising the British government. For example, "selflessness" principle affirms, "Holders of public office should act solely in terms of the public interest." In Spain, its constitution (Section 103.1) obliges its civil service ("*administración pública*") to work for "general interests."

British courts may deal with public interest in different opportunities as defined by the Public Interest in UK Courts Project (2014). First, the law refers expressly to the concept, as in the case

of the English Freedom of Information Act 2000. Second, it refers to legal proceedings brought by the Attorney General in the “public interest.” Third, the courts may invoke the concept to justify new developments in the law. Fourth, public interest immunity may be argued in court by the Crown to withhold documents from parties when such disclosure may be contrary to the public interest. Fifth, European Union law and the law of the European Convention on Human Rights recognize rights of European citizens but that these rights can be limited in the public interest in cases of national security, public health, and the prevention of crime.

Public officials’ decisions in England are subject to judicial review regarding lawful exercise of their statutory powers. Public interest may be argued by courts to extend this review to non-statutory decisions. In continental Europe administrative law holds public officials accountable for the same reason, but with a comparative more developed corpus of law known as contentious administrative.

In Spain concepts such as “just economic and social order” or “quality of life” are written in her constitution and are part of the common good; hence “. . . public interest happens when the aim that must be served by a political or administrative organisation on its entirety, can only be achieved by that entirety” (Parejo 2003). More precisely, the general interest is fused together with the aims of the State. In the Spanish Constitution general interest refers to the protection of legal interests belonging to the community, a safeguard duty that must be assumed by the State as it is in charge of managing the common interest (Parejo 2003).

From a German perspective, the idea of common good is equally present, and for Prof. Eberhard Schmidt-Assmann (2003) it is the guidance for Parliament, public officials, and judges, but to be defended as well by private entities, interest groups, and individuals. Public interest strives to ensure the general interest. Both concepts are not interchangeable, but since public interest is promoted by the community, it tends to become general interest. Private interests are not opposed to general ones and in their evolution

blend with the general interest. Public interest is not predefined and static, but it evolves throughout the administrative process. The administration – or government – is conceived as a structure representing multiple public interests. For Prof. Schmidt-Assmann general welfare is equivalent to common good, and public interest is the feasible fulfillment of common interests by means of the law. “The determination of what is general welfare is a matter depending above all on positive law, which normally offers for its achievement procedures and material criteria” (2003, p. 167). This proceduralization of public interest should be understood under the light of fundamental rights and the rules regarding the State function. Common good is the government-guiding ideal to act in favor of the community, and democracy is better served if common good is actively pursued.

The use of the concept of public interest as a heuristic tool is present in the United Kingdom and in Spain and Germany, but in Spain and Germany, it is a legal obligation to be followed by the State, whereas in the United Kingdom it guides a limited set of situations.

This simple overview of different uses of public interest in the law shows that institutions are always inspired to serve the community and public officials are bound to pursue the public interest. Economists, at least some of them, reject any possibility that a public official – or anyone – may act in any way but for his or her own interest; hence the public interest might be an excuse for advancement by protecting the interests of groups. Law and economics clash for being on the one hand idealist (law) whereas on the other hand pessimistic (economics), but the power of law guarantees that public officials will be restrained on their self-interest. The law carries penalties that cannot be defined as idealistic, such as jail terms or hefty fines.

Consistent with the Public Choice Theory and the Chicago Theory of Regulation that dispute the existence of a benevolent government always searching for maximum social welfare, in the last decades the promotion of integrity and the prevention of corruption in the public space have increased. Although studies and policies on

corruption do not focus on public interest, they tackle self-interest of public officials. The matter has taken a prominent position on the agenda of international organizations with the adoption of the United Nations Convention against Corruption (2003). Indeed, important efforts to oblige States to implement regulations to curb the phenomenon preceded the UN Convention, as the OECD Convention on Combating Bribery of Foreign Public Officials in International Business Transactions (1999) or the Organization of American States Inter-American Convention against Corruption (1996). National legislation has gathered pace (e.g., UK's Bribery Act 2010, US Foreign Corrupt Practices Act).

Under the light of integrity legislation, corruption emerges when a public official obtains a private gain or status from office. Indeed, corruption is defined as “the abuse of public office for private gain” (World Bank 1997). A more comprehensive definition is given by Robert Klitgaard (1988) “behaviour which deviates from the formal duties of a public role because of private regarding (personal, close family, private clique) pecuniary or status gains; or violates rules against the exercise of certain types of private regarding behaviour.”

Behind the international effort to curtail corruption is the belief – and evidence – that corruption distorts prices. Inefficient markets with covert and upward redistribution of wealth within a society increase costs and reduce investment and produce a decline in society's moral and ethics (Senior 2006). Corruption can be petty or grand, and even there are some authors that affirm that in some societies, corruption helps failed States to run properly.

Using Robert Klitgaard's (1988) corruption equation (corruption equals monopoly power plus discretion by officials minus accountability), if public officials are rational, then public interest – as opposed to personal interest – should be pursued by them if the expected gain by the corruption is less than the penalty of being caught and prosecuted. This conclusion leaves the possibility that public interest can be a motivation for public officials when corruption is not present.

Public Investments: Broadband

Nicola Matteucci
Department of Economics and Social Sciences, Marche Polytechnic University, Ancona, Italy

Abstract

After a long phase of liberalizations, privatizations, and deregulation, in telecommunications the policy pendulum has moved in the opposite direction, and the State is back in many countries. By mid-2000s, the deployment of first-generation broadband communications had reached high levels of diffusion and, thanks to market-friendly regulation, market competition has generally led consumer prices to decline. However, marked dynamics did not ensure universal service (especially in rural areas), nor the continuous upgrade of the networks, with the migration to higher capacity NGAN – two requisites increasingly demanded by downstream market developments (e-Services, cloud computing, IoT). This entry reconstructs the main market, Government and (cohesion) policy failures occurring in the sector, and the responses so far experimented in the EU, in an international perspective. In particular, it illustrates its State aid control system and analyzes the current trade-off that the new industrial policy is posing to the policy-maker in a liberalized sector.

Liberalization, Privatization, and Market-Friendly Regulation

Since the 1980s (in the USA) and then the 1990s in Europe, there was a mounting consensus toward market liberalization and privatization of public companies (see entries on ► [State-Owned Enterprises](#)) – especially those active in network industries and utilities. Telecommunications were one of the sectors most heavily interested, starting with the famous AT&T breakup in the USA. According to the received wisdom, the privatization of this sector should have brought the largest societal benefits – at least in terms of retail prices (Newbery 2004); a main motivation was that technological developments would have reduced the competitive bottlenecks that had been justifying public monopolies and heavy old-style regulation (such as rate of return); then, market liberalization would have spurred pro-competitive dynamics, be able to progressively deregulate the concerned sectors, and move from *ex ante* (regulation) to *ex post* (antitrust) norms. Such a received wisdom does inform the current European Regulatory Framework for electronic communications (ex Directive 2002/21/EC and its further amendments) (see entry on ► [Telecommunications](#) – if any has been planned for the European Regulatory Framework).

As a matter of fact, in parallel with the paradigm change unfolding at the political and institutional levels, a technological revolution was also occurring, characterized by the advent of digital technologies for signal coding, transmission, and reception, that would have been deeply transforming the economics of network communication industries – particularly that of television and telecommunications. In particular, thanks to digital technologies and growing equipment standardization, the legacy communication networks (*in primis*, copper, and cable TV ones) have been transformed in a multipurpose infrastructure and able to carry a converging array of distinct services: voice telephony, video content, and data. As a consequence of this technological breakthrough, telecommunication networks have progressively converged with traditional audiovisual media, and new hybrid communication platforms

and services have been introduced, such as IPTV (Internet protocol TV) (Matteucci 2016). Concerning the market consequences of the technological and institutional transformation, it is conventionally believed that the outcomes differ by market (services and countries), although presenting some broad regularities. In wireless services (*in primis*, mobile phones, where digital technology caused a relevant relaxation of the existing spectrum constraints), liberalization and privatization were unquestionably pro-competitive and elicited a unprecedented surge of new investments by entrants in both developed and developing countries, with the best results achieved where spectrum management was more effective. In fixed telephony services, the impact of the institutional transformation remained less clear-cut, due to the natural monopoly features still persisting along the distribution network (local loop), the varying effectiveness of the regulatory and policy mix, and the multifaceted implications of digital technologies. For example, Bacchiocchi et al. (2011) find that for EU-15 countries in voice services, regulation played a larger impact in driving down prices than privatization. On a similar vein, Florio (2004), after studying with cost-benefit analysis tools the famous British Telecom privatization in the UK, reconsiders the received wisdom and concludes that effective regulation may be much more important for the overall welfare than ownership regimes (public versus private) per se and that the latter had a small effect on the long-term dynamics of consumer prices and productivity – at least in the UK. Indeed, this evidence recalls what standard microeconomic theory predicts that an unregulated monopolist (or dominant firm) sets profit-maximizing prices, higher than competitive ones: hence, regulation may be the crucial aspect to look at.

In today's Internet economy, where consumer's usage is increasingly multipurpose and hybrid and requests higher bandwidth capacity, broadband services stand as the main reference product for the telecommunication industry and the policy-makers, replacing the older emphasis on voice services – despite the fact that no formal universal service provision currently covers the

first, differently from the second, according to the existing European Regulatory Framework. In first-generation broadband (conventionally classified as those services offering from basic to premium data transmission rates, respectively, from 2 to 20 Mbps in downloading, and epitomized by ADSL technologies), we have now accumulated a sufficient evidence on the relation between institutional setting and industry performance, especially for EU countries. Here, liberalization together with wholesale access regulation brought about a higher degree of static competition that generally resulted in lower consumer prices. In turn, a favorable retail price dynamics – prevalent in non-concentrated markets – translated into higher take-up: for example, Distaso et al. (2006) found that, in EU-14, lower local loop unbundling prices (henceforth, LLU, the most important type of wholesale access regulation) encouraged the take-up of broadband subscriptions, even though, on the side of the generation of new investment, the detected effects were generally negative (Cambini and Jiang 2009). In the EU, the widespread adoption of the “ladder of investment” regulatory model (henceforth LOI, setting access levels and terms in a way to progressively incentivize entrants to move from service-based to infrastructural-based competition) is believed by its proponents to have contributed to rapidly create competitive retail markets while hopefully stimulating gradual investment strategies by new entrants aimed at building alternative networks (Caves 2014). However, among the encountered drawbacks, wholesale access regulation and LOI could not cater for providing adequate stimuli to rapid network rollout, differently from what achieved with infrastructural competition, where the latter has been available (mostly between DSL copper and cable networks) (Briglauer et al. 2014).

Another fundamental stylized fact in the industry has been that, after liberalizations and privatizations, competition (both service and infrastructural) and private investment for rolling out digital networks first and foremost unfolded in urban areas, while less populated (rural) and socioeconomically disadvantaged areas across

the EU were left behind, because of the higher network deployment costs and of the insufficient revenues characterizing these territories: these conditions typically configure cases of market failures (a situation when an output or activity yields net social returns higher than private ones, so that its market production is suboptimal) and/or problems of social and territorial cohesion (the existence of large GDP differences and resource unbalances between citizens and between regions). In this case, regulation cannot help so much, since even the facilities of incumbent operators (those having significant market power, henceforth SMP) are frequently unavailable or insufficient in these laggard areas, and no universal service provision is in place for broadband services in the EU.

As a consequence, rural and marginal areas accumulated a substantial gap – both concerning the timing and the quality of the communication services offered and subscribed. In particular, in 2013 (the deadline for reaching the first infrastructural objective of the Digital Agenda for Europe, henceforth DAE – EC 2010), the broadband coverage of the EU homes was nearly completed when considered in nominal terms and including all the potential networks (wireless and wired, fixed and mobile) of the first generation; however, the coverage was sensibly lower, on average, if only the more performing fixed technologies (xDSL, cable, and the fixed wireless WiMax) are taken into account: nominally, the latter was at 97.2%, but in real terms, it was often substantially inferior (depending on country and legacy network characteristics). However, the gap of rural areas was still relevant: in fact, in the same year, the nominal fixed coverage of the EU rural areas was lagging at 89.8% of the population (79.9% in 2012) (data from Digital Agenda Scoreboard 2014). Then, if one considers the NGAN achievements (next-generation access networks, including at that time broadband technologies such as VDSL, Cable DOCSIS 3.0, and FTTP), figures were much more disappointing, with fast broadband (ensuring transmission rate >30 Mbps in downloading) covering on average only 62% of the EU homes, but again dropping to only 18.1% in rural areas (with the coverage mostly

attributable to VDSL deployments, involving the incremental upgrade of legacy copper-based networks with segments of fiber optic).

For these reasons, in the current phase of the sector, where a timely rollout of new access infrastructure assumes a paramount societal importance (especially for the wired ultrafast networks, which however involve the highest sunk costs for cabling the terminal link), the policy pendulum is shifting from old-type wholesale access regulation (LLU and LOI) to new models (incentive based and geographically differentiated) and, increasingly, to active industrial policies. The latter, involving an original role for investment with public money, is especially needed if one wants to foster the deployment of wired ultrafast networks to comply with the stated targets and deadlines of the DAE that envisage an ubiquitous and fast-increasing connectivity capacity of the territories as a way to enhance the market competitiveness and socioeconomic growth of the EU society.

The State Comes Back in Telecommunications

Industrial policies aimed at solving the digital divide started to be experienced with first-generation broadband, both in Europe and elsewhere, before igniting a hot economic policy debate with second generation (NGAN). Since 2003, a certain number of small-scale (regional or municipal) State aid (henceforth, SA) measures supporting network deployments had been authorized by the EU Commission and mainly financed with European structural and investment funds or national finances: these measures gradually unfolded across countries as soon as the market diffusion path of broadband services (supply-side coverage and demand-side subscriptions) was progressing and encountering the first difficulties and failures, in relation to the different country sector's maturity (the first measure approved was the Cumbria project, in the UK, EC 2003). These policies acquired momentum in coincidence with the US subprime mortgage financial crisis and the following worldwide macroeconomic

turbulences. In the EU, the first noticeable initiative came out in 2008: the European Economy Recovery Act (EC 2008) loudly announced the introduction of specific measures and funds (roughly EUR 1 billion) earmarked for solving the digital divide affecting rural areas, focusing on the supply-side (investment in infrastructure). Similar and sometimes more ambitious initiatives were adopted by other industrialized countries, along a clear "interventionist" industrial policy agenda. In the USA, in 2009, the extensive budget of the American Recovery and Reinvestment Act included a sum of \$7.2 billion for grants and loans targeting broadband unserved and underserved areas (LaRose et al. 2014); this Act had a clear protectionist flavor, arriving to mandate also a sort of "Buy American" condition for funding, that provoked strong opposition among NAFTA partners (Canada). Other developed countries, including Australia and New Zealand – famous for their usually orthodox neoliberal policy agendas – introduced similarly ambitious plans of public intervention; then, the countries experiencing the highest public support were Japan and South Korea, two recognized worldwide ICT (Information and Communication Technology) leaders. Finally, active industrial policies for broadband were also enacted in BRICS and developing countries – with mixed characteristics and results (for Latin America, Galperin et al. 2013).

In the EU, the awareness of the policy-maker about the real extent of the infrastructural digital divide grew slowly, in parallel with the improvements of the surveying methodologies and available statistics. As a matter of facts, several original initiatives of country territorial mapping began to show that the network coverage gaps were numerous, spotty and very granular, and far from being limited to marginal rural areas – as an uncritical "market failure" rationale had let to assume. On the contrary, in some member states like Italy, historically characterized by dispersed models of urbanization and business location, coverage gaps and service disruptions happened to be very frequent also in strategic socioeconomic areas (export-oriented industrial districts and leading touristic locations), besides being present at the

edges of metropolitan and other urban areas (Matteucci 2014).

At the European level, the draft of the 2009 Broadband Guidelines (EC 2009; updated by the 2013 version, EC 2013) and the DAE (EC 2010) marked a radical step in elaborating a less rhetoric and more pragmatic approach, with respect to the earlier volitive but rather unrealistic agendas for Information and Communication Technologies (henceforth ICT) and Research and Development (R&D) support – from the Lisbon strategy in 2000 to the i2010 action plan in 2005. In particular, the Broadband Guidelines and DAE first paid a special attention to the worrying sluggishness showed by the NGAN market transition in Europe, with respect to the reference areas (US and, above all, the Asian leaders). As a consequence, in this period, some EU member states started to frame systemic and more ambitious nationwide broadband plans, designed to solve the digital divide with mixed policies, financed by a variety of funds and instruments (including public-private partnerships). Finally, in 2015, acknowledging the continuing relevance of these policy priorities, the Commission confirmed the orientation of its policy issuing another “Investment Plan for Europe” (also called “Juncker Plan,” EC 2014a), aimed to stimulate the EU economy with an initial budget of EUR 315 billion devoted to new investment – including NGAN networks; then, in late 2016, the Commission President announced that the European Fund for Strategic Investments (EFSI) (to be employed for the Investment plan) would be doubled by 2022.

The more interventionist policy phase that began at the end of the 2000s was motivated by a series of reasons – both structural and short term. A main one reappraises the traditional macroeconomic benefits of countercyclical fiscal policies (typically advocated by neo-Keynesians), after years of massive consensus on the neoliberal rhetoric and the EU “austerity” economic policy orientation, increasingly put under pressure after the 2008’s financial crisis (Schmidt and Thatcher 2013). Then, more micro-founded explanations acknowledge the specific positive impact of broadband investment on driving innovation, GDP growth, productivity, and competitiveness

(Analysys Mason, Tech4i2 Ltd 2013) – an impact that is proved to be sizable, yielding estimates for the demand multiplier within the range 1.2–1.5. The micro-founded dynamics at work are several. Besides increasing directly the GDP through public expenditures, broadband networks, as many ICT, are “general purpose technologies,” thereby possessing key valuable characteristics enhancing their socioeconomic impact. First, broadband infrastructure is particularly strategic since it channels and exchange increasing amounts of codified information and knowledge that, being public goods and involving positive externalities, are a primary source of innovation and economic growth. Second, broadband investment both spurs large complementary expenditures in other goods and services in the downstream economy. Third, broadband services are highly pervasive, and they enable further innovation and productivity gains in the using sectors, also due to the powerful network externalities and coordination dynamics (of the type “chicken egg”) unfolding with downstream ICT and not-ICT sectors.

At the same time, investment in broadband networks creates its own demand and market (as often most types of infrastructure do, in a “Say’s law” vein); for this, infrastructural investment in a free market economy may well experience coordination failures and holdup behavior by risk-adverse network operators. As a matter of fact, in the post-liberalization phase, the generalized drop in the investment rate experienced in the sector can be interpreted as driven by a rational strategy of privatized fixed network incumbents (now subject to the stock markets dividend constraint): they first aim to avoid cannibalization between NGAN and existing services and, second, opt for incremental and less risky investment paths (e.g., using cheaper FTTC architectures, instead of FTTH ones) to migrate to the new NGAN paradigm. Hence, in network sectors severe market, failures can occur, leading to service under provision and delays contrary to the public interest, however expressed. As a main example, in the current process of digitalization of the public administration (Seri et al. 2014), no forced migration (sunset dates) to digital services like e-Government, e-Health, or e-Participation can be reasonably mandated by

public authorities until all the population had been serviced with adequate broadband access to the Internet. Similarly, promising market developments such as cloud computing and the Internet of Things (IoT) require ubiquitous and constantly upgraded broadband capacity, but this frontier can be severely retarded – or even compromised – by the extent of the old and new types of infrastructural digital divide.

Indeed, for the EU to compromise on reducing the digital divide while not interfering with the outcome of the post-liberalization phase has proved much more difficult than elsewhere, due to the constitutional status of the general prohibition of SA, ex Art. 107(1) TFEU, and its stringent exceptions. At the end, the target of completing the coverage of broadband, although not submitted to a formal provision of universal service under the current Regulatory Framework, was codified as two distinct infrastructural targets of the DAE (EC 2010): to complete the coverage of the EU population (1) with first-generation services by 2013 and (2) with second-generation ones

(NGAN) by 2020. These policy targets can be achieved through generous market incentives (various types of subsidies) and active policy-making; the latter, for some member states, initiated a new challenging season of direct public ownership of the built infrastructure.

EU State Aid Control for Broadband

The current version (2013) of the Broadband Guidelines (henceforth Guidelines) represents the *summa* of the relevant EU policy-making, detailing all the admissible forms of public intervention in the sector (“vertical” SA). Acknowledging that liberalization and privatization profoundly reshaped the telecom market, the Commission first illustrates (EC 2013: Artt. 9–54) the main principles and instruments that any measure involving public money has to follow, to comply with EU competition norms. Basically, there are three main instruments for public financial intervention (see Table 1), according to

Public Investments: Broadband, Table 1 Public support for broadband networks: instruments available in the EU

Instrument	EU founding norm (s)	Goal(s)	Main criterion of scrutiny	Example case
State aid	Art. 107-9 TFEU	Prohibition of any unlawful form of SA, subject to predefined exceptions	Use of State resources, economic selective advantage potentially distorting competition and affecting internal market trade	See the List of the Commission’s decisions (source)
Market economy investor principle	Art. 345 TFEU	Equal treatment between private and public regimes of property ownership and entrepreneurship	Public financial support to an undertaking paid under normal market conditions	Case C 53/06-NL <i>Citynet Amsterdam-Investment (FttH) network</i>
Service of general economic interest	Article 106 (2) TFEU, the “Altmark case” jurisprudence, and “SGEI package”	Guaranteed supply of a SGEI	Imposition of public service obligations in return of specific compensation	Case N 331/08-F <i>THD Hauts-de-Seine</i>
Other administrative and regulatory measures	Regulatory Framework, SA case law, Directive 2014/61/CE	Achieve better market transparency and coordination and investment costs savings	To provide more information, transparency, open access to and efficient construction of network infrastructure	National legislation and regulation implementing the Directive 2014/61/CE

the Treaty on the Functioning of the European Union (TFEU, EU 2012) and the associated hard and soft law norms: (1) the SA norms, (2) the application of the Market Economy Investor Principle (henceforth, MEIP), and (3) the imposition of the special regime of Service of General Economic Interest (SGEI). Further supporting initiatives may concern instruments not falling within the meaning of SA, such as administrative and regulatory measures aimed at facilitating market transparency and coordination. A main example is the “Cost Reduction” Directive (n. 2014/61/CE, EU 2014), due to be implemented by the beginning of 2016, that foresees four main pillars of normative harmonization and promotion of best practices: (1) mandating reuse of existing physical infrastructure to avoid inefficient duplication, on behalf of market entrants; (2) enforcing coordination and transparency of planned civil works, catering for efficient construction; (3) enabling faster, simpler, and more transparent concession of administrative permits; and (4) modernizing norms applicable to new buildings, to be equipped with NGAN-ready facilities.

MEIP and the SGEI are the residual cases: while MEIP concerns public intervention carried out “at market terms” (in commercially profitable areas), SGEI *de facto* regards not profitable areas (“white areas”; see *infra*). Both have been used rather infrequently, due to the application complexities and the potential institutional inconsistencies and normative loopholes involved. Basically, the MEIP case follows the (now somehow neglected) principle of equal treatment between private of public property ownership and entrepreneurship and involves the direct or indirect attribution of public capital (or other tool) to an undertaking under circumstances which mirror normal market conditions (replicating the case of a standard private investor), thereby not qualifying as SA under Art 107 TFEU. The SGEI case, in turn, requires to demonstrate that existing private operators cannot offer in the near-future adequate broadband coverage in a universal way, thereby excluding a portion of the population. Under this prerequisite, an undertaking may be entrusted with the operation of an appropriately defined SGEI, receiving in return a public service

compensation. However, the accompanying conditions are quite demanding, since they are aimed at excluding any possible market interference with existing operators: for example, the motivation of inadequate digital connectivity for businesses in the targeted area would not suffice nor would be possible to entrust the SGEI broadband undertaking with retail operations. In other terms, SGEI feasibility in this sector needs to be limited to the network construction and the supply of wholesale access services through the public offer of the built passive infrastructure, neutrally open (EC 2013, Art. 21–25), whenever such an offer has been demonstrated as being unavailable from private operators. It follows that the practical feasibility of setting a SGEI nowadays is severely limited in any sector that underwent a massive liberalization process, like in the case of telecom and broadband; equally, as it is now, it is very difficult to use the SGEI instrument to relaunch the paradigm of the public company, where this has been privatized.

In essence, the SA norms (see entry ► [State Aids and Subsidies](#)) are the default system of public intervention – also for broadband networks. Art. 107(1) TFEU states a general prohibition of any unlawful form of SA, subject to predefined exceptions (ex Art. 107(2) and (3)), aimed at safeguarding the normal functioning of the internal market. The latter goal is also targeted by the sector liberalization process, and in this sense, the Guidelines match the general SA norms with the principles of the Regulatory Framework, setting binding requisites for efficient and not-distorting state intervention. Accordingly, any measure financed with public money must be preceded by a detailed mapping of the territory, aimed at distinguishing three types of areas: “black,” where infrastructural competition between at least two network operators is present; “gray,” where the service is provided by a unique network; and “white,” where no service is available, now or in the foreseeable future (3 years). Potentially, public intervention is admissible in white areas, while it becomes more difficult to authorize in gray ones and normally is not admitted in black areas (except for ultrafast NGA networks (offering at least 100 Mbps speeds), where the 2013 Guidelines

opened a possibility upon proving the performance “step change” with respect to existing fast NGAN, EC 2013; Artt. 82–85). Mapping of the territory must be conducted at the national level through public consultations with telecom operators, and, once the measure is authorized, any public fund needs to be granted on the basis of open, transparent, and competitive procedures, where bidding operators cannot be discriminated on the basis of the solutions employed (“technological neutrality” principle). Then, once built, the publicly owned or the private infrastructure that got the subsidy (both arrangements are possible) is subject to a reinforced wholesale access regime – independently of the SMP qualification of the winner – and network operations must be monitored for a certain period, to avoid overcompensation (“claw back” clause on the extra profits).

Over time, the Commission’s practice on broadband has evolved and adopted a “more stringent economic approach,” aimed at enhancing its market-friendliness (in line with the 2005 State Aid Action Plan and continuing with the 2012 State Aid Modernization Initiative). This also implied a growing complexity of the relevant soft law that the Commission has somehow tried to streamline by pushing forward the convergence with other “horizontal” SA norms, for example, the recent inclusion of the easier cases (involving only broadband “white” areas) in the General Block Exemption Regulation or the solution of the previous loopholes contained in the 2007–2013 Regional Aid Guidelines, which had provided a more generous authorization pathway.

Since 2003, a large number of SA cases have been analyzed by the EU Commission: as of July 2016, 148 decisions (mostly positive) have been finalized, with a growing presence of country-wide measures (national plans) for NGAN deployment, involving higher budgets; the latter fact is attributable to the larger deployment costs involved in second-generation broadband – mostly, civil engineering works for digging and laying passive infrastructure along the access network (such as ducts, wires and antennas), arriving to account for 70–80% of the total investment

costs. For the largest EU member states (the “big 5”), the representative budget of the most recently authorized national NGAN plans ranges from EUR 2 to 4 billion. On overall, the received wisdom predicates that the net balance of the Commission’s activity is positive: for example, Chirico and Gaál (2014) notice that only a tiny minority of its numerous decisions was appealed.

As a matter of fact, the net balance of the SA activity is multifaceted and much more complex to gauge – even sticking to strict economic considerations. First, economic approaches used in antitrust theory and practice remain prevalently static, so that they miss to consider alternatives of public intervention that may score higher when examined in a truly dynamic setting. Sometimes, even some SA pro-competitive principles (such as that of technological neutrality) can yield unintended effects: while the first version of the Guidelines was inspired by a truly “driving” conception of SA policy (Gómez-Barroso and Feijóo 2012), there are good reasons to believe that the current *de facto* policy assimilation between wireline and wireless NGAN (adopted since EC 2013) can give incentive to less ambitious rollout plans and networks. Second, EU competition law continues to present cases of institutional conflict and normative loophole with other domains – *in primis* with regional and urban policies – and their possibly diverging objectives of social and territorial cohesion (Colomb and Santinha 2014). Third, while the standard Commission’s scrutiny is based on *ex ante* evaluation, there is a real scarcity of evidence and literature on *ex post* evaluation of the implemented measures, which in turn is aggravated by the enduring lack of statistical evidence surrounding the sector’s operations and the heterogeneous member states’ institutional performance – especially at the disaggregated territorial level. Indeed, some broadband SA measures (e.g., EC 2014b) have been encountering severe implementation retards and even problems of institutional capacity that led to a perverse mix of market and Government failures, delaying a prompt achievement of the intended goals (especially, from a cohesion point of view).

Conclusion and Future Directions

To sum up, taking into account the worldwide trend toward higher State intervention on the market and active industrial policy, and their stringent trade consequences (including cases of “beggar-thy-neighbor” policies), it is difficult to predict whether the delicate policy equilibrium so far achieved in SA practice for liberalized network sectors in EU can be firmly maintained in the future – especially in the post-Brexit era. In particular, SA policy could be affected by much stronger pressures and conflicts from member states than before. Moving to a larger picture, in the most pessimistic scenario, due to the constitutional nature of the SA norms, the potential imbalances arising from its application could even arrive to damage the social and institutional cohesion of the EU.

Public-Private Partnerships

Luciano Greco

Department of Economics and Management and CRIEP, University of Padua, Padua, Italy

Definition

Public-private partnerships (PPPs) are organizational forms involving public and private institutions and aiming at the provision of assets, goods, or services that, to a large extent, are relevant in terms of public interest. Alternatively, the same tasks (e.g., construction, operation, maintenance, financing) can be pursued by full-fledged public organizations. The nature of tasks and involved institutions (e.g., for-profit firms, nongovernmental organizations (NGOs), governmental agencies) and the constraints shaping interactions among partners (e.g., contract or information incompleteness) determine different effects as regards the distribution of risks and payoffs among partners and allocative efficiency.

Economics and Institutions

Several concepts of PPPs have been introduced by practitioners and academics. A comprehensive perspective about PPPs can be found in the management literature. Kivleniece and Quélin (2012) define “*public-private ties [...] as any long-term collaborative relationships between one or more private actors and public bodies that combine public sector management or oversight with a private partner's resources and competences for a direct provision of a public good or service.*” In such a rather extensive definition, we may include

a quite large array of institutional arrangements and activities, such as procurement of public infrastructures, collaborations to face societal challenges (e.g., poverty or disease eradication in developing countries), or research-driven joint ventures (Perkmann and Schildt 2015).

In line with the purpose of this essay, we focus on a narrower concept of PPPs as “*an agreement by which the government contracts a private company [or a consortium of firms] to build or improve infrastructure works and to subsequently maintain [and operate] them for an extended period of time [...] in exchange for a stream of revenues during the life of the contract*” (Engel et al. 2014, p. 2). The motivation is twofold. First, the theoretical (particularly, contract theory) literature on PPPs has primarily focused on the optimal design of incentive schemes and on the assessment of costs and benefits of *outsourcing* of important phases of public investment projects. However, the bulk of findings of these contributions can be extended to non-infrastructure PPPs. Second, the most common and recurrent use of PPP concept among practitioners is related to public infrastructures (several initiatives of public institutions in different countries are going to change this: e.g., the EU Commission has recently introduced the concept of *research public-private partnerships* which are joint ventures between public and private institutions to pursue common interest tasks related to large investments in research).

In the public debate, PPPs are often confused with privatizations. In both cases, the government may transfer public assets and activities to private institutions (possibly, for-profit firms) who are then in charge of running them. Nevertheless, two differences between such organizational forms are crucial. First, privatized assets and activities are not (anymore) part of government-specific tasks, while PPP infrastructures and services are (still) part of them. For example, a prison or a barrack continues to be essential facilities of law-and-order or defense governmental policies, even though these are managed by a PPP agreement (instead of a governmental agency). On the contrary, a privatized firm or building serves almost exclusively private purposes (e.g., profit

maximization). In many cases, government continues to play a supervisory role on privatized firms that, on a normative point of view, is not very different with respect to that on other firms in the same sector (this is quite clear in the case of competitive markets, but the same argument holds also for regulated sectors, where governmental authorities play just a market-failure-correction role). Second, privatizations are intended to be forever (unless major political changes foster *renationalization*), while PPPs feature (long but) finished terms, whereby assets and activities are transferred back to government at the end of contracts.

The previous argument has important policy implications. Consider that the government outsources to private institutions activities featuring a strong public interest (e.g., construction and operation of a hospital in countries where healthcare is publicly provided). Independent of the specific organizational setting, such an arrangement is a PPP. Indeed, outsourcing does not divest government of its role, nor it diminishes its responsibilities as regards final outcomes. For example, in the case of healthcare PPPs, any pitfall in the functioning of a hospital implies legal, economic, and political responsibilities for the governmental authority in charge of healthcare provision.

Practitioners' View

PPPs – as above defined – are a well-established practice to construct and operate public infrastructures in several countries (Bezançon 2005; Engel et al. 2014). Practitioners from public institutions and private business have pointed out three channels by which PPPs may improve social welfare, as compared to traditional, government-led frameworks:

1. *Efficiency gains* may derive from enhanced management of tasks – e.g., design, construction, and operation – and risks (many contributions in economics and management literatures emphasize innovation as an autonomous source of dynamic efficiency gains; for the purpose of this essay, we classify it among efficiency gains from enhanced task management).

2. The government may be able to attract and channel private financing into initiatives of public interest, thus relieving the public finance (i.e., *financial leverage*).
3. Government infrastructure policies are affected by perverse political incentives (e.g., investments in “white elephants,” procrastination of maintenance expenditures, expenditure political cycles) that may be corrected by the involvement of private partners (i.e., *market discipline*).

The international experience has shown that such benefits are not systematically delivered by PPPs (Engel et al. 2014; Saussier 2015). Also, in the last 30 years, these organizational forms have been characterized by growing financial and institutional complexity. For these reasons, many countries have introduced public oversight mechanisms. A central task of the latter is the *ex ante* assessment of the balance between costs and benefits (i.e., the so-called value for money) of PPPs, as compared to traditional public organization (Burger and Hawkesworth 2011).

In the last 20 years, different strands of academic literature have investigated the conditions under which the abovementioned benefits are likely to materialize.

Contract Theory Literature

As argued, complexity has become a distinguishing feature of PPPs. For example, the most prominent form of such arrangements, the *project financing* technique, puts a *project company* – also called *special purpose vehicle* or *consortium* – at the center of “a web of contracts aimed at distributing tasks, risks, costs, and revenues among all (private) partners” (Greco 2015). This explains why, in the last decades, contract theory contributions have been quite useful to elicit the main drivers of potential benefits of PPPs.

The standard analytical framework to assess the role and the features of PPPs is based on a *sequential moral hazard* problem (Hart 2003; Martimort and Pouyet 2008; Iossa and Martimort 2015). In this essay, we abstract from issues related to the *selection* of firms, and we focus

only on the post-contractual problems that are typical of long-term interactions like PPPs. In the simplest case, the public project cycle can be represented by two sequential tasks: in the first phase, a public infrastructure (e.g., a highway) has to be built; in the second phase, the infrastructure has to be operated and maintained to provide services (e.g., freight and passenger transportation). The social value of the public infrastructure is determined by the investment effort, which is implemented in the building phase, and by the management effort, which is implemented in the operation phase.

As a matter of fact, governments need external resources and competences to build and, in many cases, to manage public infrastructures. In this context, the main policy issue is whether it is better to outsource the two tasks to different agents (i.e., a building firm, in the first phase, and an operating-and-maintenance firm, in the second phase) or to a single agent (i.e., a consortium of firms that are specialized in different tasks). In the literature, the first setting – based on sequential contracting – is often called *unbundling* of tasks, as opposed to the alternative *bundling* of tasks. The latter represents, in a very stylized fashion, the basic contractual structure of PPPs.

A Basic Model

To grasp the essential issues of the choice between bundling and unbundling – which explains efficiency gains from PPPs – let us consider a very simplistic model. The quality of public infrastructures is almost always multidimensional; however, for our purposes, we consider the monetary value of the capacity of the infrastructure to satisfy end users and, possibly, to produce positive externalities on the whole society. Thus, the investment in infrastructure (say, highway) quality can be either high – i.e., $I = 1$ – or low, i.e., $I = 0$, and generates a gross social benefit $B = \tilde{B} + bI$, where $\tilde{B}$ is the exogenous (possibly, random) benefit generated by a minimum-quality highway and $b > 0$ is the marginal benefit of increasing the quality of the highway.

During the management phase, the operation and maintenance costs are $C = \tilde{C} - \delta I$, where $\tilde{C}$ is the exogenous (possibly, random) cost

component and δ is the marginal impact (or externality) of the first-phase investment on operation-and-maintenance costs. In most contract theory models on PPPs, the latter plays a crucial role: $\delta > 0$ implies that the first-phase investment is also beneficial in terms of second-phase infrastructure management; such an impact is negative when $\delta < 0$. A couple of examples may clarify this point: investments in technologies for touchless tolling improve the service quality of a new (or newly refurbished) highway but also reduce operation costs (i.e., labor costs), hence $\delta > 0$; conversely, investments to increase the number of lanes of a highway reduce congestion and, thus, increase the service quality but also maintenance costs during the operation phase, i.e., $\delta < 0$. For the sake of simplicity, we abstract from investments and managerial efforts that are typically implemented in the second phase to improve the social value of services provided by the infrastructure.

The *first best optimal outcome* is obtained by choosing $I = 1$ if and only if $b + \delta > 1$ – this result derives by the maximization of the social welfare: $B - I - C = \tilde{B} - \tilde{C} + (b + \delta - 1)I$. In the following, we assume that this condition is met; hence, investing in quality is always optimal from the point of view of the whole society. A benevolent government could attain the first best optimal outcome in a world where contracting with firms to outsource tasks is not affected by any significant informational or contractual imperfection. More technically, information is symmetric – i.e., investments are fully observable – and contracts are complete, i.e., investments can be verified by a court without any cost. In such a “wonderful world,” the choice between bundling and unbundling is immaterial. Any contractual scheme can be used to reach the first best. On the contrary, the choice between PPPs and sequential contracting becomes relevant when outsourcing is affected by substantial informational or contractual imperfections.

Asymmetric Information and Incentive Design

If the government cannot observe the first-phase investment of the builder (i.e., a building firm, under unbundling, or a consortium, under

bundling), neither it can infer it by the observation of B or C (because of the noise created by the exogenous random components $\tilde{B}$ and $\tilde{C}$), a classic moral hazard problem arises. In the absence of any incentive mechanism, the builder has no interest to invest in infrastructure quality. However, the government can design contracts to provide (monetary) incentives to the builder.

Under unbundled contracting, the government contracts with a building firm, in the first place, and then with another firm for operation-and-maintenance tasks. In our simplified setting, there is no moral hazard problem for operation and management. Thus, the second-stage contract is optimally a cost-plus one, $T_o = C$. In turn, the operator earns a zero profit and does not face any operation risk. As regards the building phase, the government can design an incentive payment scheme that is based on observable variables, $T_b(B) = T + tB$, where T is the fixed-price component of the payment to the builder and t is the marginal reward for each unit of extra benefits generated by the infrastructure. The government (correctly) anticipates the reaction of the builder, that is, to invest in quality if and only if $tb > 1$ – i.e., the building firm maximizes its profit: $T - I = T + t\tilde{B} + (tb - 1)I$. Thus, the government can control the decision of the builder by regulating the power of incentives: for $t > \underline{t}_u = \frac{1}{b}$, the builder invests.

Under bundled contracting, the government outsources both tasks to a single consortium of firms. The payment function is now $T_p(B, C) = T + t(B - C)$. Also in this case, the government anticipates that the consortium invests in high quality if and only if $t(b + \delta) > 1$ – i.e., the consortium maximizes its profit: $T - I - C = T + t(\tilde{B} - \tilde{C}) + [t(b + \delta) - 1 + \delta]I$. Again, the government can control the decision to invest of the consortium by a suitable power of incentives: for $t > \underline{t}_p = \frac{1 - \delta}{b + \delta}$, the consortium invests.

Let us remark that the minimum power of incentives to induce investment in infrastructure quality is different with respect to what we have in the unbundling case. In particular, *the power of incentives has to be stronger (respectively, weaker) under unbundling than under bundling*

if $\delta > 0$ (respectively, $\delta < 0$). The previous statement follows by the comparison of $\underline{t}_u$ and $\underline{t}_p$. This difference is irrelevant as far as increasing the power of incentives, i.e., t , is costless, which is the case when moral hazard is the only constraint that affects contracting between government and firms. In turn, both contractual forms afford the first best optimal outcome, and again the choice between bundling and unbundling is immaterial.

In the real world, facing higher-power incentives usually involves additional costs for the agents. For example, *risk-averse* firms require a risk premium (i.e., larger expected returns) to accept riskier contracts (i.e., larger t). In turn, to provide appropriate incentives to firms, the government has also to accept to pay larger expected transfers. A similar effect is determined by *limited liability* (or wealth) constraints faced by firms, which introduce lower bounds to government payments. By the previous arguments, we have:

Proposition 1 *Under asymmetric information and costly incentives, the government prefers bundling over unbundling (or the reverse) if and only if $\delta > 0$ (or $\delta < 0$).*

The basic idea is that the internalization of the externality between first-phase investment and second-phase operation costs reinforces (or weakens) contractual incentives if the externality is positive (or negative). A first policy implication of this literature is that *the enhanced management of synergic tasks is a crucial driver of efficiency gains from PPPs, because of information and financial frictions in the economy*.

Incomplete Contracts, Incentives, and Property Rights

In many real-world situations, observable variables – such as the quality of a hospital or a prison – cannot be assessed with a sufficient degree of precision to be verified by a court at negligible costs (Hart 2003). These quite common situations are characterized by incomplete contracts.

Incomplete contracting has dramatic impacts on the functioning of (alternative) contractual

schemes between government and firms. In particular, a *holdup* problem arises: in the terms of our model, the government is unable to commit to reward investments on the basis of observed (but unverifiable) infrastructure quality; firms rationally anticipate this outcome and do not invest.

Assuming that the ownership of the public infrastructure belongs to the government, the outcome of unbundling and bundling is equivalent to what would happen in the asymmetric information model (that we considered in the last section), when the only contract that the government can sign is such that $t = 0$. Thus, we have:

Proposition 2 *Under incomplete contracts and government ownership, the government prefers bundling over unbundling if and only if $\delta > 1$; otherwise, the two contractual schemes determine the same outcome.*

Contract incompleteness destroys the capacity of government to design (monetary) incentives for firms. In this situation, PPPs may improve social welfare if the intrinsic incentive underlying bundling is sufficiently strong (see Proposition 2).

In this framework, another important driver of incentives is the *distribution of rights* between government and partners (Bennett and Iossa 2006). To clarify this point, let us consider a specific case. If the public infrastructure is a building for (government) offices, it may clearly have alternative uses such that the quality of the infrastructure can be (fully) rewarded on the private market (e.g., a building for private offices). In this case, awarding ownership over such infrastructure to the builder reinforces its incentives to invest in quality. Indeed, once the infrastructure is built and its (high) quality observable, if the government does not pay to reward such quality, the private firm owning the infrastructure can renegotiate the terms of the contract with the government and sell the building on the private market. Anticipating such a situation, the builder invests in quality.

Four remarks are in order. First, the result with private ownership is the opposite with respect to the case of government ownership where, as above discussed, the builder has no incentive to

invest. Thus, the distribution of rights is a (rough) tool to regulate the power of builder's incentives.

Second, the main driver of the power of incentives (under private ownership) is the market value of alternative uses of the public infrastructure. In some cases (as in the previous example), the market value is likely to fully reward investments in quality. However, in the generality of cases, public infrastructures are not perfectly fungible for private purposes. In turn, only a fraction of investments in quality can be rewarded, which dampens incentives to invest. In some cases, no reward can be found on the private market for investments in public infrastructure quality (e.g., electricity networks). As the market value of alternative uses of the public infrastructure goes down, private ownership loses the capacity to convey incentives to invest in quality.

Third, a result similar to Proposition 2 can be obtained in any case: the incentive that is embedded in bundled contracting simply adds to the (possible) incentive that is determined by private ownership over public infrastructure.

Fourth, the contract theory literature has highlighted that the optimal design of property rights should also take into account the nature of outsourced assets and activities that, in turn, drives the interests of government and private partners in final outcomes (Besley and Ghatak 2001; Schmitz 2015).

The policy implication of these arguments is that *the distribution of rights compounds the design of monetary incentives to determine the results of alternative contractual schemes, in frameworks affected by contract incompleteness and asymmetric information.*

Extensions and Future Directions

The contract theory literature has confirmed that PPPs may deliver relevant efficiency gains whenever some form of externality exists between sequential tasks that constitute a public project cycle. Such an externality has not necessarily a technological nature, but it may also arise by financial constraints affecting private partners.

The previous arguments highlighted another crucial point, i.e., the proper distribution of risks among partners. Relying on a simple asymmetric information model, we pointed out that contracts that transfer risk to firms are useful to enforce stronger incentives but also involve additional costs for the government aiming at inducing firms to bear more risks (Martimort and Pouyet 2008; Iossa and Martimort 2015). In turn, it is crucial to assess which risks private contractors are able to handle and at which cost. Also, contractual designs should be conceived to improve appropriate risk sharing between government and firms (Engel et al. 1997).

This literature has also provided clear indications about another alleged benefit of PPPs identified by practitioners. An important result is that the *financial leverage* motive to undertake PPPs is clearly wrong (Engel et al. 2013). To put it in a very simple way, *the private financing of public infrastructures is a sort of public debt*. The reason why we observe, in the real world, a strong correlation between fiscal restraints and PPP investments is often argued to be linked to political incentives – e.g., in many countries public finance regulations may create incentives to undertake PPPs in order to bypass fiscal rules (Maskin and Tirole 2008). But such motives are not proven by compelling empirical evidence (Buso et al. 2017), and this point still needs deeper investigation.

The international experience shows that PPPs tend to work quite well in some sectors (e.g., highways, ports), while they tend to fail in others (Engel et al. 2014). On top of this, performance across countries appears to be mixed: the same kind of project may work properly in some countries (e.g., hospitals in the UK) and fail in others. From these considerations, two main questions arise. What mechanisms could explain the observed heterogeneity of PPP performance across countries and in time? Related to the previous question: how PPP performance should be measured?

Contributions to different strands of economics and management literature are trying to delve into the first issue. The institutional setting certainly plays a role to explain heterogeneity of PPP performance in time and across countries. However,

recent contributions have highlighted how, within the same institutional setting, organizational schemes based on sound business models are important keys toward PPPs' success (Villani et al. 2017). Other contributions have pointed out the role of agency problems and transaction costs within the consortium of private firms (Hoppe et al. 2013; Greco 2015). Further issues that still need improved understanding are related to renegotiations, which tend to reduce efficiency gains from PPPs (Engel et al. 2014), and are related to the lack of flexibility that, over long time spans and in particular sectors, may affect specifically PPPs (Martimort and Straub 2016).

As highlighted in the previous discussion, practitioners' debate has conveyed the idea that PPPs may be beneficial because of the market discipline they are able to introduce in public infrastructure planning. Following this argument, the mere involvement of private firms is a signal that a public infrastructure is viable from the economic and financial point of view. Clearly, this is a wrong idea: government assessment needs to precede the decision to undertake PPPs (Engel et al. 2014). However, this failed argument brings us to the very important issue of *how to measure the ex post performance of PPPs*. This issue is crucial both to assess theoretical predictions of the economics and management literature and to run policy evaluation studies. Since panel data econometrics is hardly useful in this case, because of the large heterogeneity across PPP contracts – even in the same sector, case studies or alternative econometric techniques (e.g., methods based on synthetic counterfactual) are required. This is surely an avenue of future empirical research that is worth to pursue.

Abstract

We describe the different possibilities that a protagonist has to start a process to raise rival's costs (RRC). We present the general RRC mechanism and necessary conditions to make it successful. We also expose the strengths and weaknesses of RRC theory.

Synonyms

Non-price predation

Definition

It is a strategy aiming to increase the cost of an entity's competitors in order to disadvantage and even exclude them from the market.

Raising Rivals' Costs: How It Works!

The original cases that founded the raising rivals' cost (RRC) theory relate to famous monopolization cases faced by the US Federal Trade Commission (e.g., Alcoa, Dupont de Nemours, Kellogg, and Standard Oil) where firms interfere in input or upstream markets in ways that reduce rivals' profits. In most cases, the premise of the RRC theory goes as follows: the predatory firm increases their competitors' costs by developing exclusive relationships with strategic suppliers, such as input overbuying, naked exclusion – where the supplier is committed not to sell inputs to competitors – and controlling the whole supply chain in order to prevent rivals from accessing consumption markets (Granitz and Klein 1996; Carlton and Perloff 1998; Scheffman and Higgins 2003). It is worthy to notice that the RRC strategy differs from price predation, because to be profitable, it does not require initial investments that need to be recovered (Scheffman 1992).

In order to present the RRC mechanisms and main results, let us consider the following market structure (Salop and Scheffman 1983; Church and

The authors of this essay previously investigated the strategic uses of environmental-related standards and eco-labeling schemes in order to raise rivals' costs (e.g., Grolleau et al. 2007). Hence, several parts are inspired from the mentioned previous works.

Ware 2000): a dominant firm (or group of firms), denoted D, a group of fringe rivals, denoted F, and a perfectly elastic supply for D. The marginal (and average) cost for the dominant firm c_d is lower than the marginal cost of the fringe firms, but this firm cannot produce beyond a given quantity, q_d . Moreover, assume the marginal (and average) costs for the fringe of competitive firms, denoted c_f , to be constant, but without any production constraint. The equilibrium price and quantity, respectively, denoted c_f and q^* , are presented in Fig. 1.

At equilibrium, the dominant firm is considered as inframarginal since its price is above average cost, despite a competitive market, which allows it to benefiting from inframarginal rents. Now assume that the dominant firm is able to increase the costs incurred by the fringe rivals. The equilibrium price will increase proportionally to the increase of the marginal cost of the fringe. However, the quantity produced by D will not change, while the quantity produced by F will decrease. In addition, assume that this cost is equally distributed across production units. The change in net profits of D can be written as $\Delta\pi_d^n = (\Delta c_f - \Delta c_d)q_d$. Hence, the profit of D increases if $\Delta c_f > \Delta c_d$. A sufficient condition for a profitable RRC strategy is that it increases the marginal cost of the fringe relatively more than it does for the dominant firm. Indeed, only an increase of the marginal cost of F leads to an increase of the equilibrium price. Consequently, any producer for

which an increase of the market price is beyond the increase of its average cost will benefit from a RRC strategy. Moreover, two other basic results (Scheffman 1992; Church and Ware 2000) can also be mentioned. First, an attempt to increase the dominant firm's costs does not influence the equilibrium price, although it can influence the profit of D. In other words, there is no strategic effect because the situation of F is not affected. Second, the demand has to be sufficiently inelastic in order to guarantee the profitability of the RRC strategy. Indeed, if the demand is highly elastic, the price will not increase despite a marginal cost increase of F. The fringe producers will rather exit the market.

Based on the seminal works of Director and Levi (1956), Nelson (1957), Williamson (1968), and Salop and Scheffman (1983), scholars examined the relevance of RRC strategies in various domains such as free trade agreements (Depken and Ford 1999), advertising, lobbying for product and/or environmental-related standards (Hilke and Nelson 1984; Grolleau et al. 2007), agro-food systems (Barjolle and Jeanneaux 2012), pollution regulation (Sartzetakis 1997; Lyon 2003), and stock exchange (Harris et al. 2014). In general, these studies provide, explicitly or not, evidence to the relevance of using the RRC theory in analyzing specific organizations of the considered markets. Moreover, Normann (2011) recently provided experimental evidence in favor of the

Fig. 1 Raising the costs of
a competitive fringe
(Inspired from Church and
Ware 2000, 629)

hypothesis that vertically integrated firms have an incentive to foreclose the input market to raise its downstream rivals' costs. Nevertheless, several scholars developed arguments against the RRC theory, in particular regarding its "real" potential to analyze antitrust cases (e.g., Lopatka and Godek 1992; Coate and Kleit 1994). (Given the large literature, we only provide a general overview of the arguments against the RRC theory, without purporting to be exhaustive.) For instance, the RRC theory is often analyzed through its vertical aspects and consequently its contribution to the existing competition analyses can be considered rather weak (Brennan 1986). Indeed, a RRC strategy requires that the predator is assumed to look for a monopoly on a relevant input market, which makes it a particular case of preceding competition analyses. Similarly, Church and Ware (2000) argue that some RRC cases can be also analyzed through the lenses of other theories. Moreover, the required conditions for RRC strategies are so constraining that it turns unlikely to have a significant anti-competitive effects (Coate and Kleit 1994). In addition, the costs of excluding rivals could be also higher than the derived benefits. Furthermore, Boudreaux (1990) points out the fact that the RRC theory does not take into account competitors' counter-strategies. Interestingly, while S. Salop and D. Scheffman developed the RRC theory, they admit that their works have some limits mainly encompassing the following concerns:

1. The theoretical ambiguity of the RRC effects, especially because a RRC situation does not necessarily correspond to an anti-competitive behavior
2. The lack of a framework allowing to distinguish intentional RRC strategies and other types of competition that also alter rivals' situation
3. The focus on particular market structures that may not reflect real-world settings
4. The lack of an analysis regarding the whole effects in terms of well-being (Salop and Scheffman 1987; Scheffman and Higgins 2003)

Conclusion

We presented a general description of the RRC theory. We pointed out the necessary conditions for a profitable RRC strategy and the effects of its implementation, although such effects are often ambiguous. We believe that RRC theory offers promising insights in domains that were not initially considered or extensively studied such as environmental regulation or standards. RRC strategies are sometimes difficult to detect and can be justified by other issues such as environmental conservation or public health. Interestingly, these issues can also lead to "strange" coalitions, such as the one between Baptists and bootleggers described by Yandle (1983). Hence, given the multidimensional nature of RRC, the net welfare effect can remain ambiguous and makes it difficult to craft adequate remedies. Such a result can be discouraging for antitrust authorities.

severity of punishment, the kidnapper's willingness to kill the hostage, and the value of the hostage life from the point of view of the family. Limiting the family's ability to pay reduces the frequency of the offense but opens the possibility of unintended consequences in terms of fatalities and duration of abduction.

Definition

Kidnapping in its widest sense occurs when a person carries away another person by force or fraud with the intent to exploit the abduction for a variety of purposes. Ransom kidnapping refers to a situation in which the overriding purpose for the act is a payment (usually a sum of money) for the release of the hostage and the enrichment of the perpetrators. It is a serious crime causing not only economic losses but also pain and suffering, often in the form of post-traumatic stress disorder (PTSD) and major depression (MDD), to the victims and their families. Occasionally it ends in death.

Ransom Kidnapping

Abstract

The practice of kidnapping for ransom, a predatory crime carried out mostly by criminal organizations, is a salient phenomenon in many regions of the world. It causes serious harm not only to victims and their families but also to private and social capital. As a paradigmatic rational crime involving negotiations, the incentives to commit the crime and the way it ends change with the probability and

Introduction

Kidnapping for ransom, also referred to as economic kidnapping or profit kidnapping, is a predatory crime carried out mostly by criminal organizations, rather than single offenders, usually after careful planning of the various stages of the (illegal) production process. The latter, in perfect business style, begins with a market analysis designed to identify the most profitable opportunities and to evaluate the benefits and costs of the different options in light of the strengths and weaknesses of the organization. Specialized gang members/units are required for carrying out the activity: e.g., for targeting victims (so-called spotters), holding the hostage (a tricky task often performed by someone difficult to track, like an absconder), communicating with the parties involved (media, families, police, negotiators: both formally and through the grapevine), providing food to hostages and guardians, and collecting

and cleaning the ransom (be it hard cash or any other resource with financial and/or social value). Depending on the nature of the criminal partnership and its specific market segment (see below), the production chain may include reinvestment of the proceeds in higher-value illegal markets, like the international drug industry, and/or further actions designed to secure a dominant position for the parent organization both in the underworld and the upperworld (as in the case of mafia-type or terror-affiliated groups).

Despite the relative complexity of the structures and tasks capable of sustaining a successful ransom kidnapping business, this type of crime is seldom classified as *organized crime*. The distinction between (even highly organized) ordinary illegal firms and organized crime, which may be relevant for the criminal justice system responses to the problem (see Garoupa 2007), is still controversial among both scholars and practitioners (see the digital collection by Klaus von Lampe www.organized-crime.de/organizedcrimedefinitions.htm; Varese 2010). Clearly, neither the earlier descriptive definition by Donald Cressey (1969) of organized crime as an entity “rationally designed to maximize profits by performing illegal services and providing legally forbidden products demanded by the members of the broader society” nor the insightful characterization by Thomas Schelling (1971) of organized crime as the underworld counterpart of monopoly and not just organized business mirrors the multifaceted phenomenon of ransom kidnapping across time and places. However, reversing the perspective and looking with Schelling at the factors that make an illegal activity a prime target for organized crime (basically victimized criminals should have no ready access to the law, they must find it difficult to hide from the “protector” and to carry away their business in an attempt to escape, and their earnings must be easily monitored and flow smoothly and regularly), it may be argued that an appropriative activity like ransom kidnapping does not lend itself to be monopolized. Moreover, being based on a relatively simple technology with generally modest overhead costs, the requirements for a large-scale firm are hardly met. Alternatively, adopting Williamson’s

(1985) view that organizational variety arises primarily in the service of transaction cost economizing, the activities of organized criminal firms “will be guided primarily by the relative costs of completing illegal transactions within the market versus within a downstream firm” (Dick 1995).

While the debate on the nature of organized crime (Peltzman and Fiorentini 1995) goes on, the evidence gathered so far on ransom kidnapping and organized crime worldwide shows very different patterns within and between countries. In Italy, for instance, ransom kidnapping has been a key source of liquidity, to be invested in real estate development and in the drug business, for both the ‘Ndrangheta and the Sicilian Mafia since the early 1960s. By contrast, the rural gangs of Sardinia that dominated the kidnapping business in the country for two decades (late 1950s through the 1970s) never tied to or behaved as classic organized crime. Likewise, within the top seven Mexican trafficking organizations, only the Zetas and the Beltran Leyva indulged in kidnapping (Astorga 2012); with the crackdown on drugs, however, many former criminal members of all such cartels found it profitable to switch to organized kidnapping (a similar pattern has recently emerged in Kenya and Somalia as a result of the amplified efforts to crack down on piracy). In Nigeria, where the kidnapping business emerged in the 1990s, this type of crime is associated with wealth-oriented secret societies, untouchable secret sorcery society, and “419” fraud syndicates (Ebbe 2012). Finally, as reported in Levitt and Rubio (2000), a strong causal link between kidnapping and the scope of guerrilla activities has been found in Colombia over the 1990s.

In recent years, against the backdrop of rapid globalization and increased pervasiveness of ICT (information and communications technology), kidnap and ransom has become a billion-dollar industry in which major changes have taken place. Next to classic ransom kidnapping, new categories have flourished, with peculiar traits that deserve attention for both credible research and improved enforcement.

Insider kidnapping: criminals buy inside help from employees of target companies/resorts

to access key information for the abduction to take place.

Express kidnapping: abductions have minimum duration (typically less than a day) and are calibrated in order to extract maximum cash withdrawal from ATM, for example, using the victim's payment instruments or to get a quick ransom from his/her family or company.

Tiger kidnapping: one or more individuals are abducted to coerce another person to commit a crime – which can be anything from robbery, extraction of a ransom, to murder – for the benefit of the kidnappers.

Terrorist kidnapping: motivated by financial and political reasons, it operates in politically unstable countries exploiting both domestic and international networks to carry out the abduction and to launder the ransom; it involves mainly foreign victims – often from profiled nationalities – and although the demands may start out politically motivated, they may transition to financial benefits as the negotiations progress.

Piracy for ransom: incidents take place in maritime zones in which the right of State sovereignty do not apply and comprise both physical capture of cargo from a vessel and demanding a ransom in exchange for the vessel, crew, and cargo; it represents a multi-jurisdictional challenge whose escalating figures, concerning both frequency of attacks and average ransom payments, are posing serious threats to the financial, insurance, and shipping system.

Virtual kidnapping: the supposed victim is lured or forced into a place in which it is impossible or difficult to communicate or be contacted, at the same time a family member receives calls by someone who claim to have kidnapped their loved one and demand a ransom to freed the hostage.

The global kidnapping epidemic has brought close cooperation between jurisdictions, as well as effective implementation by the largest number of countries of international standards and preventing measures against money laundering, terrorist financing, and corruption, to the forefront. In the transnational setting, however, the differing

public good aspects of defensive and proactive measures magnify the risk of collective action failures when implementing such policies, with potential oversupply of the former and undersupply of the latter (Enders and Sandler 2005).

In order to gain a deeper understanding of the kidnapping for ransom phenomenon and its control, the rest of this entry will review three related aspects: the incidence of modern-day ransom kidnapping around the world, the theoretical framework providing insights into the strategic problems faced by the kidnapper and by the hostage's family, and the lessons from applied studies of kidnapping on two selected policy issues: assets freezing and marginal deterrence.

Modern-Day Ransom Kidnapping

Whereas the practice of kidnapping is as old as recorded history and is mentioned in ancient texts from all over the world, kidnap for ransom as the crime is understood today is a relatively recent phenomenon. According to Wright (2009), it was in the late nineteenth and early twentieth centuries that legislation defining the crime and prescribing harsh punishments for the perpetrators was formally adopted for the first time in many places. In the USA, for instance, seven states passed their first anti-kidnapping laws, and 18 others stiffened penalties, in the first two decades of the twenty-first century. The Federal Kidnapping Act was passed in 1932 after the son of the America's hero Charles Lindbergh was kidnapped and killed. By that time many European countries with different legal traditions had already implemented their laws, although new provisions and amendments have continued until recently in order to catch up with the evolving nature of the crime and the surge of hostage taking by terrorists.

Despite efforts by UNODC (United Nations Office on Drugs and Crime) to collect comparative data on recorded crime in member states, the available information is still heterogeneous in many dimensions (definition of crimes, periodicity, details, and so on) and does not provide a reliable basis for cross-country analysis. Both scholars and practitioners have to rely on a mix

of sources, like extracted information from newspaper accounts, historical reconstructions, and official statistics when ransom kidnapping as a separate offense category among the index crimes is available. It is well known that since its modern-day inception, ransom kidnapping flourished in the first half of the twentieth century in the USA and in the second half in Italy. Studying the *New York Times* files on kidnapping incidents, Alix (1978) reports 1,703 cases of kidnapping occurring almost entirely in the USA between 1874 and 1974 (about 1.7 per year), including 236 classic kidnappings for ransom. The crime reached its peak in the 1930s, disappeared during the next 40 years, and reappeared dramatically in the 1970s when it became a politically motivated symbolic act of power. Yet, compared to criminal homicides (with about 7,000 cases in each of the years 1924–1974), the contribution of ransom kidnapping to total crime was modest.

By contrast, kidnapping for ransom in Italy in the period 1960–2000, with 592 cases and an average of 14.4 abductions per year, had a dramatic impact and placed the country at the top of the worldwide kidnapping hot spots throughout the 1970s and most of the 1980s (Wright 2009). Failed attempts are excluded from this count, which is based primarily on a unique archive by the former law enforcement official Luigi Casalunga (2013). Exploring the dataset, the frequency of kidnappings spiked in the late 1970s (73 incidents in a single year), continued at remarkable levels through the mid-1980s, and then slowly declined in the following decades.

In this scenario, the island of Sardinia played a special role. As documented in Marongiu and Clarke (2004), the island – despite being an organized crime-free region – had a long-standing tradition on kidnapping dating back to more than 500 years. In the time span 1960–2013, around 27% of Italy's ransom kidnappings took place in Sardinia, resulting in 162 incidents against 118 in Lombardy and 96 in Calabria: 10.6 cases per 100,000 residents, i.e., ten times the national rate. In those years, Sardinian bandits were global players and spread the crime all over Italy. They were responsible for 39 out of 40 incidents in the 1960s, 62 over 258 in the 1970s, and 39 over

249 in the 1980s. To the kidnap epidemic contributed also gangs associated with organized crime from Calabria ('Ndrangheta) and Sicily (Mafia). While the former, having found a congenial operating habitat out of the Aspromonte, ran the business until recent times, the latter withdrew pretty soon for fear of additional police controls and negative reputational effects brought about by such heinous crime.

Nowadays, in many areas of the world, kidnapping is a flourishing criminal industry, with wide direct and indirect impacts on victims and society at large. According to the Control Risks Group, an international risk consultancy, at the turn of the century economic kidnappers globally would take home well over \$500 million each year. Countries involved include Colombia, Mexico, Brazil, Philippines, and Venezuela. In Colombia, where the fraction of kidnappings of firm managers and firm owners were just under 10%, it is calculated that this type of kidnapping has a statistically significant negative relationship with corporate investment (see Pshiva and Suarez 2010). In the last decade, however, the kidnapping activity has declined both in Colombia, where the annual reported kidnapping incidents went from about 3,500 cases in the year 2000 to “only” 282 10 years later (Fink and Pingle 2014), and in the rest of Latin America. Meanwhile, kidnap numbers have soared in Nigeria, India, Lebanon, Iraq, and Afghanistan, while Mexico confirms its primacy with the highest number of kidnaps for ransom recorded worldwide (roughly 2,000 cases in 2010). According to *Alto al Secuestro*, a foundation that assists victims in Mexico, between December 2012 and February 2014, there were 4,051 kidnapping victims nationwide, of which 2,922 had been freed, while 1,129 were still being held. As the very affluent targets are adopting effective defensive measures, kidnappers are increasingly switching to middle-class workers, small business owners, students, and mid-level professionals, which now make up about 70% of the total victims.

As a matter of fact, Latin America has lost its leadership in favor of African and Asian countries, which represent the new frontier for this typology of criminal activity. In 2004 about 55%

of the world's recorded kidnaps for ransom were in Latin America, while in 2012 the region accounted for only a quarter of the incidents, and Asia and Africa made up slightly less than 75% (with about 50% for Asia excluding the former USSR and with 22% for Africa).

Deeper international economic integration, greater political instability (e.g., in the former Soviet Republics and in the Middle East area), and growing interest by international tourists for adventure holidays have created new opportunities and brought about new potential victims for profitable kidnapping. In fact, it is no coincidence that kidnappings of foreign nationals globally have increased by 275% over the 2000s (Kassim and Mohamed 2008). Furthermore, since 2005, the Horn of Africa, particularly the Gulf of Aden (Somalia) and Arabic Sea, has risen to prominence as a new hotspot for maritime piracy, particularly kidnappings for ransom.

At present, ransom kidnapping is a thriving industry in developing regions, while it has virtually disappeared in North America and Europe, which together represent only about 1–3% of global activities. This polarization can be even more extreme in light of the under-reporting and under-recording biases of the official crime data, which are presumably more serious in the former countries.

Interactions Between the Kidnapper and the Victim's Family

In 1976, scholars and practitioners from all horizons of game theory, physics, psychiatry,

and behavioral sciences and from private and public institutions gathered in Santa Margherita, Italy, for a seminar on the control and prevention of hostage taking organized by the Institute of Criminal Justice and Criminology of the University of Montreal in cooperation with the International Centre for Comparative Criminology of the University of Maryland (Crelisten and Laberge-Altmejd 1976). On that occasion, Reinhard Selten (1976) presented a two-person game model to gain insight into the strategic problem faced by the kidnapper (K) and the hostage's family (F). Nowadays, versions of the model feature in microeconomics textbooks to illustrate the structure of dynamic games and the notion of subgame perfection (Harrington 2014). Yet, it still represents the basic theoretical reference for the analysis of hostage-taking events. The extensive form of this game is represented in Fig. 1.

At the top of the decision tree, agent *K* makes the first move deciding whether to kidnap the victim or not. If he chooses the latter, the game ends with zero payoffs. If, instead, he chooses to kidnap the target, he announces a ransom *D*. Then, the victim's family *F* either accepts the demand from *K* or makes an alternative offer *C*. In both cases, in turn, the kidnapper will decide to release or kill the hostage.

If the family accepts the ransom requested ($C = D$), the criminal will rationally decide to release or kill the victim according to the expected payoffs V_R and V_K . If the family offers an unsatisfactory amount ($C < D$), then the kidnapper could feel offended and frustrated at the low offer and might react killing the hostage.

Ransom Kidnapping,
Fig. 1 The extensive form
of the game

It is assumed that the probability associated to this extreme reaction is equal to α , which is a function of the distance between the amount offered (C) and the amount requested (D):

$$\alpha = a(1 - C/D) \quad (1)$$

where a is a parameter ranging between 0 and 1, which measures the kidnapper's propensity to sanction noncompliant offers. As one can see, the higher the $C - D$ gap, the higher the value of α ; when $C = D$, the likelihood of this sanction equals zero.

The subgame-perfect equilibria of the game shown in Fig. 1 can be investigated by backward induction. Starting at the game's final decision nodes and analyzing player K 's choice, we see that he prefers to release the hostage if (and only if) the following relation holds:

$$V_R > V_K \quad (2)$$

where

$$V_R = (1 - q)C - qx \text{ and } V_K = -y - qz. \quad (3)$$

Briefly, V_R and V_K represent the kidnapper's expected gain in the two regimes (release or kill), where (q) is the probability of being arrested

by the police, (C) is the ransom paid, ($-x$) the disutility of being caught, ($-y$) the disutility associated with the killing of the hostage, and ($-z$) the disutility of being caught in case the victim is executed.

Since $C > 0$, $y > 0$, and $x \leq z$, the relation Eq. 2 always holds true, the kidnapper will never rationally decide to execute his threat. Moving to the upper node of the decision tree, player F has to choose the optimal offer C that maximizes his utility U taking into account the likelihood of a violent reaction by K :

$$U = (1 - \alpha)W_R + \alpha W_K \quad (4)$$

where

$$W_R = -(1 - q)C \text{ and } W_K = -w. \quad (5)$$

The parameter w captures the value of the hostage's life from the point of view of the family. Equation 4 shows that, on the one hand, the family F benefits from an offer reduction, but on the other hand, this strategy increases the probability of a sanction threat from K . So, the hostage's family will propose an offer C^* that maximizes its utility function. Equation 4 attains its maximum at C^* which can be interpreted as the best response given a , q , w , and D . Therefore, the optimal offer C^* is given by Eq. 6:

$$C^* = \begin{cases} D & \text{for } 0 < D \leq \frac{aw}{(1+a)(1-q)} \\ \frac{w}{2(1-q)} - \frac{(1-a)D}{2a} & \text{for } \frac{aw}{(1+a)(1-q)} \leq D \leq \frac{aw}{(1-a)(1-q)} \\ 0 & \text{for } D \geq \frac{aw}{(1-a)(1-q)} \end{cases} \quad (6)$$

Notably, C^* is increasing in D in the interval $0 < D \leq \frac{aw}{(1+a)(1-q)}$ and then decreasing up to

$$\frac{aw}{(1-a)(1-q)}.$$

As a matter of fact, in the upper subgame agent K sets D in order to extract the largest offer from

player F . It follows that the optimal value D^* is the following:

$$D^* = C^* = \frac{aw}{(1+a)(1-q)} \quad (7)$$

When Eq. 7 holds true, player F will accept the kidnapper's offer, D^* , and the latter will release the hostage.

Finally, looking at the first node, the kidnapper has an incentive to engage in the act of kidnapping when $V_R > 0$, which means

$$\frac{aw}{(1+a)} > qx \quad (8)$$

According to Eq. 8, kidnappings can be discouraged by increasing x or q and by decreasing a or w . Both x and q can be influenced by public policies, for instance, hardening punishment and spending more resources in detecting criminals. However, the effect of severity on x can be very tenuous in practice (Paternoster 2010), whereas the effect of increasing q can be less effective than expected due to its impact on the optimal offer from the family (which in case of capture recovers any ransom paid). This latter possibility can be mitigated by restricting the family's ability to pay. As for w , which cannot be influenced directly by public measures, it may be noted that it may affect the choice of kidnappers as to which member of the family to kidnap. The individual parameter a , instead, can partially be influenced by recommendations from the police and/or the insurance company on the way to handle the negotiations with the kidnappers.

By contemplating the possibility of an extreme reaction by the kidnapper, Selten's model bypasses situations in which one or both agents have a dominant strategy and succeeds in providing a compelling negotiation framework.

Going back to Fig. 1, if one removes the possibility of such reaction, $V_R > V_K$ and the kidnapper will always release the hostage. Hence, the optimal strategy for player F , given the dominant strategy of K , is not to pay the ransom D . The unique equilibrium is represented by the zero-payoff outcome. The choice of rational kidnappers, with no reputation to defend, does not depend on the payment but rather on the balance between the increased penalty in case of murder of the victim and the increased probability of being caught if the victim is left alive. Why then are people often willing to pay ransom?

To make sense of this puzzling result, referred to as "the mystery of kidnapping" (e.g., Gintis 2009), a modified model is required. For instance,

with Harsanyi (1967), one can hypothesize the existence of two types of kidnappers: vindictive and self-regarding. So, for some values of p_v , the share of vindictive individuals among all kidnappers, the best strategy of the family is to pay the ransom. Alternatively, the family could incur additional psychic costs if a ransom is not paid (Gintis 2009). Then, a ransom would materialize as long as such additional costs exceed the kidnappers' request (but again the victim will be released only if the cost of freeing is less than the cost of killing the victim).

Hindering Ransom Payments

In order to fight ransom kidnapping by reducing its anticipated net benefits, both defensive and proactive measures can be adopted. Relative to the second type of measures, countries like Venezuela, Colombia, and Italy have banned both ransom payments and kidnap insurance, and the freeze of assets of the victim's family is often automatic. Despite the growing international consensus on similar measures in the case of terrorist-related kidnapping, these policies are highly controversial. As noted by Block and Tinsley (2008), "one may as well enact legislation forbidding a mugger's victim from responding "life" to the threat of "your money or your life." To some extent such measures end up punishing the victim rather than the criminal, and, in any event, most people would see it as an unacceptable restriction of personal liberty. The standard justification is that ransom payment and insurance impart a negative externality on future victims, and by eliminating them the incentive to perpetrate kidnapping would disappear. Recent contributions uncover more subtle issues.

Fink and Pingle (2014), investigating within Selten's framework the impact of kidnap insurance, find that – under the assumption that kidnappers have a positive net willingness to kill – a market for kidnap insurance can benefit risk-averse agents, as long as it does not increase the risk of kidnapping too much. Individuals should fully insure in the latter case and partially insure otherwise. Since an insurance market enables the

families to rescue their loved ones from kidnap-
pers more prone to murder but it may also increase
the likelihood of kidnapping, the total effect on
the number of kidnapping deaths is indeterminate.
However, if the likelihood of kidnapping is only
marginally affected, then a law banning kidnap
insurance implies more fatalities.

Preventing ransom payments may have an
impact not only on the risk and fatalities of kid-
napping but also on the duration of the kidnapping
experience. An extended duration escalates the
harm of the crime. Detotto et al. (2014) study
this problem in a simple setup in which as time
passes the family becomes more willing to pay the
ransom and the kidnapper balances the benefits
and costs to extending the duration. The optimal
stopping period, where K is no longer willing to
take the chance of being caught to increase the
amount collected in ransom, implies that duration
grows inversely with the initial ransom offer, the
probability of apprehension during the kidnap-
ping, the probability the hostage dies or flees, the
maintenance costs, and directly with the incre-
mental increase in the ransom. Exploiting a
micro-dataset on kidnapping incidents in Sardinia
between 1960 and 2010 to estimate a semi-
parametric survival function, the authors find
that the anticipated apprehension probability
does not have a significant effect on duration,
whereas the asset-seizure policy has mixed

effects: it leads to significantly shorter abductions
(i.e., an express kidnapping), but if a kidnapping
is not express some evidence is found that, in fact,
duration might expand as the policy creates fric-
tions in the collection of the ransom for the family
(see Fig. 2, in which the vertical line corresponds
to the year of implementation of the asset-seizure
policy). The polarization is dramatic: to the right
of the red line, kidnappings are either very short
(less than a day on average) or very long (about
200 days on average).

Taken together with the observation that the
frequency of kidnappings dropped significantly
after the adoption of the asset-seizure policy,
these results support interventions directed to
reduce the anticipated benefit to kidnapping rather
than focus on the costs.

Increasing Penalties for Kidnappers

Deterrence is a central concept in the economic
model of crime (Becker 1968) because potential
offenders rationally (though not necessarily con-
sciously) consider and balance the costs and ben-
efits of committing a crime. In this framework,
criminals opt between legal and illegal activities
according to their utility and budget constraint. In
the real world, however, criminals not only must
choose the optimal allocation of effort between

Ransom Kidnapping,
Fig. 2 Kidnapping
duration over time

legal or illegal activities, but they may allocate their effort between several crime offenses. The idea of marginal deterrence recognizes that the setting of sanctions for one particular offense not only affects deterrence of that crime but also affects the incentives to engage in other activities. In his pioneering analysis of the subject, Shavell (1992) explicitly refers to the classic example of kidnapping/murder as an application of marginal deterrence.

Recently, Detotto et al. (2015) propose a reasonable application of the theory of marginal deterrence related to kidnapping and its complement, murder. While the death exposes the criminals to punishments, if the sanction for kidnapping is great, then the marginal sanction for homicide is reduced.

They use a unique data set of kidnappings in Italy between 1960 and 2013 to test the theory of marginal deterrence. Kidnapping was a major concern for Italy in the 1960s, and, as a consequence, in 1974 a new set of sentencing policies were set with greatly enhanced punishments for the crime. Precisely, the range penalty passed from imprisonment for 8–15 years to 10–20 years, if the ransom was not paid, and from 12–18 years to 12–25 years, if the ransom was actually paid. Such reforms, though, did not change the sanction for murder which was punishable with 21 years to life

sentences. Thus, marginal deterrence of death reduced. Later, in 1978 in response to increased homicides, the Italian government escalated sanctions for deaths resulting from kidnappings, addressing the marginal deterrence problem. The new change law enacted in May 1978 specifically increased the sanction for deaths associated with kidnapping.

Figure 3 provides illustration of kidnapping-related deaths over time. The vertical dashed lines denote the policy changes. As the theory of marginal deterrence predicts, the adoption of the enhanced sanctions for kidnapping in 1974 resulted in an increase in the prevalence of death, while the latter became minimal after the 1978 policy.

To test the hypothesis that the changes in the sanctions affected the incentive to murder the victim, a binary probit model is estimated with the dummy variable death as the dependent variable and the characteristics of the victim, time of year, and location as the controls. The results in Table 1 provide confirmation of the theory. The adoption of the enhanced sanctions for kidnapping in 1974 resulted in an increase in the prevalence of death. Precisely, the marginal effect is estimated to increase the likelihood of death occurrence by 4%. Then, according to the predictions of the theory, the escalation of sanctions

Controls: victim occupation, season, and region of capture (I): 1974 and 1978 are lagged 3 months, (II): 1974 and 1978 are leaded 3 months, (III): dropped all obs. in the range [−3, +3] months of both 14 October 1974 and 18 May 1978

for kidnap-murders of 1978 reduced the prevalence of death, which, in numbers, is estimated to have declined by 5%.

Conclusion

While the categorization of kidnapping for ransom as organized crime is uncertain, in many regions of the world modern-day hostage taking for ransom is carried out mostly by highly organized criminal firms on a historically unprecedented scale. Recent trends show a blurring of the boundaries between ransom kidnapping, piracy, and terrorism together with an increasing international dimension that parallels contemporary legal globalization. The contributions reviewed in this entry stress the importance of both classical instruments and more controversial measures, like banning ransom insurance and/or ransom payments, to counteract the crime. However, given the likelihood of unintended negative effects (on fatalities, duration of the kidnapping

experience, and burden falling on enterprises) in some environments, policies aimed at reducing kidnapper’s anticipated benefits through these channels must carefully balance the benefits for society at large against the higher costs imposed on specific groups.

Definition

Rationality involves the evaluation of choices to achieve a goal or to find the optimal solution to a

problem. Simon (1972, p. 161) defined rationality as “a style of behavior that is appropriate to the achievement of given goals, within the limits imposed by given conditions and constraints.”

Introduction

The notion of rationality has become a central idea in the various disciplines within the social sciences. This entry discusses the concept of rationality, which has been a core concept in the explanation of human behavior in economics and the other social sciences. In the field of economics, it is expected that individuals behave rationally and that organizations should make rational decisions. A substantial number of economic theories are established under the assumption that when individuals act they do so in a rational manner. Simon (1957) revises this assumption by proposing the idea of bounded rationality. The concept of bounded rationality accounts for the fact that a perfectly rational decision cannot be made because of shortcomings that individuals face with regard to the inadequacy of information, the time constraints, and the limitations to their cognitive processes. This entry gives particular emphasis to subject areas within economics where rationality plays an important part in the formulation of theories and in explaining behavior, particularly the economics of crime.

The structure of the entry is as follows. We start the entry by examining the concept of rationality in economics. The entry proceeds by analyzing the influence of economic rational choice theory on the development of an economic theory of crime and its impact on crime and in the crafting of policy. The last section concludes the entry by offering some key observations and directions for future research.

Rationality and Economics

Karl Popper’s 1967 essay, “The Rationality Principle”, was one of the first studies that linked the concept of rationality to social sciences (Karl Popper 1967 essay in Miller 1985.) According to

Popper’s principle, one should analyze social processes by assuming that “agents always act in a manner appropriate to the situation in which they find themselves” (p. 361). Popper’s view of rationality embraced a notion of situational analysis, and he went on to note that it is able to explain, “. . .the unintended social repercussions of intentional human actions” (Popper 1945/1966, p. 95). This concept by Popper was strongly criticized by many as it did not seem consistent with his principle of falsification. Others, such as considered the rationality principle to be consistent when taken with the view that it is “approximately false” and can be falsified in very rare cases.

Popper went on to contend that situational analysis is an approach employed by economics; this according to other researchers can be classified as neoclassical rationality. Langlois (1997) in his paper noted that the assumptions of the basic neoclassical model can be divided into four categories:

1. *Self-interest*: According to Langlois (1997), self-interested behavior can actually be categorized as purposeful behavior, and this purposefulness as pointed out by Vanberg (1993) is one of the more appealing elements of the neoclassical model. This assumption has been heavily criticized by researchers both in and outside the field of economics. This according to Langlois (1997) is because of a tendency to misidentify self-interest with selfishness.
2. *Omniscience*: This second assumption is another way of saying “perfect competition,” which in neoclassical theory means that agents have perfect information with respect to a particular structure set out for them by the analyst. An example of this is the general equilibrium theory developed by Arrow-Debreu where economic agents are required to know all the utilities and production possibilities of all other agents. Langlois (1997) criticized this assumption based on the type of knowledge that economic agents are expected to have. He noted that the neoclassical model expects agents to have “structural knowledge” (full knowledge of the structure of the economic problem that they face) but not “parametric knowledge”

(full knowledge of all the parameters). He went on to state that in neoclassical theory it is generally the case to relax the assumption of “perfect knowledge” but this falls more often on the side of “parametric knowledge.” This is problematic because more often than not people are ignorant of the very nature of the problem situation they face.

3. *Conscious deliberation*: The third assumption of the basic neoclassical model is that agents are consciously considering their options and then choosing among them. Langlois (1997) noted that as the field of economics has become more mathematical, economic agents are now solving more complicated problems through deliberation. Friedman (1953) presented the only alternative to this assumption noting that economic agents do not actually deliberate but rather behaved “as if” they had. This alternative view has not been readily accepted by most students of economic methodology.
4. *Representative agent*: Alfred Marshall (1961) established the assumption of the “representative agent.” Marshall (1961) defined the representative firm as one that represents the typical properties of the population of firms as a whole and not just the properties of any particular firm. According to Langlois (1997) this definition was used so that some measure of “population” thinking can be accommodated in the theory of comparative statistics.

Rationality, in particular, is applied to the concept of game theory which is an essential aspect of microeconomics. Rationality is a central assumption of game theory irrespective of the different variations of the game that exist. In the context of game theory, a rational player is one who always chooses his/her most preferred outcome given the expectations of his/her opponent. Game theory according to Turocy and Stengel (2001) is defined as “the formal study of conflict and interest”. Antoine Cournot (1838) was the first to discuss this in his study of duopolies. By the 1950s and the 1960s, the analysis was broadened to deal with problems like war and politics, as well as sociology and psychology. Turocy and Stengel (2001) noted that the strength in game theory is that it

provides a structure for analyzing problems of strategic choices. Turocy and Stengel (2001, p. 5) in describing how game theory works noted that “The process of formally modelling a situation as a game requires the decision-maker to enumerate explicitly the players and their strategic options, and to consider their preferences and reactions.”

The “game” in game theory involves modeling a situation that involves several players. Games can be categorized depending on the level of details involved in the process. For instance, there is coalition/cooperative game theory and then there is noncooperative game theory. The cooperative game theory requires a high level of description, and it investigates the power among different coalitions or as Turocy and Stengel (2001, p. 6) state it, “how a successful coalition should divide its proceeds.” This type of game theory is most suited to situations in political sciences and international relations where “power” plays an important role. Noncooperative game theory is more concerned with how strategic choices are analyzed. It requires less details as it focuses more on the ordering and timing of players’ choices as this is considered to be vital in determining the outcome of the game. This game is distinguished from cooperation because the modeling is done around the fact that players are making choices in their own interest, and while some cooperation might take place, it is only when players find it in their best interest. The ultimate goal of game theory, regardless of what type of game is being played, is to predict how the game will be played by rational players or at least how best to play rational opponents.

Prisoner’s dilemma is one of the most popular examples of game theory in social sciences. The game occurs between two players where each player has two strategies, cooperate or defect. The term was coined by Albert W. Tucker in 1950 to describe a situation where two prisoners are taken into custody but the police officers only has evidence to arrest one of them (Holt and Roth 2004). The details of the game are that both criminals are questioned separately at the same time and thus they do not know what the other says – this is a simultaneous game. The prisoners

are then presented with different outcomes in an attempt to persuade them to confess to the crime. At this point both prisoners are aware of the same deal and know the consequences of their decision, which brings in the assumption of complete information and complete knowledge.

In Prisoners' dilemma the defect strategy dominates the cooperate strategy. It is assumed that a rational player will never choose to play a dominated strategy since the player will always be better off by switching to the other strategy. Thus within this game players will always choose to defect and some view this as an inefficiency of the model. One way that this can be overcome, as pointed out by Turocy and Stengel, is by playing the game repeatedly so that the cooperation strategy can be viewed as rational behavior to the players. In other words the fear of punishment in the future outweighs the benefits of defecting in the present.

Rationality, Deterrence, and Crime

Within the rational choice model used by economists, a new theory of criminal behavior was shaped to form what is known in the economics of crime literature as deterrence theory. Akers (1990) highlighted the link that binds deterrence theory to rational choice theory. He noted that both theories were based on the foundation of the utilitarian view of rational human behavior. Specifically Akers (1990, p. 654) noted that "Both theories assume that human actions are based on 'rational' decisions, that is, they are informed by the probable consequences of that action." He noted that for rational choice theory, an individual takes all his/her actions, whether lawful or criminal, into account when trying to maximize his/her payoff and minimize his/her cost. Similarly, for deterrence theory an individual considers the legal punishment of a crime against the motivation before engaging in the criminal behavior.

Becker (1968) was the first researcher to apply economic models of rational decision-making to crimes, and according to his work, "The economic analysis of crime starts with one simple assumption: Criminals are rational. A mugger is a mugger

for the same reason I am a professor-because that profession makes him/her better off, by his/her own standards, than any other alternative available to him/her. Here, as elsewhere in economics, the assumption of rationality does not imply that muggers (or economics professors) calculate the costs and benefits of available alternatives to seventeen decimal places-merely that they tend to choose the one that best achieves their objectives" (p. 43). In this seminal work, a supply offense function was derived which he defined as "relating the number of offences by any person to his/her probability of conviction, to his/her punishment if convicted, and to other variables, such as the income available to him/her in legal and other illegal activities, the frequency of nuisance arrests, and his willingness to commit an illegal act" (Becker 1968, p. 177).

Becker's model was then extended by Ehrlich (1973), who considered a time allocation model. Thus, in the basic economic crime model, individuals choose between allocating their time either to legitimate activities or illegitimate activities. Thus, crime and legal employment are viewed as substitute activities (i.e., if one chooses a legal activity, he/she will have less time for criminal activities), and the difference between legal and illegal opportunities is considered into the model (see Entorf and Spengler 2002). Researchers (see Entorf and Spengler 2002) have raised concerns, however, as to whether this assumption is helpful in explaining crimes by certain groups (e.g., juveniles, low-paid individuals), and made a number of important theoretical and empirical contributions to the economics of crime model since then (for a discussion see Witte and Witt 2002). The Becker-Ehrlich model, however, has formed the foundation for the literature on the economics of crime in which individuals are considered to be rational utility maximizers who take into account the cost and benefit of a crime before engaging in criminal activities, and thus, attitudes toward risk are essential to the model.

A Simple Deterrence Model

In the economic model of crime, criminals are assumed to be utility maximizers who seek to optimize their benefits under restrictions and risk

(Becker 1968). In the case of theft, burglaries, or property crime, the benefits are comprised of the material gains. In the case of violent crime, the payoffs are the transgressor utility derived from the infliction of an assault. Punishment is the major restrictor of crime since punishment is a cost imposed on the transgressor. The risk facing the transgressor is the probability of being caught. Mathematically this may be simply expressed as

$$\pi_i(s_i) = s_i(g - cp) \quad (1)$$

where i is the criminal individual, π_i is the profit from the criminal activity, s_i is the tendency for the criminal to commit a crime, g is the combined monetary and psychic payoff for a certain criminal action, c is the probability of getting caught, and p is the punishment when caught. As seen from Eq. 1, higher punishment reduces criminal activities.

A major limitation of Becker's analysis is, however, the need for strategic interaction. The detection of crime is not an exogenous variable. The detection rate of criminal activity is a function of the actions of police officers, public prosecutors, and lawyers (Tsebelis 1989; Rauhut and Junker 2009). Additionally, criminals and law inspectors are engaged in a "discoordination game." Criminals tend to be more inclined toward committing a crime when they believe that they will not be caught or punished. In contrast, law inspectors are more inclined toward the investigation and inspection of criminals if it is believed that they will detect the crimes of the criminals (Rauhut and Junker 2009).

When game theory is applied to crime, criminals and law inspectors are assumed to be in a similar state of discoordination. In this game, if the law inspector detects a criminal committing a crime, they receive a reward r . The cost of the inspection for the law inspector is also given by k , thus the game may be represented by Table 1.

Rationality, Table 1 The inspection game

		Law inspector	
		Inspection	No inspection
Criminal	Crime	$g-p, r-k$	$g, 0$
	No crime	$0, -k$	$0, 0$

The information in this table shows that if the criminal commits a crime and there is inspection, his/her payout will be $g-p$. Since it is assumed that the criminal is caught in this scenario, the reward for the law inspector will be $r-k$. This is the material gain from the inspection less the cost of inspection. If the criminal committed no crime, but the inspector did an inspection, then the reward for the criminal will be 0; however, the inspector will bear the cost $-k$. If no inspection was done, and no crime was committed, then the payoff is 0 for both parties. In the scenario where no inspection was done, but the criminal committed a crime, the criminal will receive his/her payout of g .

Mathematically the payout functions for the criminal against the inspector and the inspector against the criminal are, respectively,

$$\pi_i(s_i, c_j) = s_i(g - c_j p) \quad (2)$$

$$\emptyset_j(s_i, c_j) = c_j(s_i, r - k) \quad (3)$$

where $\emptyset_j$ is the payoff function for the inspector, j who plays against the criminal, r is the reward for the law inspector for detecting a crime, k is the cost of the inspection for the law inspector, s_i is the tendency of the criminal to commit a crime, and c_j is the probability of getting caught. The Nash equilibrium of the joint strategies may be derived by finding the partial derivative of the payout functions (Rauhut and Junker 2009). The criminal finds the partial derivative of the law inspectors' payoff function $\partial \emptyset_j / \partial c_j$ and sets it to 0. The criminal then expresses his/her probability of committing a crime as:

$$s_i^* = k / r \quad (4)$$

The law inspector finds the partial derivative of the criminal's payoff function $\partial \pi_i / \partial s_i$ [i.e., the partial derivative of the profit for the criminal activity ($\partial \pi_i$) divided by the partial derivative of the tendency for the criminal to commit a crime (∂s_i)] and set it to 0. The law inspector expresses his/her probability of successful inspection as:

$$c_j^* = g/p \quad (5)$$

The results of such game theory are counterintuitive. It suggests that higher punishment does not reduce crime; instead it reduces inspection behavior. Empirical evidence has been mixed on the relationship between crime and punishment. Gibbs (1968) found a negative association between the homicide rate and the severity of criminal punishment. Tittle (1969) found a weak-to-moderate negative association between the severity of criminal punishment and the homicide rate. Saridakis (2011), for example, found that costly deterrence-based policies adopted by governments may have a weak impact in deterring criminals from serious violent crime in the long run. In the following section, we discuss some of the findings documented in the literature and highlighted differences that have been observed between property crime and violent crime.

Empirical Evidence Based on Deterrence Model

According to the Federal Bureau of Investigation (FBI), four offenses – murder and nonnegligent manslaughter, forcible rape, robbery, and aggravated assault – are defined as violent crimes. They went on to note that any crime that involves the force of threat of violence is deemed to be a violent crime. On the other hand, property crime is defined as theft-type offenses which involve the taking of property or money. Thus offenses such as burglary, larceny-theft, motor vehicle theft, and arson are considered to be property crimes. A wide range of research has been done on deterrence theory, which assesses the impact that deterrence measures, such as the probability of being caught and punished, has both on property and violent crime levels.

Specifically, Pauwels et al. (2011) noted that there are two categories upon which research in deterrence is categorized, and these are macro-level research and individual-level research. At the macro level researchers use official crime statistics to determine the relationship between objective punishment levels and crime, while on the individual basis, they use survey methods to assess the relationship between sanctions and self-

reported crime. The Bayesian updating method is employed at the individual level and was developed by Edwards et al. (1963) and, according to Saridakis and Sookram (2014, p. 25), "... is based on a subjective belief that individuals begin with prior information, and as individual acquires more information through actions about offending and its outcomes, a rational individual would tend to rely more on this new information and less on his or her own beliefs. ..."

Using cross-sectional data from US states during the 1940s to the 1960s, Ehrlich (1996) was the first to empirically test the crime deterrence model. The results of his model showed a strong negative correlation between crime and criminal justice variables in the 10 out of 14 crime categories that he had included in the model. A major finding of the model was that law enforcement activities were not less effective in combating violent crime relative to property crime. This meant that a deterrence force acting on an individual in his/her decision to engage in crime was not stronger on violent criminal activities as opposed to property crimes. However this result was one of the few to show no distinction in the deterrence impact on property crimes over violent crimes. Woplin (1978), who used a model covering a longer time period, from 1894 to 1967, derived different results. He found that deterrence variables had a stronger impact on property crime as opposed to violent crime. Ehrlich (1996) and Woplin (1978) were not the only ones trying to ascertain the relationship and impact of deterrence variables on crime. A few examples of similar studies are from Entorf and Spengler (2000), Cherry and List (2002), Saridakis (2004), Buonanno and Montolio (2008), Saridakis and Spengler (2012), and Han et al. (2010).

Entorf and Spengler (2000) based their model on the traditional Becker-Ehrlich model but modernized it to include demographic changes, youth unemployment, and income inequality in the urban areas in Germany. In their study they were able to separate property crimes from violent crimes and they discovered that the clear-up rates for property crime were much higher than that for violent crimes. They went on to conclude that the deterrence hypothesis appeared to be

more applicable to property crime, and as such this type of crime was more directly related to a rational offender as opposed to violent crime offenders. Specifically Entorf and Spengler (2000, p. 23) noted in their paper that “For the rational offender, low legal income opportunities increase the probability of committing a crime.”

Other researchers have carried out a number of studies that analyze the deterrence hypothesis and how it relates to both property and violent crimes. In their 2012 study, Saridakis and Spengler, for example, examined the relationship between crime, deterrence, and unemployment in Greece over the period 1991 to 1998 and received similar results to Entorf and Spengler (2000). Using a generalized method of moments (GMM) model, they found that property crimes were significantly deterred by higher clear-up rates and there was a positive relationship between property crime and unemployment. Violent crime on the other hand was not significantly impacted by unemployment and clear-up rates. In explaining this result, they noted that for violent crimes, the lack of impact of clear-up rates and unemployment may be due to the fact that these crimes are driven mostly by impulsive actions, while on the other hand property crimes are generally driven more by economic incentive and rational thinking.

In assessing the relationship between unemployment and violent crimes, Saridakis and Spengler (2012) specifically found that male unemployment had a positive and significant impact on rape levels but this relationship became insignificant when other factors were considered. In terms of female unemployment, the relationship with rape was also significant but strongly negative, and Saridakis and Spengler (2012) noted that this could be explained by the routine activity theory. (Routine activity theory states that crime occurs when three elements come together which are an accessible target, the absence of an adult guardian, and the presence of a motivational offender.)

As noted earlier, one of the reasons that deterrence policy seems to work more effectively on property crimes as opposed to violent crimes is the assumption that human beings are rational. Most of the research done in this area indicates that

perpetrators of property crime tend to be more rational when deciding on whether or not to engage in this crime. This means that these perpetrators consider the consequences of their behavior before engaging in their crimes and as such they will consider any deterrence policies before engaging in the crime. Therefore, based on the assumptions of deterrence theory and on the econometric results by various authors, it can be stated that rationality is more aligned to property crimes while violent crimes are more driven by emotionality and impulsive actions rather than economic incentives.

Given that many researchers have determined that perpetrators of property crime are more rational than violent crime perpetrators, Saridakis in his 2004 paper attempted to determine the factors that influence violent crimes. In his study he examined violent crime in the United States during the 1960–2000 period and found no long-run relationships but significant short-run relationships. Specifically, Saridakis’ (2004) results indicated that because violent crimes could be motivated by a variety of reasons, it was difficult to determine direct influencing factors for violent crimes as compared to economic factors that influence property crimes. With regard to the short run, his results showed that an increase in incarceration rates led to a reduction in the violent crime rates and as such could be viewed as a possible solution for dealing with violent crime. In terms of other factors, Saridakis (2004) found that income inequality had a positive impact only on murder. For the variable alcohol consumption, the study found a positive relationship with overall violent crime, and this results fall in line with other researchers such as Raphael and Winter-Ebmer (2001), Ensor and Godfrey (1993) and Field (1990). Generally this literature provides three reasons for the positive relationship between alcohol consumption and violent crimes:

1. Alcohol tends to influence a person’s rationality when assessing the cost-benefit analysis of engaging in criminal behavior.
2. Offenders tend to consume alcohol after they have committed a crime in an attempt to excuse their behavior.

3. Users of alcohol tend to engage in more risky behavior as well as disregard their assessment of potential dangers and as such increase their chances of victimization.

In concluding his paper Saridakis (2004) noted that generally the effects of prison population on violent crimes are much smaller than that found by earlier researchers, such as Devine et al. (1988) and Marvell and Moody (1997). Saridakis further noted that, with the exception of income inequality and its positive relationship with murder, overall, economic factors tend to have an insignificant impact on violent crimes. Alcohol consumption was found to be one of the most impactful factors and thus he noted that it should be included in any study assessing violent crimes. His main conclusion was that investigating violent crimes is much more complicated than property crimes due to the fact that its perpetrators are less rational and thus there are many more motivating factors for engaging in crime and, along with other researchers such as Hartung and Pessoa (2004), concluded that the Becker-Ehrlich theory of deterrence is better suited to dealing with property crime as the many examples above show that these policies tend to have significant impacts in reducing the incidence of property crime.

Conclusion

Rationality and the theory of rational behavior have made important conceptual advances in explaining choices and decision-making and have been widely used by economists and other social scientists in various areas of research to provide solutions to different types of problems. This entry explores the concept of rationality and its role in formulating and shaping theories and in particular the association between the rationality principle and its impact on neoclassical economics. As shown rationality is a key component of the game theory aspect of microeconomics, and an analysis of the game theory example of the prisoner's dilemma is undertaken along with how rational behavior influences choices. The entry then focuses on the economics of crime

theory, in which criminals are assumed to behave as rational utility maximizers. The entry provides a detailed evaluation of rationality and the two major categories of crime – violent and property. It was pointed out, however, that the concept of rationality is better suited to formulating policy targeted to property crime rather than violent crime.

Abstract

Since 13 December 2006, the European Union is in a phase of implementation of a new harmonized legislative framework in the field of chemical industry: the REACH regulation (an acronym for Registration, Evaluation, Authorization, and Restriction of Chemicals). From a law and economics perspective, a large set of questions emerge with this regulation. In our entry, we will only shed some light on those which have already been analyzed, such as competition, data sharing, innovation, and socioeconomic analysis.

Introduction

The European REACH legislation is crucial for at least two reasons: it concerns the European chemical industry, and it is one of the most complex legislations that the European Union has ever decided to adopt and implement.

Chemical products are both found in nature and man-made. In our daily lives (food, paint, glue, ink, medication, cosmetics, etc.), they take the forms of *substances*, i.e., chemical elements and their compounds; of *preparations*, i.e., mixtures or solutions composed of at least two substances; and of *articles*, i.e., objects for which the shape, surface, or pattern are more important than their chemical components. The European Commission estimates that close to 100,000 different substances are used on the European territory. The chemical industry in the European Union is responsible for approximately 21% of world sales, is the world leader of exports, has several influential multinational corporations, and directly employs 1.2 million people.

Apart from its sectorial importance, the REACH regulation is also exceptional from the legal and institutional point of view (see Bergkamp 2013). It took almost 9 years of discussions and confrontations (1998–2006), including a White Paper (COM 2001, 88 final) and an internet consultation in May 2003 which received more than 6000 contributions, to publish this legislation in the Official Journal of the European Union on 30 December 2006, coming into force on 1 June 2007.

This legislation is originally constituted by Regulation No 1907/2006, consisting of 850 pages and 141 articles, as well as by Directive 2006/121/EC. It also creates a new European body, the European Chemicals Agency (ECHA), whose purpose is to ensure its proper application. This entry provides a presentation of the REACH regulation, which applies to all members of the EEA, in four sections: the genesis and objectives of REACH (1), the structuring principles of REACH (2), ECHA (3), and the role of socioeconomic analysis in REACH (4).

Origins and Goals of REACH

At an informal meeting in Chester on 26 April 1998, the European environment ministers engaged in a debate on community policy on chemicals. They came to the conclusion that a revision of the latter was necessary. The European Commission then assessed the four main legal instruments governing chemical substances (Regulation No 793/93 and Directives

67/548/EEC, 88/379/EEC, 76/769/EEC) and diagnosed at least three very serious problems.

First, the system made a distinction between substances marketed before September 1981 and those marketed afterward, requiring only the latter to undergo testing and assessment of risks to health and the environment. This led, as explicitly stated in the White Paper EU Commission (2001, p. 6), to “a general lack of knowledge about the properties and uses of existing substances,” since the substance of the previously existing substances represented more than 99% of the total volume of substances on the European market. In addition, it was pointed out that it seemed inadequate, inefficient, and costly to entrust the assessment of dangerousness to the authorities and not to the firms. Finally, the report stressed that current legislation only required manufacturers and importers to provide information on their products, thus neglecting all data on downstream uses (industrial users and formulators).

With this in mind, the European Commission set out in the White Paper of 27 February 2001 a number of proposals for action and the draft of a concerted European policy to solve these problems, thus initiating the steps that would lead to the adoption of REACH. It should be noted that in the impact studies used by the European Commission to evaluate the results that could be expected following the adoption of REACH, it was explained that the positive effects on public health would be in the order of 50 billion euros (for a presentation of the various impact studies that preceded the adoption of REACH, see Schuseil 2013). To this could also be added the benefits of innovation if the Porter hypothesis proved to be valid (see Ambec et al. 2013; Arfaoui et al. 2014, for more details on the links between regulation and innovation).

The first paragraph of Article 1 of Regulation No 1907/2006, setting out the political objectives of the strategy proposed by the European Commission in the White Paper, makes clear that REACH has three hierarchical and cumulative objectives: (1) to ensure a high-level protection of human health and the environment, (2) to allow the free movement of substances in the internal

market, and (3) to improve competitiveness and innovation.

Finally, it should be noted that this legislation is one of the main manifestations of the EU's commitment to the plan adopted at the Johannesburg World Summit in 2002, which aimed to ensure that, from 2020, chemicals would be produced and used in a manner that minimizes health and environmental effects.

REACH's Structural Principles

The overall functioning of REACH is based on a single integrated system consisting of four phases: registration, evaluation, authorization/restriction, and controls and sanctions. We will concentrate mainly on the first phase.

To remove the main flaws of the previous system, REACH has, on the one hand, abolished the distinction between existing substances and new substances and, on the other hand, reversed the burden of proof of safety. Thus, as a matter of principle, all substances and preparations must be notified to ECHA by the companies wishing to use them, except for the exemptions referred to in Article 2 (e.g., radioactive substances, medicines, waste), those requested by the member states in respect of their national defense, and the derogations provided for in Annexes IV and V to the Regulation. It is therefore up to the manufacturers, importers, or downstream users of chemicals to provide the authorities with all the information necessary for the demonstration of the absence of effect on the health and environment of the latter.

In the absence of such registration, the manufacture, importation, and use of these products are illegal, as Article 5 states: "no data, no market." Given the particularly substantial dimensions of REACH, the Regulation provided that these obligations would be implemented gradually and with a growing regulatory requirement based on tonnage. The implementation of the REACH registration phase takes place according to the following timetable: (1) before 30 November 2010 for substances produced at more than 1,000 tons per year, (2) before 31 May 2013 for substances produced between 10 and 100 tons per

year, and (3) before 31 May 2018 for substances produced at more than 1 ton per year. Furthermore, REACH requires the existence of a chemical safety report in the registration dossier only for substances produced at more than 10 tons per year.

To our knowledge, the aspect that has received the most attention in terms of registration is information. In order to avoid duplication costs and vertebrate animal testing, REACH has imposed an obligation on manufacturers, with the exception of the derogation until 1 June 2018 (the date of the end of the implementation of REACH), to share the information they have in SIEF (Substance Information Exchange Forum). Three elements emerged that could be problematic: information content, competitive aspects, and financing. We shall now return successively to these three points.

The first was whether the information required by REACH should relate only to risks known with certainty. This issue has been clearly resolved since Article 191 of the Regulation states that the EU's environmental policy is based, *inter alia*, on the precautionary principle. As a result, manufacturers must also take into account the potential risks in their file and indicate which preventive actions they intend to take (on the economic analysis of the precautionary principle, see Gollier et al. 2000).

The second issue was whether companies could not use REACH as a support for anti-competitive strategies (Béal et al. 2011). The most common idea would be to strategically use this sharing of technical information, either to exchange commercial information and thus reach cartels or, on the contrary, to create extremely expensive data to prevent certain firms from remaining in the market by increasing their costs and thereby abusing of a dominant position. Recital 48 and Article 25 of the Regulation recall that the application of the European competition rules remains valid. We are not aware of any infringements relating to possible anticompetitive behavior these last years. This being said, it should be pointed out that the latest general report of the

European Commission (2013, p. 5) stresses that: “The cost of REACH registration has discouraged some companies from competing on certain substances markets, which in these cases have increased market concentration and prices.”

Finally, the third element was related to the financial impact of data sharing, i.e., the question of how to implement a compensation mechanism between the various stakeholders. As an indication, as of September 2007, ECHA proposed a guide which it updated last November (see ECHA (2016)). We can also note, notably thanks to the work of Dehez and Tellone (2013), Béal et al. (2010), Béal and Deschamps (2016), and Béal et al. (2016), that this issue was the subject of a thorough study leading to the conclusion that cooperative game theory offers both a structured discussion path and clear answers depending on the properties desired by the stakeholders.

Lastly, it should be noted that the EU member states operate at a double level to make the regulatory system work, since they are both responsible for providing a national free assistance service for industrialists (art. 124) and also for participating in the controls, inspections, and sanctions of offenders on their territory (art. 126), which resulted in a change in their domestic legal systems.

ECHA (<https://echa.europa.eu>)

ECHA (European Chemicals Agency) has been operational since 1 June 2007 with headquarters in Helsinki, Finland. It employs approximately 600 people and has an annual budget of around 100 million euros. Its main role is to implement, inform, and enforce the European REACH regulations as well as those relating to the classification, labeling, and packaging of chemical substances (CLP, No. 1272/2008), to biocidal products (BPR, No. 528/2012), and to prior informed consent for imports and exports of certain dangerous chemicals (PIC, No. 649/2012).

In addition to its administrative nature, ECHA has the particularity of housing within it a court:

the Board of Appeal. It decides independently on appeals against certain decisions taken by ECHA under the REACH and BPR regulations (on the link between the question of the sharing of data and the Board of Appeal, see Béal and Deschamps 2016). Its decisions, where they are not final, are subject to appeal before the European Union Tribunal and an appeal to the Court of Justice of the European Union.

Socioeconomic Analysis Inside REACH

Socioeconomic analysis (SEA) is used in the REACH regulation either in the context of a request for the use of a substance subject to authorization (Annex XIV) or in the context of a restriction proposal (Annex XVII). In each of these cases, the objective is to assess the costs and benefits to society of the use (or nonuse) of a substance. In its checklist, ECHA distinguishes among five different types of impacts to be taken into account in the context of a SEA: risks to human health, environmental risks, economic impacts, social impacts, and economic impacts. In addition to the cost-benefit analysis, the ECHA guide (2011) recommends the use of multicriteria analysis, cost-effectiveness analysis, compliance cost analysis, and macroeconomic modeling. The use of SEA can be considered to offer two valuable advantages: the transparency of the elements taken into account and a structured framework allowing the consultation of the stakeholders.

Summary

As REACH regulation will completely come into force on 1 June 2018, it is difficult to have a sufficient knowledge on it before almost 2028. Nevertheless, the early stages of implementation have already produced a new European chemical market structure and innovation behavior which have led to new developments in law and economics. We are convinced that for the next 10 years, lawyers and economists will have much to analyze both theoretically and on the application of REACH.

Definition

The incorporation and valuation of operational flexibility and of strategic value of investments in the decision-making process under uncertainty. The option nature of the investment decision arises from the coexistence of uncertainty, irreversibility, and timing flexibility and allows reaping upside potential while insulating from downside risk.

Introduction

The decision to allocate resources to investment opportunities is traditionally evaluated using a net present value (NPV) approach for private sector projects or a cost-benefit approach for public sector projects. Typically, it sums all the incoming and outgoing cash flows over the lifetime of a project, each discounted at an appropriate risk-adjusted discount rate to derive its present value. The latter is compared with the (current) initial investment cost needed to start the project. In case the outcome of this comparison renders a positive result, one decides to invest; in the other case, one rejects the project. While the NPV approach is a very valuable and a beautiful decision tool, its inherent limitations are well documented: it supposes a now-or-never decision and assumes the decision-maker to follow a rigid path once the investment decision is taken (Feinstein and Lander 2002).

In reality, in a dynamic environment with uncertainty and change, projects will often not materialize in the same shape as the decision-maker has initially expected, and he will have to

adjust the initial plans (Cassimon et al. 2004). During the lifetime of the project, new information may arrive or particular sources of uncertainty may be resolved, making it thus valuable to modify the project (Trigeorgis 2000). For instance, market demand for a product remaining below expectations will call for scaling down the project or vice versa; when demand is above expectations, a scale up might be appropriate. However, the NPV or cost-benefit model cannot handle operational flexibilities such as delaying, scaling up, scaling down, shutting down/restarting, or abandoning a project (Guerrero 2007). Moreover, the NPV model cannot handle strategic dimensions of projects either (Kester 1984). This is the case when different investment projects are not independent of each other or when one specific project consists of different interconnected phases (Dixit and Pindyck 1994). A classic example is research and development (R&D). If a decision-maker would rigidly apply the cost-benefit rule to an R&D project, he would never implement it as its NPV *as a stand-alone project* would be negative. However, in reality many companies nevertheless invest in R&D. This illustrates the limitations of an NPV framework. Such capital budgeting decisions are better handled using a real option framework (Trigeorgis 2000).

This contribution will show that the optional nature is valuable in an investment environment characterized by the simultaneous existence of uncertainty, irreversibility of investment, and some freedom on the timing of the investment (Pindyck 1988). The added value of a real option approach lies in the fact that decision-makers focus more explicitly on proactively considering operational flexibilities or strategic aspects embedded in investment opportunities, rather than making a now-or-never decision to rigidly implement a project as initially planned (Trigeorgis 1996). Moreover, it also allows them to put a precise value on these flexibilities or strategic aspects. As such real option models are an important tool to replace soft decision-making based on vague and qualitative factors, which leave decisions more open to erroneous or manipulative outcomes.

Financial Options and Analogy with Real Options

Recognizing the project itself or particular features of a project as having option characteristics is therefore the key to applying insights of real option modeling. In general, an option can be defined as the right, but not the obligation, to buy (in that case it is labeled a call option) or sell (in that case it is labeled a put option) the underlying asset at an agreed price (strike price or exercise price) during a specific period (as in the case of American options) or at a predetermined expiration date (as in the case of European options) (Hull 2011). Financial options exist on shares, on stock indices, on bonds, on currencies, and on many other financial assets.

For instance, a share of Apple Inc. is trading at \$93.50 in the market. A European call option on one stock of Apple with an exercise price of \$100 and expiration date in 3 months would cost about \$2.40 today. This call option gives the holder the right to buy one share of Apple on the expiration day at \$100. Whenever the share price at expiration is higher than the exercise price, the holder will make a profit by acquiring the share through exercising the option (at \$100) and selling it at the higher market price at that moment (e.g., \$120). In case the share price ends below the exercise price, the holder will not exercise the option and let it expire. Figure 1 shows the typical payoff profile of a European call option at expiration. In this way the holder of the option shields off negative share price evolutions while benefiting from positive share price movements. For having this luxury, the holder pays the option premium of \$2.40 at the option exchange. If the call option was of the American type instead of the European type, the holder can exercise the option earlier than the expiration date. Cassimon et al. (2007) discuss under what conditions these call options will be exercised earlier.

In contrast to financial options, real options refer to the application of the option concept to real physical investment opportunities. Any decision to go ahead with an investment project can be viewed as exercising an option, whereby the firm has the right to obtain all the underlying cash flows that are resulting from the investment

Real Options, Fig. 1 The payoff profile of a European call option at expiration (excluding option premium)

Real Options, Table 1 Analogy of the value drivers of financial and real options and the impact of option value

Symbol	Financial options	Real options
V	Underlying asset price	Present value of the expected cash flows
I	Strike price	Investment costs
σ	Volatility of underlying asset return	Volatility of underlying project return
T	Time to maturity	Window of opportunity
r	Risk-free rate	Risk-free rate
δ	Amount of dividend payments	Opportunity costs of not exercising the option

project (the so-called value of the project, with symbol V), at a particular known cost (the investment cost, with symbol I); the latter is analogous to the exercise price in financial options. When the firm decides to go along with the investment project, it executes the option. In this way, one can draw a parallel between the structure of financial options' payoffs and the payoffs a firm or investor can obtain from a real investment project. Consequently, the argument is made that fundamental value drivers of financial options are also relevant for the valuation of real investment projects. Table 1 gives an overview of the basic value drivers of financial options and the corresponding variables in real investment projects. Apart from the two determinants that drive also the NPV (as the NPV equals $V-I$), note that the other parameters explicitly account for characteristics that embed flexibility and strategic considerations: the fact that future returns are uncertain, the fact that there is some leeway in timing the investment

decision, and the fact that returns may be foregone as long as the project is not yet started.

Basic Option Models

The valuation models for real options are based on financial option models. Probably the best-known model has been developed by Black and Scholes (1973). Its popularity is derived from its closed-form solution and fast and relatively simple computation. Its main disadvantage is due to the strict assumptions underlying the model: (i) frictionless markets, implying no transaction costs or taxes, nor restrictions on short sales; (ii) continuous trading is possible; (iii) the risk-free (short-term) interest rate is constant over the life of the option; (iv) the market is arbitrage-free; and (v) the time process of the underlying asset price is stochastic and exhibits a process assuming asset prices to be log-normally distributed and returns to be normally distributed. Obviously, any violation of some of these assumptions may result in a theoretical Black-Scholes option value which deviates from the price observed at the market. The option value C according to the Black-Scholes model can be calculated as

$$C = V e^{-\delta(T-t)} N(d_1) - I e^{-r_c(T-t)} N(d_2) \quad (1)$$

$$d_1 = \frac{\ln\left(\frac{V}{I}\right) + \left(r_c - \delta + \frac{1}{2}\sigma^2\right)(T-t)}{\sigma\sqrt{T-t}} \quad (2)$$

$$d_2 = \frac{\ln\left(\frac{V}{I}\right) + \left(r_c - \delta - \frac{1}{2}\sigma^2\right)(T-t)}{\sigma\sqrt{T-t}} \\ = d_1 - \sigma\sqrt{T-t}, \quad (3)$$

where V is the present value of the project's future operating cash flows, I the exercise price or the project's capital expenditure, $T - t$ the time to expiration (in years), σ the annualized standard deviation of the project return, r_c the continuous risk-free interest rate, δ the opportunity cost of waiting, and $N(d)$ the cumulative normal probability density function.

A more practical model that is often used in applications is the binomial option valuation model. This model assumes that in every time period Δt , the stock price moves either upward with factor u or downward with factor d , with $u = e^{\sigma\sqrt{\Delta t}}$ and $d = 1/u$ (Cox et al. 1979). One then has to determine the tree of future stock prices one is going to use as an approximation for future stock price evolutions. For instance, if time to expiration $T - t$ is 1 year and one uses 250 tree steps n , then the stock moves up or down every $\Delta t = \frac{T-t}{n} = \frac{1}{250}$ or approximately 1 step equals 1 trading day. In this case, the binomial model calculates the current option value by discounting at each node of the tree the upward and downward expected option values:

$$C = \{[C_u \times p] + [C_d \times (1 - p)]\}e^{-r} \quad (4)$$

where C is the current option price, C_u is the expected option value in the upward world, C_d the expected option value in the downward world, p the risk-neutral probability that the stock moves upward with $p = \frac{e^r - d}{u - d}$, and r the risk-free interest rate.

Often more complicated option models are needed to handle the specific nature of the investment opportunities and/or the nature of embedded uncertainty. Such models include jump models (Merton 1976), compound option models (Cassimon et al. 2004), or barrier models (Engelen et al. 2016). A detailed discussion of these models is beyond the confines of this contribution, but we refer the reader to the references for further details.

Different Types of Real Options

Different theoretical types of real options have been developed in the early literature: options to

delay (McDonald and Siegel 1986), growth options (Amran and Kulatilaka 1999), options to abandon (Myers and Majd 1990), or scale options (Trigeorgis and Mason 1987). This section starts by discussing the investment "timing option" (or option to delay). Next, we analyze "growth options" (single stage) or "sequential options" (multiple stages) which open up new options upon exercise. This type of option is important when investments are needed to develop new technology or open up new markets. A fourth type we distinguish is the "option to abandon" the project at salvage value. Finally, there are a series of "operational flexibility options," including the flexibility (at some additional cost) to scale up (expand), to scale down (contract), to stop and restart operations, or to switch to other inputs or outputs in response to market and cost developments; each of them can be valued correctly using a real option framework.

Option to Delay

The option to delay (or wait) focuses on the optimal investment timing. It examines whether a company should implement a project right now or better postpone the investment for x months/years before taking the investment decision. The advantage of waiting is that it allows a company to avoid being stuck in an irreversible loss-making investment if project conditions move in an unfavorable way (Ingersoll and Ross 1992). During the period of waiting, the company can learn or collect more information about sources of uncertainty to take a better informed decision at a later point in time (McDonald and Siegel 1986).

Consider an investment project with an economic life span of 15 years, and it is expected to yield every year free operating cash flows of 120 million euro. To enter into this investment opportunity, the firm has to pay an initial investment expenditure of 800 million euro. The company's cost of capital is 10%, while the risk-free interest rate amounts to 5%. The uncertainty of the market demand for these products, as measured by the standard deviation, is estimated to be 30%. Suppose, management wants to know whether to invest in this project immediately or to postpone the project with 1 year (during which

more information concerning the profitability of the project becomes available). This is an example of an option to delay. According to the traditional NPV rule, this is a valuable project which should be implemented immediately. For, the NPV amounts to $\sum_{t=1}^{15} \frac{120}{(1,10)^t} - 800$ or 112 million euro.

Does real option analysis yield a different result? If the decision is postponed for 1 year, this option to delay has a value of 133 million using a binomial option model with 250 tree steps. To come to this figure, we used the following input parameters: the present value of the cash flows from year 2 to year 16 being 829.75 (V), the investment outlay of 800 (I), the option's time to maturity of 1 year ($T - t$), volatility of 30% (σ), and the risk-free interest rate of 5% (r_F). Calculations can be checked through Derivagem (2014).

Because the real option value (measuring the value of delaying of the investment) exceeds the NPV (measuring the immediate investment value), it is better for the firm to postpone the decision with 1 year instead of investing immediately. In 1 year time, the firm can take a more informed decision. Note that delaying investments is not always possible. Also, firms will invest earlier when there is some opportunity cost of waiting (the parameter δ) such as losing market share or the loss of first-mover advantages. Any opportunity costs by waiting have to be deducted from the real option value. If in our example opportunity costs are estimated to be 30 million euro, the real option value is only

103 million, reversing the company's decision as investing immediately will yield a higher value of 112 million euro.

Growth Option

Growth options occur when projects consist of two phases or stages. The first stage is a prerequisite in order to be able to consider the following phase. Take, for instance, a project that is in fact a pilot scheme for a large-scale project. It is clear that this pilot scheme has option characteristics. The large-scale project can only be considered when the firm has indeed decided to execute the pilot phase (see Fig. 2). However, in case the pilot phase turns out to be a failure, the company does not move to the second phase and just terminates the project (Cassimon et al. 2011b). As such, the pilot phase gives the firm a call option on the large-scale project. The investment cost of the large-scale project and the additional future cash flows that result from it are the execution price, respectively, and the underlying asset of the option (Kester 1984). The value of this call option should be taken into account when calculating the value of the pilot phase, by adding this option value to the conventionally calculated NPV of the pilot phase. It might well be the case then that projects, which would be rejected on the basis of a negative NPV, are now worth executing due to their option value. If the sum of the growth option and the net present value of the pilot phase is positive, it is therefore rational for the firm to invest in the pilot project as the entire project has enough upside

Real Options,

Fig. 2 Typical profile of a growth option

potential to compensate for the (likely) initial losses in the pilot phase. In the other case, the pilot project (and thus the entire project) should be rejected. Investors care about the value drivers of the growth option as well as the pilot project itself.

An example of a growth option is a US home decoration chain exploring the possibility to enter the French market. In order to explore the market potential for their product, the company decides to launch a pilot project with a cost of 110 million euro and 100 million euro expected net operating cash flows in present value terms. It is obvious that the pilot project as a stand-alone project is loss-making (−10 million euro) and should be rejected following the NPV criterion. However, if successful, assume the company plans to launch a large-scale commercialization project opening dozens of megastores across France. The follow-up project is expected to be launched after 2 years at a cost of 200 million euro. At this moment the present value of the operating cash flows of the follow-up phase is estimated to be 180 million. Although the present value of the cash flows is still lower than the investment cost at this moment, things could change over time. The volatility of project returns in this industry is estimated to be 25% per year. The risk-free interest rate is equal to 5%. Using a binomial model with 250 tree steps, the option value of the follow-up phase amounts to 25 million euro. Compared to the value of phase one of −10 million, it makes sense to invest in the pilot project as there is enough upside potential to justify investment. The total project value comes to $-10 + 25$ or 15 million euro. Whether the company will actually invest in phase two is only decided at the end of year 2 and will depend on the market conditions at that moment. For the moment, the company only commits itself to the pilot project, with the possibility for expansion at the end of year 2.

Sequential Option

When a growth option involves more than two phases, one has to enlarge the standard option approach to so-called sequential options, which can be valued using compound option techniques (Cassimon et al. 2011a). The option value of the

second phase includes in this case also the option value of the subsequent phase. Put differently, in that case we have an option on an option or a compound option (Geske 1979).

A copybook case of a sequential option is the development of a new drug. A drug development pipeline consists of six distinct and specific phases (see Fig. 3). Developing a new drug is a chain of options starting with a preclinical test phase, followed by three clinical test phases, a governmental approval phase, and ultimately the commercialization phase. The initial R&D phase can be seen as an option on the preclinical test phase. If the initial R&D turns out to be successful, the preclinical phase is started; otherwise the research is being discontinued. The preclinical phase itself is an option on the first clinical test phase. If the preclinical tests are successful, the compound moves to the first clinical test phase; if not, the research is again abandoned. This phase is again an option on the next phase and so on, until the commercialization phase. This is a heavily regulated, standardized, and linear process because each phase is easily identified and has to be finished before the next phase can start. The initial R&D phase, being a sixfold compound option on the commercialization phase, can be valued using a generalized compound option model, such as the one by Cassimon et al. (2004), that was explicitly developed to value compound options of a higher order than two.

Option to Abandon

If market conditions deteriorate, management can also consider terminating and abandoning the project permanently. Having the option to realize a certain salvage value puts a floor to the potential losses of a project and thus adds value in comparison to the same project without this possibility. Management compares the project value as a going concern with the liquidation value the firm can realize upon termination of the project. This managerial decision can be interpreted and valued as a “put option,” the right to sell an asset at a predetermined price at or up to a predetermined point in time (Myers and Majd 1990). The value of this put option should then be added to the project’s traditional (NPV-type) value.

Real Options, Fig. 3 The development of a new drug as a sequential option

Operational Options

Operational options include options to expand, contract, suspend, and resume operations and the option to switch inputs or outputs during operation (Brennan and Schwartz 1985; Dixit 1989; Kulatilaka and Trigeorgis 1994). An example of a switch option is a chemical factory that builds in flexibility at the input or output side. At an additional cost, a company can decide to add input flexibility by building a factory that can switch from one energy source (say oil) to another energy source (electricity or gas). It allows companies to switch to cheaper energy sources during the project. This flexibility comes at a cost, which has to be compared with the value of the switch option. The company can also build in flexibility at the output side by building a factory that allows for various output products, e.g., switching from producing polyvinyl chloride (PVC) to polypropylene (PP) or polyethylene (PE). Again, balancing the value of the switch option to the

additional cost of building a flexible factory is at the core of the real option framework.

A shutdown and restart option assumes that a project does not have to be operated permanently. Depending on the net revenues and (marginal) costs, management can temporarily suspend operations and resume once net revenues again cover the (variable) cost of operation. In option terms, this means that management has the option to receive the project's net revenues minus the variable costs when the project is operated in a given year (Trigeorgis 2000). The value of the project in any given year is thus the maximum of that year's cash revenues minus that year's variable costs of operation or zero. Put differently, the project will be operated if and only if the revenue exceeds the variable costs. This limits the downside risk to the fixed costs, and therefore the project value should respond positively to increasing volatility in variable costs and in operating cash flows. Intuitively, all else equal, in more volatile environments, the

value of operational flexibility is higher (Sanders et al. 2013).

The option to scale up (expand) can be seen as a call option in a similar way as a growth option, while the option to scale down (contract) can be seen as a put option similar to an option to abandon.

Measuring Risk

One feature that all real option models have in common is that they require the input of an estimate of one or more sources of risk (proxying for uncertainty). In this contribution we focus on market risk (also labeled commercial risk) and technical risk.

Market Risk

Market risk is measured as the volatility of the project return between the current moment and the expiration date of the real option. It measures how much the project value, measured as the present value of all expected operating cash flows in the final phase (V), will vary over time. Real options only have value when things can change over time. The higher the volatility, the higher the change that tomorrow's world will materialize differently from what the decision-maker had in mind today. The estimation of the future volatility can be difficult when the amount of available data is limited. Sometimes nothing more than an educated guess is used. A "normal" range for volatility is about 30–40%. Often an educated guess is good enough as an input, especially if changes in volatility have little impact on the investment decision. Applying real option thinking compared to traditional valuation methods is often the key element; fine-tuning the volatility estimate often does not add a lot to insights. Sometimes a more precise estimate is required as the investment decision alters depending on the level of the volatility estimate. Cassimon et al. (2011a) give an overview of different proxies for volatility. A first approach is to use historical volatility derived from historical market data such as oil prices, commodity prices, real estate prices, and so on. A second approach uses volatilities of a sample of comparable firms. A third approach is the calculation of the implied volatility of options on a

comparable firm as a proxy for the future volatility (Schwartz and Moon 2001). Finally, the use of internal company data is sometimes a good strategy. It is a viable approach if the firm has a portfolio of past and current projects, considered to be representative for the risk profile of the current project.

Technical Risk

While market risk, as captured by the volatility of the project return, refers to the normal business risk any company incurs, such as the potential market size, its expected revenues, its expected cost structure, and so on, technical risk refers to a catastrophic event (technical failure) that terminates the project and is unrelated to its cost or benefits. For instance, the uncertainty about the effectiveness or about potential problematic side effects of a new drug is an example of technical risk (Cassimon et al. 2011a). Such technical failure is the type of uncertainty that presents itself as a negative shock to the project value. Technical risk can be captured by a Poisson process (in case the nature of uncertainty is best characterized by discrete jumps) or by using discrete success-failure probabilities at each stage of the project.

Applications

Applications in General

Real option models to project evaluation are applied in a wide range of sectors, such as Internet companies (Schwartz and Moon 2001), the service sector (Jensen and Warren 2001), consumer electronics (Lint and Pennings 2001), pharmaceutical R&D (Cassimon et al. 2011a), the ICT sector (Cassimon et al. 2011b), and sustainable energy solutions (Sanders et al. 2013; Engelen et al. 2016).

Applications in Law and Economics

Some law and economics studies apply real option reasoning to enrich static models on modeling agent's behavior. For instance, Engelen (2004) extends the classic Becker expected utility framework on criminal behavior to provide a more dynamic decision-making framework of criminal activity. While conventional models of crime

focus on the expected net gain of a crime as the difference between the expected profits of a crime and the expected costs (i.e., the product of the amount of punishment and its probability (Engelen et al. 2016)), such a framework ignores the simultaneous existence of uncertainty, irreversibility of the criminal act, and flexibility in the timing when to commit the crime. If those characteristics are present, a criminal can delay committing the crime until more information about the uncertain future becomes available. Waiting some time to commit the crime might imply some risks and foregone profits, but it may prevent the criminal from being trapped in an irreversible crime, which may turn out to be very costly when being caught. Engelen (2004) shows that a crime that satisfies these three characteristics is best treated analogous to holding a financial call option. For some specific time period, a criminal has the possibility, but not the obligation, to pay a certain “price” in return for an asset that has some value. When the criminal decision is made, the option is exercised, which is an irreversible decision.

Cassimon et al. (2013) apply a criminal real option framework to criminal states. They study two episodes of criminal behavior by Rwanda in the Democratic Republic of Congo (DRC): the massive killing of Hutu refugees by the Rwanda Patriotic Army (RPA) in late 1996 to early 1997 and the illegal exploitation of Congolese resources from August 1998. They show how the international community can optimally intervene proactively, by reducing the incentives for criminal states to execute their criminal options.

While the above studies focus on handling uncertainty from an agent’s point of view, other studies use real option modeling from a lawmaker’s point of view. Deffains and Obidzinski (2009) apply the real option approach to the design of legal rules. Rulemakers face the choice between rule-based regulation and standard-based regulation. Detailed rules provide clear guidance to agents but are more costly to create ex ante and risk to become obsolete over time as market conditions vary. Standards are more flexible as they allow to adapt regulation more easily to the changing environment, but they are more costly in court

interpretation ex post as interpretation is more ambiguous. A real option framework shows that this choice depends on the variability of contingencies and on the degree of innovation in the area of the law. Adding the timing dimension and uncertainty to the classic trade-off between rule and standard allows to move from a static to a more dynamic perspective which is closer to real-life decision-making. In a similar vein, Parisi et al. (2004) analyze the value of waiting in lawmaking. Waiting to enact a certain law while collecting more information can be a better choice than being stuck in an ineffective or undesirable rule.

Lee et al. (2007) analyze the impact of bankruptcy law on entrepreneurial risk taking through a real option lens. They argue that society will benefit from more entrepreneur-friendly bankruptcy laws. Speedy bankruptcy procedures, discharging bankrupt individuals from debt, and automatic stay on assets will allow inefficient firms to exit more easily and will encourage potential entrepreneurs to enter the market without having to be afraid of the damaging consequences of a possible bankruptcy. Using a real option perspective, this study clearly shows the impact of the design of legal rules on entrepreneurial activity at the societal level.

Abstract

Regulatory competition describes the activity of private or public lawmakers who intend to produce novel or alter current legislation in response to competitive pressure from other private or public lawmakers. In this chapter, we provide an overview of the legal arbitrage tactics of various entities, which are a necessary, though not sufficient, condition for

regulatory competition. Moreover, we investigate whether and how lawmakers respond to these endeavors by adapting their national corporate, insolvency, capital markets, and environmental law as well as product standards.

Defining Regulatory Competition

Regulatory competition describes the activity of private or public lawmakers who intend to produce novel or alter current legislation in response to competitive pressure from other private or public lawmakers (Hornuf and Lindner 2016). It is often private lawmakers, nation-states, regions, communities, and supranational organizations that engage in such competitive processes.

The literature distinguishes two forms of regulatory competition. First, Tiebout (1965) outlines a theoretical framework in which lawmakers offer a package of goods and services to legal entities under their jurisdiction. These legal entities can be individuals, companies, or other organizations recognized by law. In return for this package of goods and services, legal entities make tax payments. Unlike lawmakers, legal entities are mobile and spur the competitive process by physically moving to regions where legislators offer the best bundle of goods and services. Companies usually do this by moving their headquarters or by investing in production sites in the respective region. Typical bundles offered by lawmakers may encompass a certain physical and legal infrastructure, the latter of which includes, for example, specific taxes; corporate, bankruptcy, and environmental laws; and product safety and labor market standards.

Second, regulatory competition can also arise from unbundling certain legal rules from the physical location of a legal entity (Heine and Kerber 2002; Eidenmüller 2011). A possible constellation would be when a company locates its headquarter in the United States, adopts the company law of England and Wales, finances projects with debt securities under the law of the Cayman Island, and settles disputes in a Swiss court under French law. If the choice of law is independent of the physical location of a legal entity, this

allows individuals and companies to cherry-pick the rules that are most suitable for their respective business transaction. Moreover, from an economic perspective, lawmakers that engage in this type of regulatory competition can better specialize in certain legal products and do not need to offer a complete bundle of laws to their customers.

The welfare implications of regulatory competition have been subject to a long-standing dispute in the law and economics literature. Most prominently, they were debated in the field of corporate law as unbundled competitive processes. While some scholars have persistently claimed that regulatory competition leads to the implementation of optimal legal rules, also known as the *race-to-the-top* hypothesis (see Winter 1977; Fischel 1982; Romano 1987), others have argued that regulatory competition leads to the prevalence of the lowest respective standards, also referred to as the *race-to-the-bottom* hypothesis (see Cary 1974; Bebchuk and Hamdani 2002). From a multi-level perspective, Sinn (1997) theoretically argues that when government regulation serves a purpose such as to overcome market failure and later becomes subject to competition on a higher regulatory level, regulatory competition again leads to economic inefficiencies.

Regulatory Competition in Corporate Law

In corporate law, conflict-of-law rules define whether legal arbitrage by companies in the respective jurisdictions is possible, which is a necessary, though not sufficient, condition for regulatory competition. Legal arbitrage can be understood as a legal planning technique that is carried out to avoid taxes and other legal rules to circumvent regulatory costs (Fleischer 2010). At the national level, legislators can apply either the real seat theory (*siège réel*) or the incorporation theory when dealing with foreign companies. After World War II, the real seat theory was most prevalent in Western Europe, practically prohibiting a free choice of law independent of corporate headquarters. Nevertheless, the mobility of companies has been a cornerstone of the

Single European Market, leading the European Court of Justice (ECJ) to interpret Art. 49, 54 TFEU (formerly Art. 43, 48 EC Treaty and, before that, Art. 52, 58 EEC), regarding cross-border company mobility. Starting with the *Daily Mail* (Case C-81/87, 27 September 1988) in 1988, the ECJ had largely abolished the real seat theory by the turn of the millennium, with the famous decisions on the *Centros* (Case C-212/97, 9 March 1999), *Überseering* (Case C-208/00, 5 November 2002), and *Inspire Art* (Case C-167/01, 30 September 2003) cases.

Regarding inbound cases, in which a foreign company seeks to immigrate into a certain jurisdiction, the ECJ found that companies registered under the law of their home member state had the right to transfer their head office to another member state. Unlike before, this could now be achieved without liquidating the original company and reestablishing a new legal entity. Consequently, the host member state must recognize the foreign company, which does not need to meet standards such as the minimum capital requirement for incorporation in this country. The founder of a company can thus choose a company law that best suits the business needs independent of the company's real seat. This rule largely paved the way for regulatory competition in the European Union (EU). Conversely, companies that intend to emigrate are still restricted by national legislation, as member states still have the power to prohibit such outbound cases. According to ECJ's *Daily Mail* (Case C-81/87, 27 September 1988), *Cartesio* (Case C-210/06, 16 December 2008), and *National Grid Indus* (Case C-371/10, 29 November 2011) decisions, home member states can require companies to have their registered office and head office under the national law of the respective territory. Otherwise, the company may need to be dissolved. Finally, the ECJ recently enabled existing companies to move their statutory seat to another jurisdiction in the *Cartesio* (Case C-210/06, 16 December 2008) and *VALE* (Case C-378/10, 12 September 2012) decisions of 2008 and 2012. Although such a transfer of the registered office necessarily leads to a conversion of the company into a company governed by the law of the new

member state, the company no longer must be dissolved.

How did national lawmakers react? Since 2003, not less than ten major company law reforms have been implemented in nine EU member states (Hornuf and Lindner 2016). Lawmakers in France (in 2003 and 2008), Hungary (in 2007), Germany (in 2008), Poland (in 2008), Denmark (in 2010), Sweden (in 2010), and the Netherlands (in 2012) were forced to reduce the minimum capital requirement for national legal forms, and many of these jurisdictions abolished the minimum capital requirement altogether. Seven years after the initial reform, Hungary decided to raise the minimum capital requirement back to the initial level. In some cases, lawmakers introduced a new legal form, abolished the notary requirement for setting up a company, or allowed for electronic company registrations and document filings. In almost all cases, the administrative speed of incorporation was increased. These factors were previously found to be the main drivers of legal arbitrage (Becht et al. 2008), and thus regulatory reforms might be considered a response to the competitive pressure exerted, mostly by the English Limited. Braun et al. (2013) show that the reduction of the minimum capital requirement helped countries not only improve the attractiveness of the national legal form but also increase entrepreneurial activities in general.

Unlike in Europe, where regulatory competition might also be driven by the pride of national lawmakers to offer the "regulation of choice," which fosters a prosperous private legal industry, the main objectives for US lawmakers to engage in regulatory competition and to create new company law rules is the ability to raise charter fees. Recently, approximately two-thirds of *Fortune* 500 companies and more than four-fifths of all new US initial public offerings chose to incorporate in Delaware (Bullock 2013). Although evidence shows that companies not incorporating in Delaware are subject to a home-state bias (Bebchuk and Cohen 2003), Delaware still collects approximately one-fourth of its overall tax revenues through business entity taxes and fees as well as Delaware Uniform Commercial Code fees (Bullock 2013). In Europe, such financial

incentives to engage in regulatory competition do not exist as the collection of charter fees is generally prohibited by EU legislation.

Not only does regulatory competition in corporate law take place *horizontally* between different US states or European nation-states, but it also occurs *vertically* between, for example, Canadian provinces and the federal lawmakers or national legislators and the supranational EU. In Europe, a supranational corporate law form was established with the Statute for a European Company (*Societas Europaea*, SE). Importantly, the European Company did not provide a full company law but rather refers some material matters to the national corporate law of the member states. Here, the scope for legal arbitrage emerges. While companies might adopt the European Company for various reasons, early evidence indicates that companies may choose the SE to freeze or renegotiate mandatory codetermination as well as to establish a one-tier board structure, especially if that was not possible under national corporate law (Eidenmüller et al. 2009). Fierce vertical regulatory competition in corporate law did not emerge until more recently. After reviewing the SE Statute in 2012, the European Commission noted that any benefits of a reform would not outweigh the potential challenges. Consequently, there was no intent to improve the competitive stance of the European Company. The proposal of a European private limited liability company (*Societas Privata Europaea*, SPE) faced opposition by some member states early on and so far has not been approved by the Council of the European Union.

Regulatory Competition in Insolvency Law

Insolvency laws in the EU are not harmonized; rather, individual jurisdictions keep their own national rules and proceedings. As a result, legal arbitrage activities of consumers and companies can theoretically spur regulatory competition. In the realm of personal insolvencies, consumers may shop, for example, for a shorter statutory discharge period. The discharge period can range

from under 3 years in countries such as France, Latvia, Poland, or England and Wales and increase to at least 5 years such as in Austria and previously Germany (Drometer and Oesingmann 2015). Other variations in the insolvency regime concern the right of debtors to prevent a discharge because of misconduct on the borrower side, which may exist in some jurisdictions but not in others. From an economic perspective, shorter discharge periods spur consumption and support individual risk taking. By contrast, the prospects of a discharge also increase the moral hazard problem and weaken credit discipline (Adler et al. 2000). During the past decades, reforms in consumer insolvency laws did not, however, solely result from lawmakers engaging in regulatory competition; they are also a consequence of the growing over-indebtedness of consumers in general.

As in the case of personal insolvencies, a corporate insolvency proceeding under European rules is opened under the law of the debtor's center of main interests (COMI). According to the latest Insolvency Regulation Recast, the COMI is the place where the debtor conducts the administration of its interest on a regular basis and which is ascertainable by third parties. Given that almost one-fourth of the approximately 200,000 companies that experienced insolvency in Europe between 2009 and 2011 engaged in cross-border activities, some leeway emerged for them to engage in forum shopping. That companies indeed attempt to engage in forum shopping was prominently shown by the insolvency proceedings of Deutsche Nickel and Schefenacker. The head office of both companies was historically based in Germany; however, by merging or selling the company (partly) to a legal entity under English law, both companies attempted to move their head offices to Great Britain to start an insolvency procedure under English law. Under English rules, creditors can, for example, choose an insolvency administrator of their liking and benefit from extended procedural deadlines, and creditors do not need the consent of the previous owners to swap debt to equity. To the best of our knowledge, this form of legal arbitrage did not become a mass phenomenon, partly because of

legal uncertainty about whether such a move of the company seat is legitimate. While legal reforms in insolvency laws have recently taken place, there is no clear-cut evidence that they were the result of regulatory competition.

In the United States, lawmakers established a single federal bankruptcy code. Nevertheless, some scholars argue that judges still have a sufficient leeway to develop a state-specific approach to bankruptcy law (Skeel 1998) and that courts can apply state law, for example, to determine the fiduciary duties of managers (Skeel 2000). Moreover, LoPucki (2006) claims that judges are often motivated by the glamor of dealing with insolvencies of well-known companies, which brings about a better standing for them in the legal community. Moreover, bankruptcy bars exert pressure, which resulted in business activities moving to New York and Delaware (LoPucki and Kalin 2001). As only minor differences exist in the US bankruptcy code, forum shopping is often limited to large borrowers and Chapter 11 prepackaged bankruptcies (Enriques and Gelter 2007), in which debtors offer a plan to creditors, who then vote in its favor before a bankruptcy case is filed with the court.

Regulatory Competition in Capital Markets Law

Capital markets have unique features that facilitate regulatory competition (Ringe 2016). On the one hand, capital markets are essential for many economic activities and thus put substantial pressure on regulators to provide efficient laws. On the other hand, regulatory competition in capital market law emerges not only from issuers deciding for one regulatory regime from a range of options but also from issuers' cross-listing their securities in different markets across different jurisdictions. For example, a company in Angola could issue securities on the new Angola Stock Exchange and have additional disclosure standards imposed by the New York Stock Exchange. The number of companies listing securities outside their place of incorporation as well as the number of cross-listings has grown significantly, which has

resulted in increased competition between stock exchanges in the United States and Europe (Kim and Pinnuck 2014). A frequently mentioned reason for companies to cross-list is the so-called legal bonding to more rigorous disclosure standards to improve access to capital, which in turn lowers the cost of capital and increases the value of a company (Doidge et al. 2004). Coffee (2002) provides a detailed summary of research on the bonding theory.

The main challenge for lawmakers in formulating adequate regulatory instruments in the financial sector comes from the threat of negative consequences for financial stability (Ringe 2016). Thus, a global effort was made to achieve financial stability and has resulted in widespread attempts of harmonization. Worldwide, the most prominent example is the process of harmonizing banks' capital requirements by the Basel Accords of the G20 group. Moreover, in the aftermath of the financial crisis, the EU and its member states have strengthened capital market regulation as well as supervision and prioritized regulatory convergence over regulatory competition in the financial sector. The Capital Markets Union, a recent initiative of the European Commission, aims to create a single market for capital across all EU member states by removing barriers to cross-border investment. Against the backdrop that issuers want to reach capital providers, investor protection regulation also plays a central role in harmonizing capital markets law. For example, the European Markets in Financial Instruments Directive is a strong step forward in converging regulation regarding securities trading in the EU.

As in the other domains, the question has been raised whether regulatory competition in capital market law is likely to yield a race to the top or a race to the bottom. In line with the legal bonding theory, substantial evidence shows that countries with more disclosure requirements and more stringent corporate governance rules provide a more attractive capital market environment with lower cost of capital for listed companies (Prentice 2002). This should motivate countries to raise their disclosure and governance standards to attract more company listings. However, Prentice (2005) notes that in capital markets, no true

competition emerges and that a race to the bottom is more likely because the choice of listing is not made by companies but by self-interested managers. In addition, some scholars focus on regulatory competition among security exchanges and note that this competition does not necessarily yield a race with respect to listing standards but will more likely result in an endogenous segmentation of the capital market for listings with first-tier and lower-tier market segments (Chemmanur and Fulghieri 2006).

Regulatory Competition in Environmental Law

From a political economy perspective, environmental policy making results from the interaction between lawmakers and various interest groups. These interest groups demand different environmental measures and put pressure on lawmakers to decide in their favor (Oates and Portney 2003). For example, voters who call for stricter pollution regulation can threaten governments to withdraw their support during the next election. In this context, the debate also targets the extent to which the implementation of new regulatory instruments is influenced by well-organized interest groups, such as producers and consumers.

Yet, taking international trade into account, it is argued that when states are confronted with economic competition, they have an incentive to adopt lax environmental standards to attract companies and capital, which leads to a race to the bottom of environmental standards (Engel 1996). Regulatory competition would then result in a reduction of environmental protection efforts to the level of the least stringent state. One main reason for this trend is the presence of excessive market power of the industry (Engel 1996).

However, there is no clear indication that environmental regulatory competition necessarily leads to the lowest possible standard to prevail. There might also be a weaker form of the race-to-the-bottom tendency, in which only some states lower their environmental standards under the competitive pressure, and thus not all states converge to the least stringent state (Konisky 2007).

Moreover, Vogel (1997) postulates that the existence of more stringent environmental standards in one country could even trigger a race to the top as companies in other countries want to export their goods and services to the high-standard country and thus must adopt the more stringent environmental standards (the so-called California effect). To avoid the costs of double regulation, companies might lobby their governments to regulate specific environmental issues in accordance with the high-standard countries that exports target. Indeed, an empirical investigation shows that even before the EU adopted a directive regarding a specific environmental regulation instrument, a diffusion process had begun, kicking off a race to the top among member states (Holzinger and Sommerer 2011).

Finally, more environmental standard setting is implemented and harmonized at the international and supranational level. This can be expected to further increase, for example, under the auspices of the United Nations' Paris Agreement, in which 195 nations agreed to undertake ambitious efforts to combat climate change. With accelerating internationalization of environmental regulation, the opportunities to differentiate and compete between single regulators might vanish. Heyvaert (2013) argues, however, that sufficient scope for decentralized regulators remains to implement differential environmental regulation, particularly because only few international environmental standards are truly global and there is also flexibility within transnational regimes.

Regulatory Competition in Product Standards

Consumers are directly affected by regulatory competition when it comes to product standards. Building on Akerlof's (1970) theory of adverse selection, Sinn (1997, 2003) argues that consumer markets are characterized by information asymmetry between consumers and sellers because consumers cannot fully elicit product qualities. This is especially relevant for products whose quality is not likely to be detected because they are not frequently purchased or their value is too

low to justify intensive information gathering. This information asymmetry can lead to low-quality equilibrium in which informed sellers oversupply low-quality products and undersupply high-quality ones. To reduce the negative consequences of such market failures, regulators specify minimum product standards.

Thus, governments intervene where markets have failed. Yet regulatory competition can emerge as countries engage in protectionist practices by undercutting product standards of competing countries to give their own industries a competitive advantage. According to Sinn (1997), the erosion of product standards could follow this activity and reduce consumer protection. In this vein, the recent effort in implementing international trade and investment partnerships across the world is of particular importance. Free trade agreements such as the Transatlantic Trade and Investment Partnership promise strong positive welfare implications through the repeal of non-tariff barriers and the harmonization of standards that act as barriers to trade. However, in particular the harmonization of quality standards resulted in public uprising because people feared that the new product standards could not meet previous national consumer protection preferences.

In the EU, a new era of European competition began with the *Cassis-de-Dijon* (Case C-120/78, 20 February 1979) decision (Sinn 2003). The ECJ held that a regulation applying import restrictions to a product legally produced in one of the EU member states was an unlawful restriction on the free movement of goods. The goal of this judgment was to prevent protectionism of national governments. However, if consumers are unable to distinguish different national quality standards of a product, this judgment could result in Europe settling at an equilibrium with inefficiently low product standards (Sinn 1997). Thus, considering that regulatory competition is not efficient, Sinn (2003) contends that more centralized actions in the EU should be considered. In this sense, a central supervisory authority that supervises product quality from a consumer protection perspective would be helpful – as in the case of the US Food and Drug Administration.

Summary and Outlook

Regulatory competition in the spirit of the Tiebout (1965) model today is a widespread phenomenon on the regional, national, and global level. Lawmakers permanently attempt to direct individuals, companies, and capital to their home jurisdictions by changing their applicable law and infrastructure vis-à-vis those in other countries. While this process often improves the conditions for legal entities to conduct business and other operations, in certain situations it might also lead to a race to laxity. Regulatory harmonization might then be the policy tool of choice and is, for example, argued to foster financial stability in capital markets. Yet, the so-called Brexit vote, in which the citizens of Great Britain recently decided to leave the EU, can be interpreted as an attempt to flee European harmonization and become more flexible to engage in regulatory competition again. The UK prime minister, for example, already endorsed a move by the previous conservative government to reduce the corporate tax rate, not least to attract foreign companies. However, the introduction of regulatory uncertainty in other areas of the law could backfire, especially if legal entities prefer regulatory certainty to more benevolent legal rules. Thus, future research might investigate the trade-off between the benefits of harmonization and regulatory competition, how nation-states and supranational organizations should optimally position themselves in a multi-level setting such as the EU, and which welfare effects the various actors can expect.

With regard to regulatory competition in the form of unbundling of legal rules, the debate among US scholars largely ended in the 1990s, with some scholars proclaiming that the regulatory race is a “race to nowhere in particular” (Bratton 1994, p. 401). As such, regulatory competition at the US state level has frequently led to desirable results but has also been shown to have mixed effects for shareholders such as in the case of takeover legislation (Romano 1992). In Europe, the debate is not entirely solved yet.

Although we attempted to draw a comprehensive picture of the regulatory competition literature, many areas could not be covered because of

the limited scope of this chapter. Researchers have *inter alia* also investigated regulatory competition in the domain of marriage law, the legal process and arbitration procedures (O'Hara and Ribstein 2009), as well as competition law (Gabor 2013).

Regulatory Impact Analysis Meets Economic Analysis of Law: Differences and Commonalities

Wolfgang Weigel

Faculty of Business, Economics and Statistics,
Department of Economics, Joseph von
Sonnenfels Center for the Study of Public Law
and Economics, Vienna, Austria

Definition

Regulatory Impact Assessment is a tool for law-making, which makes use of economic criteria and techniques, such as Pareto-efficiency and cost-benefit analysis. It has been developed from the mid-seventies of the twentieth century and until now is in use worldwide, mainly pushed by OECD and the European Union. RIA reflects pragmatism.

The economic analysis of law, although having early roots in Europe at the age of enlightenment, has become a worldwide renown scientific approach and a vast field of interdisciplinary research at the intersection of economics and the law. It meets highest standards of sophisticated research and at the same time serves as methodology for policy recommendations.

Wolfgang Weigel has retired.

For decades the two fields developed without explicit reference to each other. So the question emerges, what they have in common and what are the differences. This is shown and complementary use is advocated.

What's Up?

In this entry it is shown what “Regulatory Impact Assessment” has in common with the economic approach to the law or “law and economics.” Intuitively, “regulation” and “laws” have a common scope. Moreover, they can be treated with the same tool: economics. But what makes them differ? For one it is the history of origins; this is remarkable inasmuch most of the time, there are no mutual references! Secondly it is in the purpose and thirdly in the range. While laws form the molecules of the judicial framework of every society, regulation is seen to form an essential part of economic policy making. However, in the influential view of the Organization for Economic Cooperation and Development (OECD) regulatory impact assessment – RIA for short – takes a much wider stance than the law inasmuch it is a tool, which meanwhile even by scholars of the doctrine of law-making (*Gesetzgebungslehre*) is acknowledged as the most comprehensive among the tools for the accomplishment of their task (Schäffer 2007)! But how does this fit into the observation that with respect to economics RIA seems essentially to rest on cost-benefit-analysis and little else, while the economic analysis of law makes use of the full range of microeconomic theory. Still there is a bracket around these which is welfare economics and a more comprehensive approach named new institutional economics, to be outlined later.

In order to elaborate on the commonalities and differences of RIA and Law and Economics, in the entry I proceed as follows: section “[The Notion of “Regulation” and the Focus of “Regulatory Impact Assessment”](#)” deals with the notions of “regulation” as well as “regulatory impact assessment” (RIA for short), a brief history of RIA and distinct properties. It follows a refresher of the approach of the economic analysis

of law (EAL) in section “[A Bird’s Eye View of the Economic Analysis of Law](#),” the core- chapter on the comparison (section “[The Overlap](#)”), followed by a brief outlook (section “[Outlook](#)”).

The Notion of “Regulation” and the Focus of “Regulatory Impact Assessment”

Regulation

It is important to note that the term “regulation” here is not meant in the narrow sense of imposing government constraints on private undertakings alone!

In fact, regulation is understood as a particular kind of incentive mechanism, namely, a set of incentives established either by the legislature, government, or public administration that mandates or prohibits actions of citizens and enterprises. Regulations are supported by the explicit threat of punishment for noncompliance (ideas on which scholars of EAL definitely will perfectly agree).

Finally, regulation here includes the full range of legal instruments and decisions – constitutions, parliamentary laws, subordinate legislation, decrees, orders, norms, licenses, plans, codes, and often even “grey” regulations such as guidance and instructions. Note that this view of regulation contrasts to the usual and somewhat narrower understanding of regulation as, for example, in Ogus (2004).

And when President Barack Obama made Cass Sunstein of Harvard head of the Office of Information and Regulatory Affairs (OIRA), even “nudging” became part of the regulatory arsenal. Here, nudging refers to means, by which people are gently induced to make appropriate decisions or act in a specific way. No explicit constraints are used and no particular enforcement mechanisms.

The instrumental use of regulation is closely tied to “market failures.” From existing manuals by OECD and from instructions provided through several US-presidents’ executive orders, the following list emerges:

- Monopolies and natural monopolies
- Information Inadequacies

- Continuity and availability of services
- Anticompetitive behavior and predatory pricing
- Moral hazard in the presence of public goods
- Unequal bargaining power
- Scarcity and rationing
- Distributional justice and social policy
- Rationalization and coordination
- Planning
- Myopic behavior

One important observation regarding the use of regulation must be stressed here: Public policies can be classified as “resource” – intensive and as “regulation” – intensive. To illustrate: A government may intend to cut carbon-dioxide-emissions by the reduction of exhaust-fume of cars. This can readily be pursued by an order, stating that car-owners are obliged to prove installation of the most advanced catalytic converter in the car by the end of the year. This would be at the cost of the owners and just leave enforcement costs with the government. However, we could imagine that government wants to make sure that the task is accomplished with minimum delay and allocate a certain amount out of the budget for the installation of the devices. This truly would be a resource-intensive undertaking. So with respect to public policy, spending and regulation are substitutes here!

However, since spending programs by the rule of law must rest on a law, the view put forward above requires some “metatheory of regulation,” which conveys the rationale for an initial framework of some order. As will be pointed out a little later, “new institutional economics” could serve as such metatheory.

Having investigated the notion of regulation, it is now time to turn to.

Regulatory Impact Assessment

A RIA is simply a way of gathering and organizing information about the expected impacts of a law or regulation and its major feasible alternatives. (Morrall 1994, p. 3, see also this Encyclopedia, Lanneau, R., “Regulatory Impact Analysis”)

“The purpose of RIA is to improve the quality of government interventions. It operates on familiar

principles and seeks first to ensure that the impacts both intended and unintended of proposed legislation and regulations are assessed in advance, and form an input into decision-making. RIA begins by answering the questions: Will the proposed intervention actually cause welfare to increase? What are the economic effects, i.e., how do the benefits stack up against the costs?" "Next, RIA highlights the strictly redistributive impact of proposed government intervention and establishes precisely who wins, who pays and how much" (Quotations from manuals on RIA by OECD 1997a).

Basically, a RIA has two underpinnings, one being an almost exhaustive checklist for regulatory undertakings and the second a rigorous cost-benefit analysis. The gist of the checklist is the following (Council of the OECD 1995):

1. Is the problem correctly defined?
2. Is government action justified?
3. Is regulation the best form of government action?
4. Is there a legal basis for regulation?
5. What is the appropriate level (or levels) of government for this action?
6. Do the benefits of regulation justify the costs?
7. Is the distribution of effects across society transparent?
8. Is the regulation clear, consistent, comprehensible, and accessible to users?
9. Have all interested parties had the opportunity to present their views?
10. How will compliance be achieved?

This list obviously requires typical considerations rooted in economic analysis, such as looking for alternatives and their consideration, as well as cost benefit analysis (see this Encyclopedia, Torriti, J., "► [Cost-Benefit Analysis](#)"). Moreover, it stresses procedural rules (cf. point 9) as well as typical issues of compliance and enforcement, respectively (cf. point 10) (which are, almost needless to say, considerations most familiar to the scholar of the economic analysis of law).

Ultimately, each of these questions requires treatment of the following steps: An analysis of the status quo as well as the need of intervention, an analysis of alternative ways to come to grips with a problem, including consultations and the collection of information. From this the

most preferred action should emerge, depicted in adequate measures, which then allow drafting (Renda 2010).

The generality of the procedures conveys a hint as to why in the doctrine of law-making RIA has such a prominent stance.

From First Oil-Crisis to Smart Regulation: A Very Brief Look on the History

After the oil-price-shock of 1974, the Ford-administration initiated measures to stabilize the economy with primary concern about inflation and employment. To this end, all regulations had to be checked for their effectiveness and subsequently reconciled with the "office of management and budget." So in the very beginning it was a device to check macropolicies. However, it were the frictions in the implementation of the policies, which were the primary focus of said checks! The respective attempts appear to have been quite promising. Consequently the first executive order regarding the systematic use of RIA was enacted by President Reagan 1981, (Order 12291). There one could read: "Regulatory action should not be undertaken unless the potential benefits to society for the regulation outweigh the potential costs to society ... Regulatory objectives shall be chosen to maximize the net benefits to society."

While RIA enjoyed changing popularity in subsequent years, it received stimulation from a study by Hopkins (1996), who shows that the aggregate compliance cost from federal regulation borne by the private sector and territorial authorities amounted to US \$ 668 billion or approximately 10% of GDP in 1995. This was, when the struggle against frictions in the economy due to flaws in regulation started, aptly illustrated by the upswing of the "office of information and regulatory affairs," founded by President Clinton through executive order 12866, which quickly reached 40 permanent staff.

Whereas several countries outside the USA fairly early adopted RIA, the boost came from an initiative of (OECD 1997b) regarding "transition economies," culminating in the program SIGMA (Support for Improvement in Governance and Management in Central and Eastern European

Countries) and PUMA (Public Management Service). Via OECD it entered the EU, where it first was adopted under the label “less and better regulation” which has muted to “smart regulation” meanwhile, being widely used, as can be seen from an ever increasing number of studies on <http://ria-studies.net/en> (cf Renda 2010).

Where Hope Lies There Is Also Disappointment

RIA for sure corresponds to the claim of a comprehensive approach. It meets several demands to a tool of law-making, the most prominent being lucidity and traceability, flexibility, and consistency. Moreover, it meets technical standards of lawmaking such as terminology and the allocation of competences, but also standards of implementation, such as practicality, feasibility, enforceability, but also acceptance.

The most prominent features are however those of economic efficiency as well as effectiveness, where the former is enhanced by cost-benefit analysis as the economic core of the tool. In a nutshell, the basic structure of every CBA is to secure that $B(x) - C(x) \geq 0$, where B are the (aggregated social) benefits (appropriately measured) of an act such as lowering/increasing the degree of regulation to some desired level x and C are the (social) costs. In the case of a continuous variation of x the criterion requires that $\partial B/\partial x = \partial C/\partial x$, constraints and contingencies notwithstanding.

The benefits B , accruing from some project (level of regulation) x , are captured by the (consumer) surplus brought about at prevailing (imputed) price of some regulations.

The basic structure of CBA is structurally equivalent to the Kaldor–Hicks test, which means that ostensibly there is a rigorous criterion for the selection of solutions to a regulatory agenda. However, one has to be cautious here for at least two reasons.

Leaving the tool itself unquestioned, the Kaldor–Hicks test itself has a serious weakness in its distributional ambiguity: To illustrate, assume that the benefits from some environmental measures go to a densely populated area, while the (opportunity) costs are borne by taxpayers. Then

the aggregated individual benefits may be equally distributed among the beneficiaries. But assume now that the beneficiary is a single entrepreneur owning the large parcel of land, which will increase in value to the level B . Such effect makes the beneficiary in a sense privileged, although the criterion for potential compensation still holds.

But there is a still harder objection: CBA carried out *lege artis* follows a couple of strict assumptions rooted in neoclassical microeconomics. And it is held that in many cases these could – or should – not be applied, which can easily be seen from the increasing number of deviations from neoclassical results brought about by “behavioral” and “experimental” economics, respectively (Camerer et al. 2011)

It is worth mentioning here that in the EU a “better regulation package” was released in May 2015, which partly took account of the methodological weaknesses just pointed out.

With respect to the relatedness to the “economic analysis of law,” the following features of RIA should be recalled:

RIA is definitely rooted in Paretian welfare economics (see the citation from President Reagan’s executive order, *supra*)

Closely related to the latter is “methodological individualism”

RIA takes a weak “consequentialist” view. This can be inferred from the OECD-checklist (*supra*), which implicitly at least asks for ethical or moral justifications. Moreover, the questions regarding distributive issues as well as the comprehension of affected groups underline this view inasmuch they point to certain underpinnings regarding standard perceptions of a society.

Before some commonalities and differences are pointed out, a view on the “economic analysis of law” (EAL) is due.

A Bird’s Eye View of the Economic Analysis of Law

Given the broad understanding of RIA in the view of OECD (which is shared by the EU), one may ask, if in law and economics the notion of a “law” might have a different meaning here than in the

concept of RIA. Well, upon inspection of some definitions of a law, one does not get a clear idea. Here are just two tasters:

“A rule of conduct or procedure established by custom, agreement, or authority” or “A statute, ordinance, or other rule enacted by a legislature.”

Both give rise to similar implications: it is not the “nature” of the legal rule which is at stake, but the way of formation through a distinct procedure.

This is, why the law eventually is contrasted to “norms” and “standards,” as, for instance, in a well known article by Michael Adams (2002). The latter are seen as outcomes of voluntary agreements (within an industry, say) or collective action of some kind, as in the exceptional book on “social institutions” by Schotter (1981).

This notwithstanding, the legislature might have some discretion in choosing the rule, which is established, provided it is backed by the superordinate legislature.

Unfortunately, the domain of the economic analysis of law appears to be slightly broader than that (in the meantime). Recall that sometimes – and especially with respect to international law – it is referred to “soft law” (Gersen and Posner 2008).

So summarizing “law” and “regulation” do overlap to a considerable extent with respect to the domain.

What about the scope of analysis?

In contrast, look at this: “Economic analysis of law seeks to answer two basic questions about legal rules. Namely, what are the effects of legal rules on the behavior of relevant actors? And are these effects of legal rules socially desirable?” (Kaplow and Shavell 2002, p. 1661), and one must add: how can they be improved so as to meet the measures of social efficiency?

Since the law guides the legislature, the executive branch, as well as the judiciary, the domain of the approach is all-encompassing.

In pursuing its purpose, the approach follows

- Paretian welfare economics
- In particular a methodological individualism
- Most of the time assuming rationally deciding people (“homo oeconomicus”)
- And a consequentialist view.

However, the quickly emerging psychology-prone contributions appear to lead to an erosion of both, the rationality-assumption and consequentialism, since the patterns guiding judgement as well as decision are more and more coming to the fore.

The Overlap

Before looking at the commonalities, one remarkable detail in the history of RIA is worth stressing: Looking at the publications dealing with RIA and as mentioned in the introduction most of the time, there is no reference whatsoever to the economic approach to law (and vice-versa!). To assure oneself, one might consult the OECD’s website on this issue, but this would be in vain! One thus gets the impression that the approach neglects the many valuable insights from an economic analysis of law regarding incentives of people in any social role, consumers, entrepreneurs, politicians, bureaucrats, judges, mothers, thieves, whatever, despite the fact that regulation is considered an “incentive mechanism” (supra, at section “[Regulation](#)”).

However, while after first inspection, the main tool of RIA is identical with the main tool of EAL, evidently there are considerable differences which come to mind immediately. The most important of these differences seems to be that in the course of a RIA typically no analysis is undertaken, of how a single representative individual would react to a norm; that is to say, how this person would calculate expected benefits and expected cost, so as to make the inherent incentives and likely transaction costs (broadly defined) of some regulation more visible. Instead, an aggregate measure is sought right away.

Now it is beyond the scope of this note to treat the steps of a RIA in detail. However, some of the requirements, as laid down in several guidelines as well as the Clinton Directive (Executive order 12866), deserve mention:

One such requirement is the “statement of need,” which is supposed to justify government

intervention (a list of reasons for regulation has been given above).

Moreover, the possibility of “over-regulation” due to preceding rent-seeking must be stressed here, which, in terms of economic analysis of law, can be seen as a treatment of malfunctions of a law, thus fitting into the list of purposes according to Kaplow and Shavell (*supra*).

But from time to time RIA appears to be even a kind of extension of the domain of the economic analysis of law (EAL). The importance and the relevance of EAL lies in the general and robust theoretical results, e.g., regarding incentives of all kinds (e.g., regarding liability rules vs. property rights or different kinds of punishment and so on). In contrast and taking a normative stance, the aforementioned directives point out that different standards of safety and quality of commodities are legitimate according to specific demands; even the legitimacy of barriers to entry for distinct professions is stressed, one example being pilots.

Consequently, what scholars of EAL would discuss under the label of “alienability” of property rights is addressed. Property rights here are understood as “sanctioned behavioural relations among men that arise from the existence of goods and pertain to their use” (Furubotn and Pejovich 1974, p. 3).

From such considerations to the emphasis to analyze alternative structures of property rights (institutions), it is just a fairly small step. To illustrate: the Clinton directive requires to take into account lawsuits and taxation as alternatives to regulatory measures.

One advantage of EAL over RIA definitely is the explicit consideration of transaction costs (on the notion: this Encyclopedia, Vereeck, L. et al., Transaction Costs). Recall that these costs are seen as the obstacles to the internalization of externalities. Therefore, they cannot be grasped as indirect cost or stemming cost within the typical classification of a cost-benefit analysis. They are, on the contrary, instrumental to such costs: To illustrate: Where clarification of property rights will not work, transaction costs suggest clear guidelines, which then allow for bargaining in the shadow of the law.

Moreover, RIA seems to abstract entirely from the role of courts, an issue, on which EAL has a lot to say. Bearing in mind that RIA is embedded in the broader concept of regulatory reform, which in turn is summarized by the guidelines stated in section “[Regulatory Impact Assessment](#)” above. Upon inspection, one learns that in some respect, these guidelines advocate a partial approach: while it is recommended to ask, whether regulation was the appropriate form of government intervention, it is not explicitly recommended to consider alternative institutional settings (as first suggested by Ronald Coase in his seminal 1960-article).

Now it is definitely true that EAL might be less conclusive on the aggregate level than RIA: This might follow from a typical way of reasoning within the law and economics framework: Frequently, the generalized consequences for resource allocation emerging from the way in which a judge handled a particular case are at stake. The famous “Learned Hand” formula may serve as an illustrative example (forming part of the set of robust results pointed out above). Here, the problem at hand – the liability of the “cheapest cost avoider” – is worked off by induction, that is to say by the generalization of considerations in the course of handling the case *United States v. Carroll Towing Co* (159 F.2d 169 [2d Cir. 1947], excellent description of the case in Cooter and Ulen 1988, p. 360 *passim*). RIA, with its flavor of pragmatism, takes a different approach. However, given the broad definition and the subtle claim of the more recent development of RIA (see section “[Regulatory Impact Assessment](#),” *supra*), one wonders why there is so little mentioning of, e.g., incentives and the presence of obstacles to action (i.e., transaction costs).

Maybe that the evasion of such subtleties is the price one has to pay for the explicit intention of OECD to provide a tool for a standardized treatment of a very broad range of issues.

Such observations open out into the question, whether RIA and EAL are not so much two fields with a common overlap, but rather closely related branches of a common approach, which might be labeled “new institutional economics” (see this Encyclopedia, Randa, R., “► [Institutional](#)

Economics”). As an underpinning of the institutionalist view of the economy, one may recall George Stigler here. In his Presidential Address at the occasion of the 1964(!) meeting of the American Economic Association he stated: The competence of economists “...consists in understanding how an economic system works under alternative institutional frameworks,” and one is tempted to say: consequently: “The basic role of the scientist in public policy, therefore, is that of establishing the costs and benefits of alternative institutional arrangements.”

Although it is not an easy task to give a definition of such a broad term as “institution,” it ought to be outlined at least. An Institution is a system of formal and/or informal rules, which by consent guides human actions in a particular way and contains remedies for enforcement. Furubotn and Richter (1997) offer a comprehensive view on this approach. So very briefly, what is (new) institutionalism about? Economics traditionally deals with decisions over scarce resources. Thus, the constraints caused by scarcity are at the core of economic research. But there is a second set of constraints, which deserves attention: these are norms of all kinds, which govern human behavior in society. Such norms can take the form of laws, but – as has already be stated – they also comprise informal rules, customs, and traditions. They can be the result of explicit collective decision making, but they may also emerge tacitly. They are subject to change or they may be violated. The by now well established New Institutional Economics concentrates on the analysis of the emergence and change of such norms, their effect on human conduct as well as conditions for and consequences of violation. The work on both RIA and EAL may be comprised as subsets of that broader approach, which serves as the “meta-theory” here for reasoning about the emergence of norms in general.

Outlook

At first sight RIA has a strong flavor of pragmatism, much stronger than the more academically prone Economic Analysis of Law: the image

of EAL meanwhile might be to be primarily an academic approach, a playground for quibblers, whereas RIA, despite the efforts to broaden its scope and to deepen the theoretical underpinnings, has conquered the marketplace for ideas as a tool designed to be applied for the practitioner. But EAL has not been developed just as a toy for contemplation of theoretical curiosity. The contrary is true: In the USA at least, it grew out of a down-to-earth request for reform (compulsory accident insurance for car-owners). And its advocates in Europe and other parts of the world always had the aspiration of reforming or at least complementing the orthodox approach to the law by a strictly analytical approach. In some sense, RIA does much the same as EAL does in some distinct areas of application. But the approach of RIA is pushed by the EU, OECD, and various member-states and has been strongly advocated and applied earlier in the USA, whereas EAL does not enjoy such almost continuous promotion; rather it is there to be discovered.

In this contribution the commonalities and differences in the two approaches have been investigated and the conclusion is that RIA and EAL not only do meet, meaning that they have much in common. Definitely they cannot merge. Rather they can be grasped as parts of a broader approach: that of new institutional economics. There they should meet, for the benefit of our society.

Regulatory Impact Assessment

Régis Lanneau

Law School, CRDP, Université de Paris Nanterre, Nanterre, France

Abstract

If regulation is often perceived as a tool to increase welfare, it is not infrequent that it leads to unintended consequences; examples are numerous. The purpose of regulatory impact assessment is precisely to help political decision-makers to identify whether and how to regulate while also defining a conception of the public interest that could then be debated. This entry will explain the logic and the development of RIA.

Introduction

If regulation is often perceived as a tool to increase welfare, it is not infrequent that it leads to unintended consequences; examples are numerous. After all, regulating in an evolving world of inherent complexity (and interdependence between economies) and uncertainty is not an easy task; it is the reason why it is bound to be a never-ending process. Nevertheless, it is not because perfect regulations are not from this world that it is not possible to develop tools to reduce the amount of inefficient regulations, especially when these regulations could be expected to impact many domains of a national or a regional economy. Regulatory impact assessments (RIA) are precisely trying to contribute to this aim by requiring regulators to assess the probable consequences of their regulation for the economy using models,

data, and evidence. These RIA are also supposed to help political decision-makers to identify whether and how to regulate while also defining a conception of the public interest that could then be debated. It is not then surprising that the practice of RIA is highly recommended by the OECD (1997) and part of its indicators to measure regulatory performance (see Radaelli 2004, for an explanation of the diffusion of RIA).

From the point of view of law and economics, RIA is both the recognition of its practical relevance and its inherent limitation for regulators and policy makers. Moreover, it helps to understand the real value of law and economics.

The Economic Logic Behind Regulatory Impact Assessment

In traditional law and economics, regulations are required in two situations: when the regulation can reduce transaction costs (defining the basic entitlements and the way to exchange them) or when it is supposed to reduce market failures (externalities, asymmetrical information or market power) (see Baldwin et al. (2010)). Nevertheless, as public choice emphasized, unproductive profit seeking by special interest groups to secure favorable regulation is definitional of the regulatory process (Tullock 1967), so there are no reasons why rational policy makers should implement only public interest regulation (Stigler 1971; Posner 1974; Peltzman 1976) without external constraints (public opinion's pressure or procedural requirement). Hence, regulations could merely be designed to redistribute wealth, and, when it does, these regulations should be considered as highly suspicious. This does not mean that, from an economic point of view, it is not possible to engage in policy choices but that these choices should be made sufficiently clear in their consequences to avoid the lurk of blindfold populism and moralism, an unavoidable risk in any democracy.

The mere need of RIA for enacting "better and smarter" regulations cannot be explained if it is possible to consider that regulations are only driven by the public interest and efficiency

requirement. RIA is thus a tool to overcome some regulatory failures. It is not a tool to make sure that regulations are efficient but a tool to ensure that they are not blatantly inefficient because it is forcing policy makers and regulators to justify their policy not only through a political rhetoric but through an explanation of the trade-offs they are engaging in and the requirement to quantify and identify the public interest based on the best data available (of course the quality of the data will be crucial, Torriti 2011).

Of course, since RIA are costly (administrative cost and delay are necessarily creating such costs), their necessity and precision are dependent on the regulation at stake (Rose-Ackerman 2016). It is only because RIA are supposed to lead to some social benefits (avoidance of bad measures, welfare gain from enacting what appeared to be efficient) that its costs could be justified. It is then to be anticipated that RIA requirement should be higher when the regulation at stake, either by its breadth or magnitude, is significantly impacting the economy. The fact that this requirement appeared in the field of environment and health should not then be a surprise (see also Arrow et al. 1996; Livermore and Revesz 2013).

Regulatory Impact Assessment as a Process

A. Three stages of RIA could be distinguished: description, identification, and quantification (see also European Commission 2009; for an overview of the methods and domains, see Dunlop and Radaelli 2016).

At first a RIA should explain what is the problem (identification and definition) the regulation is supposed to curb and why an action is required. At this stage, this is the need for an intervention that should be assessed. Using economic theory, this need should be either a market failure or a means to reduce transaction costs.

The second stage is inquiring into the regulatory options. Indeed, a same problem could be addressed using a variety of regulatory tools

from command and control to economic incentives to mandatory disclosure or nudges. It is not only the “specie” of regulatory option that should be considered but also the variety within the “specie.”

The third stage is dedicated to the quantification of the direct and indirect benefits and costs of each option (including the administrative and information regulatory burden; see also, more generally, Marneffe and Vereeck 2011; Hahn and Tetlock 2007). Of course, the benefits and costs can only be assessed through a set of hypotheses or choices regarding, more especially, the valuation methodology and baseline scenario. These hypotheses are crucial to assess the subjective value of the RIA for policy making (see, e.g., Ogus 1998; Rose-Ackerman 2011a; Hahn and Litan 2005). It will then be possible to compare options and eliminate obviously relatively inefficient options.

Being transparent about all these stages could contribute to a better accountability of regulators (since trade-offs are made clear) and to an increased consistency in regulations (since the need of a new regulation is explained). Moreover, with experience in RIA, better data and analytical methods should be expected to emerge. RIA is, from this point of view, a learning by doing a process.

B. RIA is not only a document (or a set of documents) providing information regarding the expected consequences of a regulation (an end result); it should be conceptualized much more as a process (Adler and Posner 2006). Indeed, as an “end result,” it could be considered as a mere new rhetoric to justify regulatory choices; the hypotheses would then be chosen *ex post* to justify the desired regulation which will then be submitted to some formal or informal political debate – it is quite often this instrumental use of RIA that is criticized (Renda 2006). Conceptualized as a process, RIA exhibits two interesting features. First, it makes clear that RIA is a way to inquire into a regulatory problem: neither the problem nor its options are facts; they are identified and assessed differently depending on the state of knowledge. RIA, once made, is then not an end result but a “first draft” that will evolve

with the comments and criticism of stakeholders. Second, RIA is not a stage after drafting a regulation; it should be developed in parallel of it to reduce the likelihood of an instrumental use. This also requires a complete transparency of the process.

The Rise of Regulatory Impact Assessment

The rise of RIA began in 1974, in the USA. President Ford’s executive order 11821 established procedures for preparing inflation impact statements that were designed to illuminate the economic impact of regulatory proposals, specifically their effects on productivity and competition. Nevertheless, it is at the beginning of the 1980s that it became the mainstream in the USA. Indeed, President Reagan’s executive order 12291 of 1981 states that “Regulatory action shall not be undertaken unless the potential benefits to society from the regulation outweigh the potential costs to society.” Another 20 years was required for RIA to spread among OECD countries. During the 1990s and before 1997 (year of the first OECD publication on the subject even if RIA were recommended by the council of OECD in 1995), less than 10 OECD countries had comprehensive RIA program, by the end of 2000, 14, and since 2008, more than 30. Nowadays, almost all OECD countries have such programs despite differences (among which the definition of the type of regulation and intervention submitted to RIA). For example, in France, only primary legislation prepared by the government is subjected to RIA to the exclusion of all secondary legislation.

There are very few studies analyzing the potential of RIA for developing countries (Kirkpatrick and Parker 2003); Korea and Mexico are often mentioned as good examples of RIA design. However, in most developing countries, when RIA are present, they are not systematically used, and the methodology developed remains largely incomplete (Kirkpatrick et al. 2003). Rodrigo (2005) highlights the political requirements allowing RIA to prosper.

Conclusion

Even if RIA are often targeted as promoting “conservative” regulations and “deregulation,” it is hard to deny the necessity of assessing the consequences of regulations. Once again, the purpose is not to make sure that only good regulations will be enacted or to avoid all negative unexpected consequences but to reduce the likelihood of bad regulations by clarifying available regulatory options. RIA should remain a tool to inform policy makers and regulators (see also Jasanoff 1990; Rose-Ackerman 2011b); it can be used adequately if and only if its limits are well identified (regarding model hypotheses and data quality and aggregation).

Rent Seeking

Christopher J. Coyne and Garrett Wood
Department of Economics, George Mason
University, Fairfax, VA, USA

Definition

This chapter explores the concept of rent seeking. When resources earn returns in excess of those they could earn in their next best opportunity, economists call those returns “rents.” In the market, the seeking of rents is known as profit seeking; in politics it is known as “rent seeking.” Profit seeking generates social value through the competitive market process. Rent seeking results in social losses as finite resources are used to pursue transfers of wealth rather than in the production of new wealth. This entry explores the distinction between rent seeking and profit seeking and discusses the implications.

Introduction

Economic rent accrues to owners when their resources earn returns over and above those resources’ opportunity cost. Rents can exist in private markets or in political settings. In private markets, rent seeking is referred to as “profit seeking” to denote that it generates a social surplus that is beneficial to society. In contrast, in political settings rent seeking generates social costs that are harmful to society. The next section explores the distinction between profit seeking and rent seeking in greater detail. We then discuss the problems with rent seeking for social welfare. The conclusion discusses the implications.

Profit Seeking Versus Rent Seeking

Since rents are nothing more than resources earning returns above their opportunity cost, it is important to make the distinction between circumstances in which pursuing rents is productive

versus circumstances in which it is unproductive. Let us begin with rent seeking in the context of competitive markets.

In markets, entrepreneurs seek new opportunities to earn profits by reallocating scarce resources to new and better uses. This process is guided by market prices and subjected to the profit and loss test, which provides feedback as to whether the entrepreneur has been successful in increasing social value (Kirzner 1973, 1992, 1997; Thomsen 1992). A first-moving innovator, for example, who brings a profitable product to market, will earn a rent. However, these are “quasi-rents,” a term intended to indicate that, in competitive markets, profits are temporary. The reason they are temporary is that in competitive markets, these quasi-rents will attract other entrepreneurs who will enter the market and erode the profit earned by the first mover. This process is socially beneficial because it leads to the efficient allocation of scarce resources. For this reason, rent seeking in the context of the competitive market is referred to as “profit seeking.”

In political settings, rent seeking has dramatically different welfare implications. The political production of rents is artificial in nature and depends on practices, such as the granting of monopoly rights which raise barriers to entry, which destroy social wealth. Government-granted monopoly rights transfer a portion of consumer surplus to the monopoly producer. Part of the cost are foregone trades which otherwise would have taken place, resulting in a deadweight loss. The transfer itself, however, creates a pool of resources to be won and attracts fierce competition to secure the right to earn those profits (Tullock 1967). The difference in this scenario from that of the market situation, however, is that the competition in politics is over securing permanent privileges that prevent the erosion of rents (Buchanan 1980). While profits in markets represent quasi-rents, the rents earned through political competition endure precisely because the competition is over government-created protections from market forces.

Posner (1975) posits a rent-seeking game where a monopoly right worth \$100,000 is bid for by ten risk-neutral rent seekers who cannot

recover their bids should they lose the game. Each bidder offers \$10,000 resulting in the complete dissipation of rents. The \$100,000 in bids spent in pursuit of the \$100,000 in rents constitutes a social loss to the extent that the lobbying process is spent on activities that do not increase total social wealth by creating new value. Instead, these expenditures are made to secure the transfer of existing wealth.

Tullock (1967) compared the losses from rent seeking to the losses from counterbalancing investments in tools for thievery and safeguards against theft. Resources spent on the tools of thievery and preventative measures against thieves do not increase the size of the prize being sought or protected. Neither do resources spent by competing lobbyists to secure a government privilege, resulting in social waste.

Further exacerbating these social losses is that investments in rent seeking are specific. Resources spent by one individual developing influence over the politicians creating rents are mostly lost because that influence is difficult or impossible to transfer to another individual if the bid for rents fails. The social cost of rent-seeking activities is measured by the opportunity cost of the resources used. Entrepreneurs who direct their efforts to curry favor with politicians for narrow privileges cannot simultaneously exert that effort to provide a superior good or service for private consumers.

Certain scenarios can reduce the amount of rent seeking below the level of complete dissipation modeled by Posner. Baysinger and Tollison (1980) introduce consumers and consumer groups as interest groups capable of organizing to resist the creation of rents. The efforts of these groups reduce the expected payout of rent-seeking activities and thus results in lower bids and fewer resources wasted. In their model, consumers will tend to organize where the expected success of their counter-lobbying efforts is higher than the combined expected costs of organization and rent creation. Tullock (2001) models a rent-seeking game in which players are in marginal balance, each bidding \$25 for a prize of artificial rents worth \$100. The result is inframarginal gains from winning the game. This result depends on

players knowing how to find the optimal bidding strategy and knowing that the other player will also find it, an assumption that becomes more reasonable in instances of repeated play between professional lobbyists.

The incentives of the political agent creating rents must also be taken into account. Peltzman (1976) introduces political actors who face a trade-off between the rents they create for interest groups and the votes of their constituent consumers. The politician attempts to weigh the benefits gained from lobbying by rent seekers against lost votes from those constituents who incur a sufficient cost and alter their vote accordingly. Politicians are therefore incentivized, though perhaps weakly depending on the specific context, to limit the amount of rents they create in order to preserve enough votes to get reelected.

The Problem of Rent Seeking

Rent seeking encourages the use of scarce resources in competition over pools of wealth transferred from one party to another instead of in a competitive process that produces new wealth. This is harmful to the well-being of the members of a society because scarce resources are used to secure existing wealth as compared to creating new value. While beneficial to the individuals who win the rent-seeking competition, the cumulative effect of rent seeking is the “decline of nations” as members of society become increasingly focused on securing transfers of existing wealth (Olson 1982).

The extent of the problem posed by the creation of rents was underestimated for many years (Tollison 1982). Harberger (1954) demonstrated empirically that the deadweight loss to society from monopolization in US manufacturing around 1929 was low compared to GNP, less than 1% in fact. Harberger’s calculations, however, did not account for the costs of rent seeking. Krueger (1974) found that rent-seeking activity in the Indian public sector accounted for 7.3% of GNP in 1964, while rent-seeking activity in Turkish import licensing accounted for 15% of GNP in 1968. Rama (1993) found that

rent-seeking activities in Uruguay led to temporary sectoral growth, but an overall decline in economic growth. Del Rosal (2011) offers a survey of empirical estimates of rent-seeking costs as a percentage of GNP and GDP, the amount of resources misallocated to unproductive professions, and other indicators. These estimates of the costs of rent seeking have to be added to the costs captured in the Harberger triangle to form more accurate estimates of the overall costs of monopoly.

Given that costs to society of rent seeking are often significant, it remains to be explained why the legislation that creates rents is so rarely repealed. Tollison (1982) highlights key features of the rent-seeking game to explain this phenomenon. In a world of zero transaction and information costs, no rent seeking would occur because the groups who incurred the dispersed costs of rent seeking would easily organize to protect themselves. In a world with positive transaction and information costs, however, some groups will find it easier to organize for lobbying activity. The groups that find it feasible to organize will seek transfers of wealth at the expense of groups who cannot easily organize to resist their efforts. Groups organized for lobbying often involve members of industry or labor, but rarely do they form around consumers in general due to the costs of organization. The concentrated transfers to be won from successful lobbying efforts, combined with the high cost of organizing the numerous, dispersed consumers who shoulder the burden of rent seeking, prevent society from realizing the potential gains of repealing rent-creating legislation.

Conclusion

Baumol (1990) argued that while policy decisions are limited in altering society's overall supply of entrepreneurs, they can heavily influence the allocation of entrepreneurial efforts across different types of activities. In societies where large profits can be made through competitive markets, entrepreneurs will allocate their resources to engaging in productive, value-added activities. In societies

where rents can be earned through political means, in contrast, entrepreneurs will invest in unproductive, rent-seeking activities. The overall balance between productive and unproductive entrepreneurial activities is a function of the rules of the game which influence the payoffs associated with each type of activity. This logic offers crucial insight into the process underlying the economic rise and decline of societies throughout time and across geographic space.

Retributivism

Mark D. White
Department of Philosophy, College of Staten
Island/CUNY, Staten Island, NY, USA

Definition

A theory of punishment that maintains that wrongdoers deserve to be punished, in proportion to their crimes, as a matter of justice or right.

Retributivism is a theory or philosophy of criminal punishment that maintains that wrongdoers deserve punishment as a matter of justice or

right. It is often contrasted with deterrence, which justifies punishment on the basis on the future harms it prevents. (On theories of punishment, see the papers in Acton (1969), Duff and Garland (1994), and Simmons et al. (1995); for concise syntheses, see Tunick (1992) and Brooks (2012).)

Drawing on the terminology of moral philosophy, retributivism is often characterized as *deontological* in nature, being based on qualitative concepts of justice and the right, while deterrence is *consequentialist*, focused on minimizing the negative outcomes from crime. This is, admittedly, an overgeneralization: for instance, Moore (1993), Cahill (2011), and Berman (2013) have suggested that retributivism can be regarded as a consequentialist or instrumentalist theory in which punishment or justice are goods to be maximized (see Dolinko (1997) for a counterargument). Nonetheless, it remains that retributivism is linked to justice rather than welfare or utility, and this leads to more specific and useful ways to distinguish it from alternative theories of punishment.

Before we can fully appreciate retributivism, we must briefly discuss deterrence. The formal basis for deterrence can be traced to classical utilitarianism, particularly the policy recommendations of Jeremy Bentham (1781) and the criminology of Cesare Beccaria (1764). As punishment by its nature is harmful, it is justified only insofar as it prevents greater harm: “All punishment in itself is evil. Upon the principle of utility, if it ought at all to be admitted, it ought only to be admitted in as far as it promises to exclude some greater evil” (Bentham 1781, p. 170). One way punishment “excludes some greater evil” is through deterring future crime by incapacitating the guilty and creating an incentive for others to abstain from criminal activity, both of which lessen the incidence of crime going forward.

Deterrence is not focused on lessening crime itself but rather on minimizing the overall costs of crime, including not only the harms done by criminals but also the costs of punishment, prosecution, and apprehension. This inclusive definition of the costs of crime implies that some crimes will be unworthy of punishment because it is “*groundless*”: where there is no mischief for it to prevent. . .

inefficacious: where it cannot act so as to prevent the mischief. . . *unprofitable*, or too *expensive*: where the mischief it would produce would be greater than what it prevented. . . [or] *needless*: where the mischief may be prevented, or cease of itself, without it: that is, at a cheaper rate” (Bentham 1781, p. 171). It is no surprise that this general framework of deterrence was adopted by Becker (1968) and other economists as they began to study crime and developed theories of efficient punishment that refined and expanded on the early insights of Bentham and Beccaria.

Retributivism is not concerned with the effects of punishment on future behavior or costs but instead solely addresses the crime for which the perpetrator is to be punished. For this reason, retributivism is often referred to as “backward-looking,” focusing on the crime which was committed in the past, while deterrence is characterized as “forward-looking,” taking the past crime as given and exacting a punishment designed to minimize the future costs of crime. While deterrence sees no inherent value in punishment itself, but instead sees it as a tool to maximize utility or minimize harm, retributivism maintains that the state has a moral, political, or legal duty to punish wrongdoers.

While embedded in discussions of justice going back to Plato and Aristotle, the modern roots of retributivism are usually traced back to Immanuel Kant, for whom retributivism stemmed from his belief in the respect owed to persons due to their inherent dignity as autonomous beings. While his position on punishment is more complex than often acknowledged (as pointed out by Murphy 1987), several statements he made exemplify the basic tenets of retributivism. For instance, Kant held that punishment must be imposed only in response to the crime committed and “can never be inflicted merely as means to promote some other good for the criminal himself or for civil society. It must always be inflicted upon him only because he has committed a crime. For a human being can never be treated merely as a means to the purposes of another” (1797, p. 331). Kant addressed the danger of punishing the innocent and the other goals of

punishment when he wrote a person “must previously have been found *punishable* before any thought can be given to drawing from his punishment something of use for himself or his fellow citizens” (1797, p. 331). Along with Hegel (1821), Morris (1968), and Murphy (1973), Kant emphasized that retributivism is grounded in respect for the individual, giving the guilty what they are owed by virtue of what they did, as a matter of impersonal justice rather than the base emotions of revenge or vengeance (a distinction explored by Nozick (1981, pp. 366–368)).

Retributivism can be classified as either negative or positive. *Negative retributivism* places limits on the subject and severity of punishment: the innocent should never be punished, and the guilty should not be punished more than is proportionate to their crimes. *Positive retributivism* goes further, endorsing the upper limits on punishment imposed by negative retribution while also maintaining that the guilty must be punished and not less than is proportionate to their crimes (thereby imposing a duty of overall proportionality). (This distinction is usually attributed to Mackie (1985) and has since become standard in the literature on punishment.)

Negative retributivism is often seen as a side constraint on the pursuit of deterrence that prevents it from considering the punishment of innocents or imposing disproportionately severe punishments on the guilty. Deterrence constrained by negative retributivism is a common *hybrid theory* of punishment as suggested most famously by Hart (1968); some, such as Byrd (1989), argue that this was Kant’s complete view as well. While the intentional punishment of the innocent may be more of a theoretical possibility than a practical threat in most modern democracies, the practice of disproportionately severe punishments is a logical implication of efficient deterrence. For instance, Becker (1968) showed that, in many cases, enforcement costs can be lowered while achieving the same level of deterrence if the probability of punishment is lowered – reducing enforcement costs – while the severity of punishment is raised, most likely above a level proportionate to the crime. (One example is littering, which in the

United States carries an extremely low chance of apprehension and posted fines much higher than any measure of the resulting harm.) While this may be efficient from a cost-minimization point of view, the negative retributivist would object that it subjects the guilty person to a greater punishment than he or she deserves in light of the crime committed.

Positive retributivism adds the imperative of punishing the guilty and ensuring that the punishment not be disproportionately mild; as Kant wrote, “woe to him who crawls through the windings of eudaemonism in order to discover something that releases the criminal from punishment or even reduces its amount by the advantage it promises” (1797, p. 331). Since negative retributivism does not mandate punishment at all, some doubt whether it counts as retributivism (Cottingham 1979). But positive retributivism is “complete,” mandating that all wrongdoers be punished and in proportion to their crimes, with the punishment neither too harsh or too light in comparison to the crime.

However, the stricter nature of positive retributivism presents a number of problems both theoretical and practical. For one, while it is easy to argue that the innocent must not be punished, it is more difficult to argue why the guilty *must* be punished (without recourse to preventing future harm). Perhaps the simplest justification – if we can even call it that – is to invoke the ancient code of the *lex talionis*, “an eye for an eye and a tooth for a tooth.” Kant cites this approvingly when he asks “what kind and what amount of punishment is it that public justice makes its principle and measure? None other than the principle of equality... Accordingly, whatever undeserved evil you inflict upon another within the people, that you inflict upon yourself. ... But only the *law of retribution (ius talionis)*. ... can specify definitely the quality and the quantity of punishment” (1797, p. 332). The *lex talionis* certainly prescribes a strict proportionality which would be impossible in most cases, and it is seen by most retributivists as simplistic, harsh, and inhumane; some doubt its relevance to retributivism at all (Davis 1986).

Most modern retributivists justify due punishment on other grounds. Intrinsic retributivists maintain that punishment of the guilty is an intrinsic good that does not derive its value from any more basic precept. (See Davis (1972) for one example, arguing against Honderich (1984), who coined the term and criticized the concept.) But others find a justification for retributivist punishment in a broader political theory, often based on a version of reciprocity that maintains that the guilty “owe a debt” to society or their fellow citizens and punishment restores this balance (famous from Plato’s *Crito* (360 BCE); for surveys of such theories, see Tunick (1992, ch. 3), and Duff (2001, ch. 1)). For example, many retributivists, such as Morris (1968), argue that while innocent citizens bear the costs of compliance with the law, the guilty “free ride” on these efforts, gaining unfair advantage that must be repaid to restore balance (Kant was sympathetic to this view as well, according to Murphy 1972). Similarly, some retributivists maintain that the purpose of punishment is, in the words of Hegel (1821, p. 69), “to annul the crime, which otherwise would have been held valid, and to restore the right.”

Finally, there are justifications for positive retributivism that are not based on reciprocity, such as denunciation or expression of condemnation (Feinberg 1965; von Hirsch 1985; Markel 2011) and moral education and communication (Hampton 1984; Duff 2001). Note that these justifications are goal oriented in nature, focused on an end result of punishment, albeit one that is more specific than deterrence or harm reduction and also tied closely to the crime committed. Nozick (1981, p. 371) calls such theories of punishment *teleological retributivism* because they focus on an end other than the suffering of the guilty; Berman (2013) argues that most modern retributivist theories are teleological or instrumental in nature.

Another problem facing positive retributivism (and even negative retributivism to a degree) is how to determine a type and degree of punishment that is proportionate to – or “fits” – a given crime. The *lex talionis* demands literal proportionality, the spirit of which survives today in jurisdictions

which prescribe the death penalty for murderers despite questionable deterrent effect (Ehrlich and Liu 2006), but is impractical or unthinkable in cases like battery, rape, or attempted murder. Even Kant, who supported the *lex talionis*, appreciated its limitations, asking “but what is to be done in the case of crimes that cannot be punished by a return for them because this would be either impossible or itself a punishable crime against *humanity* as such?” and recommending that “what is done to [the wrongdoer] in accordance with penal law is what he has perpetrated on others, if not in terms of its letter at least in terms of its spirit” (1797, p. 363).

While equivalence is not possible, it is widely agreed that, at the very least, more serious crimes should be punished more severely. But even this determination is not as easy as it may seem: while various degrees of one crime, such as murder or theft, can be ranked and punished appropriately, determining proportionate punishment for two different crimes is more difficult. Card (1975), von Hirsch (1976), and Davis (1983) are seminal works in this area, but some (such as Wertheimer 1975) remain skeptical that a consistent, proportional system of punishment is possible at all. More fundamentally, retributivists disagree on what determines the severity of a crime: whether the harm done or intended, the degree of wrongdoing, or the culpability of the criminal. (See Davis (1986) on harm versus wrong and Alexander et al. (2009) on culpability.) Given the controversy over what determines the severity of crimes themselves, the difficulty of ranking them in order to assign proportionate penalties becomes even more difficult.

A final problem with retributivist punishment on which economics is particularly well suited to comment is its resource cost. Economists and economics-minded legal scholars have paid very little attention to retributivism; as Posner (1980, p. 92) wrote, it is “widely viewed as immoral and irrational, at least as primitive and non-rational.” (For similar views, see also Kaplow and Shavell (2002) and Sunstein (2005); a notable exception to the antipathy among economists to retributivism is Wittman (1974)). At the same time, legal philosophers have not paid much

attention to the economic ramifications of retributivism, although Avio (1990, 1993), Cahill (2007), and White (2009) have started to look at this issue. The problem with implementing a retributivist system of punishment in the real world is that its perfectionist nature (“the guilty *must* be punished in proportion to their crimes”) does not easily allow for the compromises required in a world of scarcity. If governments tried to punish all wrongdoers according to their just deserts – including making every possible attempt to apprehend and prosecute them – the criminal justice would end up absorbing all of the society’s resources (White 2009; see Braithwaite and Pettit (1990) on system-wide considerations of retributivism). For this reason, some recommend a hybrid theory of punishment with negative retributivism as a limited factor (Avio 1993), a consequentialist retributivism that seeks to maximize some measure of justice (Cahill 2007, 2011), or a “pro tanto retributivism” that considers necessary compromises to result from a balancing of competing principles (White 2011a).

Retributivism remains a vital area of interest and research, with contemporary scholars attempting to refine its principles in the context of a constantly evolving political world (White 2011b) and exploring the implications of new developments in neuroscience and psychology (Nadelhoffer 2013). Although it does not sit well with the utilitarian foundations of the economic approach to law, economists should take note of the extent to which retributivism lies at the root of much of criminal law doctrine and how it steers the criminal justice system away from textbook models of efficiency, affecting resource allocation throughout the criminal justice system and society as a whole. This knowledge is also integral to the way that legal scholars and philosophers understand how retributivism works in the real world.

Risk Management, Optimal

Andrew Torre

School of Accounting, Economics and Finance,
Deakin University, Melbourne, VIC, Australia

Abstract

Individuals continually confront a discrepancy between ever expanding and changing wants and the means that they have at their disposal, time, and income, to satisfy them. One of the consequences is the need to make constrained choices between alternatives that have uncertain outcomes. Risk is a different concept from uncertainty. Individual optimal risk management means reducing, eliminating, or fully bearing risk, after conducting a “cost-benefit” analysis. In practice, however, cognitive biases mean that many decisions are not economically rational, necessitating paternalistic government and judicial interventions. Systemic, or whole financial system collapse risk is, optimally managed using well-designed macroprudential regulatory tools. The source of this type of risk is the inherent dynamics of the financial system over the course of the business cycle, interacting with credit market negative externalities, often as in the case of the GFC, spawned by government regulatory failure.

Synonyms

Financial risk; Operational risk; Systemic risk

Definition

Individually, decision makers optimally or rationally manage operational and financial risk, when they reduce it, eliminate it completely, or fully bear it, after conducting a “cost-benefit” analysis. Systemic, or the risk of whole financial system collapse, which arises due to credit market externalities, is managed optimally by appropriate macroprudential regulation.

Introduction

Risk and uncertainty are distinct economic concepts in economic theory; however, most contemporary microeconomic texts tend to use these terms interchangeably. In a risky situation, a rational decision maker confronts well-defined probabilities, while in an uncertain one, these are not known, or poorly defined (Knight 1921). This entry is only concerned with the management of risky choices, interpreted in an economic framework. Individuals and businesses confront and have to manage operational and financial risks. Attempts are made to minimize the cost of risk using “tangible assets or actions” in the former, and “options on financial instruments or commodities” in the latter case, respectively (Viney 2011, p. 383). In addition, governments need to optimally manage systemic or the risk of total financial system collapse. “Whole system” risk management is particularly topical given the recent global financial crisis (GFC) and its aftermath, which is still very evident in parts of Europe and to a lesser extent in America.

At the outset it should be noted that there is a large “noneconomic” literature on risk management. An example is provided by Ritchie and Reid (2013) in the context of ecotourism businesses. They provide three different definitions gleaned from different sources: first, “The Australian and New Zealand Standard,” which defines risk as “the effect of uncertainty on objectives” (p. 274); second, Glaesser who defines risk as “the product of magnitude of damage and the probability of occurrence” (ibid.); and third, Priest, who “differentiates between real and perceived risk, with perceived risk the best estimate of real risk” (ibid). The authors’ definition of risk is “any threat that will negatively impact an organization’s ability to achieve its objectives and execute its strategies successfully” (ibid.).

Rational Strategies to Deal with Risk

A simple example will enable the reader to see how rational optimizing decisions are made under risk and uncertainty. A risk-averse Amanda is

Risk Management, Optimal, Fig. 1 Simple Decision Tree illustrating Risk and Uncertainty

running a software development business and has to decide whether to develop a piece of software for a new overseas export market. If she succeeds in the export market she gains \$10 m, if not she loses \$2 m. The payoffs \$10 m and \$2 m are equal to the profit from each alternative. If the software is not developed, the business will continue to earn \$5 m a year. The estimated probabilities of success and failure are 0.7 and 0.3 respectively, and Amanda's risk premium is \$0.5 million. It is useful to set out this information in terms of a decision tree that incorporates uncertainty and, in this instance, operational risk as two distinct concepts (Fig. 1).

Operational risk is incorporated into the analysis by adjusting the decision maker's payoffs, while probabilities attached to each of the branches of the lower portion of the decision tree introduce uncertainty. When there is uncertainty, the payoffs become expected values. Since risk is a cost to a risk averter, the risk premium is subtracted from expected profit in each of the payoffs. Expected profit equals: $0.3 (-\$2 \text{ m} - \$0.5 \text{ m}) + 0.7 (\$10 \text{ m} - \$0.5 \text{ m}) = \$5.9 \text{ million}$. Since $\$5.9 \text{ m} > \5 m , the software should be developed even though Amanda is risk averse. The decision would be reversed if the cost of risk was high enough to make the expected profit from exporting $< \$5 \text{ m}$. If Amanda was a risk taker, the \$0.5 m, being a benefit, would be added to each of the payoffs. The expected profit would be

\$6.9 m, which would be $> \$5 \text{ m}$, and the software would be exported. If she was risk neutral, it would not be necessary to make any adjustment to the payoffs, since risk is neither a cost nor a benefit. The expected profit would be \$6.4 m. Again the optimal decision would be to export the software. In Amanda's case, the operational risk is rationally managed by using a decision tree that factors in the probabilities of success (failure) and the cost of risk. This is a form of "cost-benefit" analysis. If the venture fails, she absorbs the expected loss.

Legal Regulation of Operational and Financial Risk Management

The above analysis is predicated on the assumption that decision makers are economically rational; however, human cognitive biases considerably complicate risk management. Thaler and Sunstein (2008) characterize the human brain as having two separate cognitive systems, which are in conflict with each other, resulting in a tendency for irrational to dominate rational decision-making. The first or automatic system is in the words of the authors, "uncontrolled, effortless, associative, fast, unconscious and skilled" (p. 19), while they characterize the second or reflective system as "controlled, effortful, deductive, slow, self-aware and rule following" (p. 20).

As a consequence of this brain anatomy, humans are prone to exhibit a number of cognitive biases in different contexts, which make risk management along the lines of the rational “cost-benefit” model difficult to achieve in practice. There are two responses to this dilemma: government paternalistic interventions and legal regulation. An example of the former would be making the wearing of protective clothing and a mask compulsory for asbestos removal, rather than optional, based on individuals’ assessment of their own risk of subsequent harm.

In addition, judge-made or common law complements government paternalistic policies to assist individuals manage risk optimally. Both contract and torts laws are fundamentally concerned with the issue of whether an actual loss should be allowed to lie where it falls or shifted onto someone else. Torts law differs from contract law in that it regulates non-contractual interpersonal relationships. Specifically, the law pertaining to exemption clauses in standard form contracts and the tort of negligence both address risk management in settings of inequality of bargaining power and high bargaining costs, respectively.

Since the common law of contract is predicated on the principle of freedom of bargaining, there is both judicial and statutory reluctance to interfere with a voluntarily and honestly negotiated allocation of risks between the parties. An example is the specification of the contingencies that impact the promisor’s obligation to perform the contract, such as physical destruction of goods before their delivery date falls due. At common law the general rule is that “prima facie a promisor takes the risk of an event happening, which prevents him from performing his promise” (Scanlan’s *New Neon Ltd v Tooheys Ltd* (1943) 67 CLR 169 at 200 (Latham CJ), cited in Seddon and Ellinghaus (1.107, 2008). However in the case of a sale of goods, s. 12 of the 1958 Victorian Goods Act provides that “subject to contrary agreement a contract to sell specific goods is avoided if the goods perish without fault of either party” (Seddon and Ellinghaus 19.17). As the parties are free to stipulate a different allocation of risk, the common law principle of freedom of contract is preserved.

Fairness in the negotiation process, as such, is not a guiding principle in allocating risks between

the parties, rather “it is the essence of entrepreneurship that parties will sometimes act with selfishness” (Kirby P in *Biotechnology Australia Pty Ltd v Pace*, (1988) 15 NSWLR 130, 132–133, (cited in Paterson (2012), 1.40). This also applies to consumer contracts, as explained by McHugh J in *West v AGC (Advances) Ltd* (1986) 5 NSWLR 610, 621. “I do not see how that contract can be considered unjust simply because it was not in the interest of the claimant to make the contract or because she had no independent advice” (Paterson, 1.40). As long as consumers can choose between competing standard form contracts with different price and term combinations, then these contracts “represent the agreed allocation of risk by contracting parties, and interference in these agreements is likely only to produce inefficient outcomes” (Paterson, 1.60). Rational bargaining implies that expected contingencies are allocated on the basis of the lower-cost bearer or avoider of the risk. In practice, however, higher-cost bearers may be observed subsuming risks due to relatively weak bargaining positions and/or cognitive biases, infecting the negotiating process. A very likely outcome of this incongruity is terms that are unfair and/or inefficient. This issue has been addressed by both the common law and more recently the Australian legislature.

(a) **Exemption clauses in standard form contracts at common law**

Exclusion or limitation clauses are a classic risk allocation and management device found in standard form contracts; examples of these purporting to shift risk include “sold with all faults,” “no warranty given,” “all implied terms excluded,” and “at own risk” (Seddon and Ellinghaus 2008, 10.62). These are efficient (inefficient) if they shift risk onto the party whose precaution plus risk costs are lower (higher). Adopting the Kahneman (2011) formulation, they are unfair if they can be construed as an “exploitation of market power by the promisor to impose a loss on the promisee” (p. 306). In considering exemption clauses in standard-form contracts, the courts have distinguished negotiations between businesses from those between a business and consumer, on the basis of differences

in equality of bargaining power. An example of this judicial dichotomy is found in *Photo Production Ltd v Securicor Ltd* [1980] AC 827, where Lord Diplock wrote at 851: “in commercial contracts negotiated between business-men capable of looking after their own interests, and of deciding how risks inherent in the performance of various kinds of contract can be most economically borne (generally by insurance), it is, in my view, wrong to place a strained construction upon words in an exclusion clause, which are clear and fairly susceptible of one meaning only, even after due allowance has been made for the presumption in favour of the implied primary and secondary obligations” (Clarke et al. 2008, p. 252).

In relation to consumers, while the High Court of Australia (HCA) in *Sydney City Council v West* (1965) 114 CLR 481 has rejected the doctrine that an exclusion clause cannot provide protection against liability for a “fundamental breach,” regardless of how widely it is drafted, the courts have nevertheless “prevented exemption clauses from being used unconscionably against consumers by a rigorous application of the ordinary rules of construction” (Clarke et al., p. 251). Consequently, exemption clauses cannot be used to excuse a “radical breach of the promisor’s obligations under the contract” (*Windeyer J in TNT (Melbourne) Pty Ltd v May & Baker (Australia) Pty Ltd* (1966), 115 CLR 353. HCA (Clarke et al., pp. 256–258). Generally, at common law, the party who wishes to shift risk using an exemption clause has to show that it has been incorporated into the contract and, when correctly construed, is applicable to the situation at hand (Seddon and Ellinghaus, 10.66). An example of a rule of construction is the “four corners rule,” which states that “an exclusion clause will confer protection only in respect of conduct that occurred in the performance of the contract” (Clarke et al., p. 256). Therefore, if a council inserts an exemption clause in a contract of bailment seeking to protect it from loss of, or damage to, parked vehicles, this term will be construed “*contra proferentem*” against the bailee. As such, “it will not protect the Bailee from ‘storing the goods in a place or in a manner other than that authorised by the contract, or if the Bailee consumes or destroys them instead of storing them, or if he

sells them” (*The Council of the City of Sydney v West* (1965) 114 CLR 481, HCA, per Barwick CJ and Taylor J. (Clarke et al., p. 256).

The attack on unfair contract terms has been taken up by the Australian legislature, through its enactment of the Unfair Contract Terms Law (“UCTL”), contained in Pt 2-3 of the Australian Consumer Law (“ACL”), in Schedule 2 to the Australian Competition and Consumer Act 2010 (“CCA”), and Pt 2 Div 2 Subdiv. BA of the Australian Securities and Investments Commission Act 2001 (Cth) (“ASIC Act”) (Paterson 1.10.) Exclusion clauses are regulated under the consumer guarantees law (CGL) (Paterson 13.50). Consumer guarantees, which apply to the supply of goods and services to a consumer, replace the implied terms regime under the now repealed Australian Trade Practices Act (1974), since it was thought that these were too complex and uncertain (Paterson 11.30). The consumer guarantees are to be found in Chapter 3 Pt 3-2 Div. 1 Subdiv. A of the Australian Consumer Law (Paterson 11.80). An example is that the goods will be of acceptable quality, i.e., *inter alia*, free from defects, safe, and durable (Paterson 11.80, 11.90). While the risk of unacceptable quality is *prima facie* borne by the seller, the legislation shifts it onto the buyer in the following circumstances, in which case the purchaser cannot rely on the acceptable quality guarantee. First, defects are specifically drawn to the consumer’s attention; second, they are caused by abnormal use; or third, the consumer should reasonably have become aware of them since they were examined before being bought (Paterson 11.90). Other than in these cases, an exclusion clause inserted into the contract, which purports to exempt the seller from bearing the risk of unacceptable quality, is void under Australian Consumer Law, s 64(1). In addition, it may also be void because it is unfair under the Unfair Contract Terms Law (Paterson 11.180). The tests are different under the two regimes. In the first case, the “court will consider what the term purports to do and its effect,” while in the second, a court “will apply the test for an unfair term” (Paterson 11.180). Under the legislation, unfair terms are characterized as “imbalanced when they attempt to detract from the statutory rights held by consumers” and

therefore “lacking transparency” (Paterson **11.180**). A reasonable interpretation of the common law and reformulated statutory provisions taken as a whole, is that they are increasingly leading to outcomes that satisfy both the fairness and efficiency criteria.

(b) The tort of negligence

Fleming characterizes the function of torts law as ex post social risk management, “the law of torts then is concerned with the allocation of losses incident to man’s activities in modern society, and the task confronting the law of torts is, therefore, how best to allocate these losses in the interest of the public good” (Fleming (1998), p. 3). Torts law achieves this by substituting liability rules, strict liability and negligence, for voluntary bargains between the parties. Since in common law jurisdictions negligence is comparatively much more important, the discussion will focus on this tort. Mendelson, a torts law scholar, interprets this species of action on the case in a risk management framework. She writes, “the rationale for the tort of negligence is two-fold: (1) to enable those wrongfully injured through the negligent conduct of others to obtain compensation from the injurers; and (2) to impose standards based on a duty to avoid creating risks, which may result in an injury to another. If there is no way of avoiding a particular risk, or of predicting whether or not it will materialise, then the risk ought to be disclosed to those who may be harmed by it” (Mendelson, p. 278). “At common law, to be successful in a cause of action in negligence, the plaintiff (victim) has to establish on the balance of probabilities that: (i) the defendant (injurer) owes him or her a duty of care; (ii) the defendant is at fault by breaching the duty of care, by falling below the standard expected of a reasonable person in the defendant’s position; (iii) the defendant’s breach factually caused the plaintiff’s harm and (iv) the harm was reasonably foreseeable” (Mendelson, p. 281).

The second and third aspects of the common law of negligence (principles of breach and causation) have been recently modified by legislation in all of the Australian states. *The Civil Liability Act 1936* (SA), s 32 and 32(2); *Civil Liability Act*

2002 (NSW), s 5B and 5B(2); *Civil Liability Act 2003* (Qld), s 11 and s 9(2); *Civil Liability Act 2002* (WA), s 5B and s 5B(2); *Civil Liability Act 2002* (Tas), s 11 and s 11(2); *Civil Law (Wrongs) Act 2002* (ACT), s 43 and s 43(2); and *Wrongs Act 1958* (Vic), s 48 and s 48(2) each provides that “(1) A person is not negligent in failing to take precautions against a risk of harm unless: (a) the risk was foreseeable (that is, it is a risk of which the person knew or ought to have known), and (b) the risk was not insignificant, and (c) in the circumstances, a reasonable person in the person’s position would have taken those precautions. (2) In determining whether a reasonable person would have taken precautions against a risk of harm, the court is to consider the following (amongst other relevant things): (a) the probability that the harm would occur if care were not taken; and (b) the likely seriousness of the harm; and (c) the burden of taking precautions to avoid the risk of harm; and (d) the social utility of the activity that creates the risk of harm” (Mendelson **2010. 11.1.2, 11.2**).

In a basic sense, these provisions bear some resemblance to the “lower cost precaution taker plus bearer of risk principle.” Study of the cases on negligence, applying common law and the modifying statutory principles, is very valuable because it provides detailed guidance to the difficulties judges face in applying the criteria to complex individual risk management problems that arise in practice and how these might be resolved. The first HCA case to begin interpreting the new legislation, *Adeels Palace Pty Ltd v Moubarak* (2009) HCA 48 (2009) 239 CLR 420, is a good example. “The defendants as occupiers of a reception and restaurant business, owed a duty of care to two men, who while on the premises were shot by a gunman in December 2002. The gunman was one of the patrons, who initially came into the restaurant unarmed; however following a violent altercation on a dance floor, returned with a loaded gun and used it to shoot the plaintiffs” (Mendelson. **11.2.1.1**). “The High court of Australia was asked to decide, pursuant to s 5B of the NSW Civil Liability Act, whether the defendants had failed to take reasonable precautions against the risk posed by the gunman” (Mendelson. **11.2.1.1**). “Since the High Court found that the

plaintiffs had not established causation (see below), the issue was not decided, however the Court did provide guidance on the matter of reasonable precautions” (Mendelson, **11.2.1.1**).

First, given that harm has actually occurred, foreseeable risk has to be assessed before the event or activity occurs and not on the basis of what actually happens if the risk eventuates (Mendelson **11.2.1.1**). In this case, this was the probability of violence occurring at a reception and restaurant business, if “licensed security personnel who would act as crowd controllers or bouncers were not provided” (Mendelson **11.2.1.1**). Second, the foreseeable risk that is managed cost-effectively by taking precautions does not mean “general risks associated with certain activities” (the common law rule) but foreseeability of the specific risk “that called for, as a matter of reasonable precaution, the presence or physical authority of bouncers or crowd controllers to deal with it safely” (Mendelson **11.2.1.1**, p. 337). Third, “there is no liability unless factual causation is established by the plaintiff, and this ‘is determined by the ‘but for’ test: but for the negligent act or omission, would the harm have occurred?” (Mendelson, **12.2.2.1**). In the Adeels case, French CJ, Gummow, Hayne, Heydon, and Crennan JJ found that factual causation had not been established. This was because the evidence did not establish “that security personnel could or would have prevented re-entry by the gunman: a determined person armed with a gun and irrationally bent on revenge” (Mendelson, **12.2.2.1**). Since the court found for the defendants, they had impliedly managed risk optimally.

Credit Market Negative Externalities and Systemic Risk

Financial, or more specifically credit markets, only manage an individual’s or businesses’ financial risk optimally, if none of the cognitive biases infect their choices. However they will not manage aggregate financial risk optimally, because market forces generate financial cycles arising from financial system-induced negative externalities. This stricture also applies even if all decision makers are perfectly rational in the economic

sense. Failures in credit markets give rise to systemic risk, the risk that the entire financial system will collapse. Downturns in financial cycles are known as “balance sheet recessions” and differ from business (inventory or inflation) cycles (BIS 2014, Box 111.A, p. 45; Chapter 4, p. 65). Balance sheet-induced cycles “tend to be much longer than business cycles, and are best measured by a combination of credit aggregates and property prices” (BIS 2014, p. 65). “On average it takes about four and a half years for per capita output to rise above its pre-crisis peak. The recovery of employment is even slower” (BIS 2014 Box 111.A, p. 45).

Rising prices in asset markets (land, housing, and equities) that no longer reflect underlying true determinants of economic value such as land scarcity usually portend emerging and troublesome market bubbles. The cause of the 1930s depression was the bursting of the stock market bubble in 1929 and the widespread bank failures and deflation that followed. High economic growth in the 1920s drove the share market upward, and banks willingly financed most of the purchase price of share portfolios. The latest example of a debt-driven severe economic downturn, and accompanying bank failures caused by bursting bubbles, is the 2008 so called GFC, which began in the United States and then subsequently spread throughout many European economies. Ball (2014) has estimated the weighted average loss in potential output for 23 countries including the United States from the “Great Recession” as being 7.2% in 2013, increasing to 8.4% in 2015 (Greece, Hungary, and Ireland >30% and the United States 5.3%). In terms of 2015 US dollars, the 8.4% loss translates into \$4.3 trillion (Ball 2014, p. 5).

At the dawn of the twenty-first century, another stock market bubble burst. However this was eclipsed by a boom in real housing prices that had emerged in the mid-1990s and led *The Economist* magazine in 2005 to describe it as “the greatest bubble in history” (Garnaut and Llewellyn-Smith, p. 11). In 1999 in America, the Clinton administration wanted to increase home ownership among poorer members of the community. This was to be achieved by lowering interest rates through expansion of the money supply and giving the mortgage providers Fannie Mae

(Federal National Mortgage Association) and Freddie Mac (Federal Home Loan Mortgage Corporation) incentives to make loans to subprime borrowers, who being poor credit risks could not borrow in conventional capital markets (Garnaut and Llewellyn-Smith, p. 20). Incentives included tax breaks and the ability to securitize subprime loans. Securitization is a “practice through which an illiquid but income producing asset is converted into a security more easily traded by investors” (Garnaut and Llewellyn-Smith, p. 41). It “shifts and repackages risk but does not eliminate it” (Garnaut and Llewellyn-Smith, p. 41). “The securitization process was insured often by selling a guarantee called a credit default swap (CDS)” (Garnaut and Llewellyn-Smith, p. 51).

“Credit analysts at JPMorgan invented the CDS” (Garnaut and Llewellyn-Smith, p. 40). A CDS transfers the risk that a debtor will not repay a loan from the creditor to an insurer, in this instance, “risk was shifted from company to company; one paid the other to absorb the risk of default” (Garnaut and Llewellyn-Smith, p. 65). As a consequence, sellers of these instruments were encouraged to take even greater risks, instead of properly managing their balance sheets to ensure that they could meet their financial obligations. “Being over the counter derivatives, these transactions were hidden from regulators and the wider market of investors” (Garnaut and Llewellyn-Smith, p. 66). A CDS is a class of interconnecting derivative. Garnaut and Llewellyn-Smith, p. 66 write: “During the crash of 2008, when confidence was tested, the risk that had been shifted from thousands of individual companies suddenly became a risk to the entire system. Because nobody knew where the risk lay, everyone was suspect.” The crunch came when US Federal Reserve officials pursued a sharp contractionary monetary policy to break the real estate bubble, and the supply of credit rapidly contracted. There was a sharp rise in mortgage defaults and foreclosures. Since securitized mortgages had been bought all over the world, overseas financial institutions and investors were also impacted.

“A principal cause of the GFC was the policies of the U.S. monetary and regulatory authorities” (Stiglitz 2012). Poorly designed government policy and regulatory failure gave critical decision

makers in financial institutions perverse incentives, which contributed to severe credit market failures, and widespread externalized costs. They also fuelled the increasingly irrational speculative activity that was driving house prices upward. Three negative externalities have been identified in the literature: (i) strategic complementarities, (ii) fire sales, and (iii) interconnectedness. The first category arises due to vigorous competition between financial institutions and increasing adverse selection problems, lowering profits from loans as the upswing of the cycle gathers momentum. The outcome is that all institutions tend to engage in the same risky lending practices, thereby acquiring virtually the same “toxic” loan portfolios. Fire sale externalities come into play when the bubble has burst. Widespread asset sales at prices below fundamental economic values during times of financial distress cause asset prices to decline adversely, impacting all financial intermediaries’ balance sheets. The Bank of England describes the source of these two externality categories as “collective overexposure of the financial system in the upswing of the credit cycle, and excessive risk aversion in the downswing” (Bank of England, p. 10). Interconnectedness externalities arise from “the rapid dissemination of shocks between interconnected financial institutions” (De Nicolo' et al. 2012, pp. 4–5). “A network of large multinational based and interlinked financial institutions, while mitigating the impact of small shocks by spreading them, seems to amplify large shocks because they can reach more counterparties” (De Nicolo' et al. 2012, p. 10). According to The Bank of England, the source of this network externality is “the distribution and concentration of risk within the financial system” (Bank of England, p. 15). The role that “interconnecting derivatives” such as CDSs played in transmitting shocks was illustrated in the previous paragraph.

Managing credit market negative externalities optimally, necessitates an absence of government regulatory failure plus macroprudential regulation of the financial system. This differs from microprudential regulation, which is designed to align principal (lending managers)-agent (customers) incentives, given the difficulty agents confront in monitoring principals’ lending activities. An

example of a solution is the minimum capital requirement of Australian banks. “If a deposit taking institution sustains loan losses in excess of its profits, it must write them off against capital, not against liabilities (depositors’ funds). Consequently in order to deal with such a contingency, APRA (The Australian Prudential Regulation Authority) mandates that such an institution must hold at least 8% of its capital base (equity) in a stipulated form: shareholders’ funds and retained earnings (Tier 1 capital), and certain types of preference shares (Tier 2 capital)” (Viney, pp. 89–90). However microprudential regulation does not by itself protect the integrity of the whole financial system. Furthermore, the whole behaves differently from its constituent parts. “Stabilising one institution can destabilise the whole system” (De Nicolo' et al. 2012, p. 7).

There are two ways of classifying macroprudential policy tools. De Nicolo' et al. 2012, p. 11, describe these as: “capital requirements (surcharges), liquidity requirements; restrictions on activities, assets or liabilities, and taxation.” The Bank of England 2011, p. 17, adopts the following groupings: “those that affect: (i) the balance sheets of financial institutions; (ii) the terms and conditions of loans and other financial transactions and (iii) those that influence market structures.” Systemic financial system risk is either time varying, emanating from complementarity and fire sale externalities, or cross sectional, arising from interconnectedness externalities. “Balance sheet and loan restriction tools address dynamic risk, while market structure interventions target cross sectional risk” (Bank of England, p. 17). Generally regulation of capital buffers can potentially ameliorate all three externality categories (De Nicolo' et al. 2012, p. 14). Other examples of regulatory instruments are restrictions on bank asset allocations to limit asset growth in the upturn of the cycle, and adjustment costs in the downturn, (De Nicolo' et al. 2012, p. 12) and the imposition of maximum leverage ratios (Bank of England, p. 17).

Conclusion

In this entry, while financial has been distinguished from operational risk, they are both managed

optimally in the same way, through “cost-benefit” assessments. Doing so will result in risk being reduced, eliminated, or fully borne by the decision maker. In order to implement these “optimization rules,” rational behavior on the part of individuals, which implies an absence of cognitive biases, is necessary. This stringent requirement is rarely met in practice, and government paternalistic risk management is often observed. An example is outright prohibition of the consumption of harmful drugs. In addition, the common law principles of contractual exemption clauses and negligence both complement paternalistic policies. The first does this by targeting unfair risk-shifting contractual terms, while the second assesses, *inter alia*, the adequacy of the respective parties’ precautions, after an accident has occurred.

The optimal management of systemic risk or total financial system collapse requires an absence of government regulatory failure plus robust prudential regulation. An example would be the imposition of capital controls between countries. Unimpeded market forces generating credit market negative externalities will usually fail to ensure that the economy’s aggregate exposure to risk is optimal over the course of the business or inventory cycle. Financial system credit creation, during cyclical upswings, fuels increasing asset prices, balance sheet leverage, and the outcome is excessive exposure to sub-optimal amounts of aggregate risk. Similarly, during the downswing of the cycle, credit withdrawal, deleveraging, and asset price declines can generate disproportionate output and employment losses that are “extraordinarily long lasting” (BIS, p. 7). Furthermore, “financial cycles can go largely undetected. They are simply too slow moving for policy makers and observers whose attention is focused on shorter-term output fluctuations” (BIS, p. 7).

Röpke, Wilhelm

Stefan Kolev

Wilhelm Röpke Institute, Erfurt and University of Applied Sciences Zwickau, Zwickau, Germany

Abstract

The purpose of this entry is to delineate the political economy of Wilhelm Röpke. To reach this goal, a history of economics approach is harnessed. First, the entry concisely reconstructs Röpke's life, intellectual evolution, and heritage. Second, it presents the specificities of his perspective on economic embeddedness focused on the stability of social order and on the role of informal institutions as indispensable stabilizers of this order.

Biography

Wilhelm Röpke (1899–1966) was a key figure within a fascinating generation of European economists. Even though not as widely received today as his colleagues and friends F.A. Hayek (1899–1992) and Walter Eucken (1891–1950), Röpke and his age peers had the mixed privilege to experience two world wars, but also the intellectual privilege to be among the most renowned economists in Europe during the period of the Great Depression as well as in the postwar decades. Röpke's vibrant life, his scholarly achievements as political economist and as social philosopher, but also his seminal role in shaping economic policy at several crucial junctures more than vindicate a detailed portrayal, with the main aim to show how he complements the ordoliberalism of the Freiburg School by his specific research program within the ordoliberal paradigm.

Röpke was born in a small town in the North-west of Germany and retained a lifelong sympathy for rural, small-scale social contexts like the one of his youth. He studied a combination of economics, law, and administrative science at Tübingen, Göttingen, and Marburg. Having

Robbery

► [Piracy, Modern Maritime](#)

completed both a (historicist) dissertation and a (theoretical) habilitation at Marburg, Röpke moved to Jena to become Germany's youngest professor at the age of 24 (Gregg 2010, pp. 7–8; Hennecke 2005, pp. 49–53). After a brief stay at Graz, he received a call to Marburg in 1929 and stayed there until 1933, but had to leave almost immediately after the National Socialist seizure of power because of his perennial outspoken opposition (Nicholls 1994, pp. 56–59; Hennecke 2005, pp. 99–114). Röpke and his close associate Alexander Rüstow (1885–1963) received positions at Istanbul, together with several other German émigrés. Both were eager to come back to Central Europe, and Röpke was lucky to receive a call in 1937 to the Graduate Institute of International Studies in Geneva, where he remained for the rest of his life.

Unlike Eucken or his Viennese colleagues, Röpke was not the type of scholar to form a school of his own (Boarman 1999, pp. 69–73) – instead, he was a highly gifted networker and succeeded soon to set up an international network connecting various European countries, one to be expanded after 1945 to the Americas (Zmirak 2001, pp. 201–206). Röpke and Rüstow were among the most active figures at the Colloque Walter Lippmann in Paris 1938, the birthplace of “neoliberalism” – a term with a history reaching well into the nineteenth century, but now to be used for a reformulation of liberalism by twentieth-century social scientists (Gregg 2010, pp. 82–86; Burgin 2012, pp. 67–78). Along with Hayek, Röpke acted in the immediate postwar years as the second initiator of the 1947-founded Mont Pèlerin Society, a hub for the few remaining liberal scholars, until that point isolated at their individual locations in Europe and the United States (White 2012, pp. 233–238; Kolev et al. 2014). Simultaneously, Röpke functioned as a crucial “spin-doctor” to Ludwig Erhard and was the mastermind behind some of Erhard's strategic plans for postwar Germany under the auspices of the Social Market Economy (Commun 2004; Goldschmidt and Wohlgemuth 2008, pp. 262–264). However, Röpke's enthusiasm for the effects of the “economic miracle” faded away during the 1950s, leading to a deepening

pessimism about the prospects of liberty, in combination with voicing ever-sharper conservative positions on social issues. After the “Hunold affair” within the Mont Pèlerin Society, a fall-out with Hayek and the American fraction in the Society ensued (Plickert 2008, pp. 178–190; Burgin 2012, pp. 137–143), with further detrimental effects for Röpke's weakened health leading to his passing away in February 1966.

Even though not as prominent in today's policy debates in Germany as authors like Eucken or Keynes, Röpke is frequently present in the official addresses of Chancellor Merkel or of finance minister Wolfgang Schäuble. In 2007, the Wilhelm Röpke Institute was established in Erfurt, close to Röpke's first professorship at Jena. Also, Röpke has been more widely received and discussed than Eucken in some other European countries (especially Switzerland and Italy) as well as in conservative circles in the United States (Commun and Kolev 2018).

The Political Economist Is More Than Just an Economist

Röpke's impulses to the research program of the incipient neoliberal movement in the 1930s and 1940s are seminal – and often overlooked today. Despite their worsening relationship in the late 1950s amid the tensions in the Mont Pèlerin Society, Hayek acknowledged how Röpke had realized “early, probably earlier than most of our contemporaries, that an economist who is only an economist cannot be a good economist” (Hayek 1959, p. 26). And this is indeed characteristic for Röpke's oeuvre: in line with Eucken's concept of the “interdependence of orders,” Röpke conceived a theory of the economy as an entity deeply embedded in and interrelated with adjacent social orders (Kolev 2013, pp. 121–136, 2015, pp. 424–427). Two issues are of paramount importance for his specific take on ordoliberal political economy: first his overarching concern with the stability of the economic order as embedded in society, and second his particular attention to what one would call today “informal institutions” – the particular cultural perquisites

and preconditions which to Röpke were more important for enabling stability than the formal legal rules framing the economy (Zweynert 2013, pp. 116–120). His focus on these two domains, stability and informal institutions, provides a valuable complement to the ordoliberal research program of the Freiburg School, and these domains also offer a helpful structure for continuing this exposition.

Stability Is Not to Be Taken for Granted: On the Fragility of the Spontaneous Order

Following up on Hayek's assessment above, Röpke can often be seen as prescient – both in his conceptual apparatus and his theoretical arguments. For example, he used the term “spontaneous order” as a description for the market in 1937, years before it explicitly found its key place in Hayek's terminology (Röpke 1963, p. 4). However, Röpke was also early to express serious concerns about the fragility of this order and to found his political economy on the issues of stability. The initiation was the Great Depression when he conceptualized, within the Austrian Business Cycle Theory, a phase of “secondary depression” during a slump of the economy: here, the useful effects of the “primary depression” with its merits in purifying the economy of the malinvestments of the boom are depleted – and the dangerous aspects of the depression start spreading, as its deflation becomes omnipresent (James 1986, pp. 329–342; Kolev 2013, pp. 178–183). The main danger here according to Röpke is not an economic one, rather it is rooted in the interdependence of the economic and the political order: The popular sentiments of unstoppable downward dynamics can in his analysis delegitimize not only the market economy as an economic order but also democracy as a political order and the free order of society as a whole (Röpke 1932, 1936, pp. 129–132). It was because of this notion of interdependence that Röpke, in contrast to his Austrian friends (Haberler 2000), pleaded in the early 1930s for active policy responses to stop the disintegration of the political order due to illiberal extremisms of various kinds.

Again, Hayek later acknowledged publicly the correctness of Röpke's broad perspective at this key juncture and also confessed his own narrowness in judging the harm of deflation only on purely economic criteria (Magliulo 2016).

In the decades to follow, Röpke expanded comprehensively on this early intuition of the crucial importance of stability in a system of interdependent social orders. In his trilogy published in German during the war (Röpke 1948, 1950, 1959), he searched for a diagnosis of the multiple crises of his age, for a therapy for them in Europe, and also for a solution set for the pressing issues in the international economic relations (Sally 1998, pp. 133–147). He explored a specific normative vision of the market within society, later to be called a “humane economy” in the English title of his probably most well-known book today (Röpke 1960), a vision to be depicted below. In the course of these endeavors, he left technical economics aside and moved increasingly into the domain of social philosophy, a parallel evolution observable in many of his age peers (Blümle and Goldschmidt 2006).

Informal Institutions, Not the Legal Framework Are the Key to Long-Term Stability

While the ordoliberalism of the Freiburg School focuses on the order-generating properties of the formal rules framing the economic process, the specifically Röpkean agenda within the “order in liberty” program of ordoliberalism is differently nuanced. Without disregarding the crucial role of formal legal institutions as a necessary condition for a stable system of social orders, Röpke's political economy did not perceive them as a sufficient condition. Rather, in an implicit division of labor with his Freiburg colleagues, Röpke underscored in his writings the essentiality of what he called the “anthropological and sociological” preconditions or prerequisites of a stable social order with a high degree of social cohesion (Röpke 1950, pp. 191–194, 1960, pp. 74–89). These cultural preconditions are partially ideal (called above “anthropological”) and relate to necessary values within the intellectual heritage of Christianity, and

partially they also have a material side (called above “sociological”) and depict the necessary social structures within which a “humane economy” is possible (Röpke 1960, pp. 222–235). Here an interesting contrast to Hayek can be drawn: while Hayek is primarily concerned with the threat which the logic of the small group can inflict on the mechanisms of the extended order of society, Röpke worries most about the opposite, i.e., about the threats stemming from “enmassment” where the logic of anonymous society uproots the individuals from the contexts of their traditional small communities and their particularly reliable social cohesion (Kolev 2016, pp. 16–20). Correspondingly, retaining and conserving these small contexts both in terms of economy and of society is the central goal of his “humane economy,” thus preventing the individuals from falling prey to ideational vacuum or to unnatural social structures – and as the market tends to use up the resources of its stabilizing pillars, these are to be permanently checked and, if necessary, stabilized anew by the state and other players in civil society (Röpke 1942, pp. 67–71).

This Röpkean plea for specific informal institutions to guarantee stability has often been criticized as romantic, naively conservative, or even “retro-utopian” (Solchany 2015, pp. 484–501). While these critiques for Röpke’s therapies do not fully lack justification, Röpke’s diagnosis regarding the fragility inherent in “spontaneous orders” can claim validity until today, in the global economic order and, most recently, also in the political order of Western societies. It will be intriguing to observe to what extent the age of digitalization with platforms like social media can partially bring back to relevance the logic of small groups and the stabilizing statics which Röpke expected from these groups, in this way possibly providing an antidote to the “too much” of dynamics which discontented fractions of Western societies attest to the processes of globalization.

von Mises (1881–1973), he made major contributions in different areas of economics, especially in the fields of marginal utility theory, welfare economics, monetary theory, business cycle theory, and the history of economic thought. Rothbard's economic theory is comprised in his opus magnum *Man, Economy and State*, published in 1962. The addendum *Power and Market* contains an economic theory of the state. He also made notable contributions in libertarian ethics and anarchist philosophy. He launched and spearheaded the modern libertarian and anarcho-capitalistic movement in the United States and attracted many intellectual followers worldwide, such as Walter Block (born 1941), Gary North (born 1942), Hans-Hermann Hoppe (born 1949), Joseph T. Salerno (1950), and Jörg Guido Hülsmann (born 1966).

Definition

Murray N. Rothbard (1926–1995) was a libertarian political philosopher and an economist in the tradition of the Austrian School of economics.

Life, Work, and Influence of Murray N. Rothbard

Life, Family, and Personal Background

Murray Newton Rothbard was born on March 2, 1926 in New York City as the only child of David and Rae Rothbard, who were Jewish immigrants from Poland and Russia, respectively. Rothbard was born in the Bronx. He and his family later moved to the Upper West Side of Manhattan into a rent-controlled apartment. Rothbard initially went to a public school, where he caused massive trouble for his parents, colleagues, and teachers (Rothbard 1981). After the move to Manhattan, he happily entered Birch Wathen, a private school founded in the early twentieth century. His winning one of the scholarships that were awarded to poor and middle-class boys in order to increase the ratio of boys to girls enabled him to attend (Flood 2008).

Abstract

Murray Newton Rothbard (2 March 1926 in New York City–7 January 1995 in New York City) was a libertarian philosopher and one of the most influential adherents to the Austrian School of economics in the recent past. Building on the economic theory of his mentor Ludwig

Murray Rothbard, with permission from *Mises Institute* in Auburn, AL, USA

After finishing high school, he entered Columbia University in the fall of 1942 at the age of 16. As surprising it might seem in light of his aversion to mathematical economics, Rothbard was at one time in college a statistics major. He was an excellent student and apparently attracted the attention of recruiters for the Manhattan Project. Whether it actually led to a job offer or not is unknown. Rothbard was found to be unfit for military services (4-F) which exempted him from the draft during World War II (Flood 2008). He graduated in 1945 and enrolled in a graduate course in mathematical statistics with the famous statistician and economist Harold Hotelling (1895–1973), who was at the time a member of the faculty at Columbia University (1931–1946). However, disillusioned with Hotelling's lectures, he walked "out of the world of statistics, never to return" (Rothbard 2006, pp. 28–29). His main interests shifted to the social sciences. In 1946 he received the M.A. degree in economics.

According to Rothbard, growing up as a middle-class Jew in the 1930s and 1940s in New York City meant that literally everybody he knew – "friends, relatives, acquaintances, whatever — was either a Communist Party member or else was thinking about whether they should join it." He had "four aunts and uncles who were

Communist Party members and another two or three or four were pondering whether or not to join" (Rothbard 1981). His father had significant influence on him at that time as he was strongly opposed to the Communist Movement. So was Rothbard. In retrospect, he called his father "the first libertarian he knew" (Rothbard 1981). His parents met at an anarchist dance, and at some point his father probably was an active anarchist but decided to stop political action, when he found out that his friends, who were strongly opposed to World War I, had been arrested. From then on, he focused solely on his work as a chemist. One of the first books on anarchism that Rothbard read from the library of his father was Paul Eltzbacher (1908). He found it to be interesting and "exotic." However, he was not yet converted to anarchism as he was only about 10 years old (Rothbard 1981). This would happen some years later.

Rothbard was elected a member of *Phi Beta Kappa* and remained at Columbia University to pursue a Ph.D. in economics under the economic historian Joseph Dorfman (1904–1991). His thesis was entitled *The Panic of 1819* (Rothbard 1962) and it is until today the standard work on this particular economic crisis (Gordon 2007, p. 12). It took 10 years until he was awarded the doctorate degree in 1956 due to disagreements between Arthur Burns (1904–1987) and Dorfman. Burns, then professor at Columbia University and chairman of the Council of Economic Advisors (1953–1956), later chairman of the Federal Reserve (1970–1978), and ambassador to West Germany (1981–1985), lived in the same building as Rothbard. David Rothbard asked him to have a look at his son at the university, but it was Burns who brought his academic career to a virtual halt by telling Dorfman that he would "expect much more from Rothbard." JoAnn Schumacher, who became Rothbard's wife and close collaborator, found him one day sobbing at the doorsteps of his house, disheartened by Burns' obstacles (Flood 2008). Arthur Burns, Wesley Clair Mitchell (1874–1948), and John Maurice Clark (1884–1963) were among the most important professors at the faculty. They looked skeptically at economic theory and accepted the

institutionalist doctrine which conceives of economic theory as only relative to particular historical situations but not as universally true. Rothbard followed Columbia philosopher Ernest Nagel (1901–1985) and his criticism of institutionalism for its opposition to economic theory (Gordon 2007, pp. 9–11). This was an insurmountable conflict between Rothbard and Burns. It was not the only time that he was facing intellectual opposition. However, he would rarely compromise and deviate from a position that he deemed correct.

When Rothbard entered graduate school, there were a peak number of students due to the returning troops, the vast majority of which were social democrats or even communists and in any-way disapproved of the free market. At that time George Stigler (1911–1991), later Nobel Prize laureate (1982) of the Chicago school of economics, arrived at the campus (1947–1958). His first two lectures were on the evils of rent control and minimum wages, which led to some hysteria among the students (Rothbard 1981). To the intellectual relief of Rothbard, Stigler was not averse to economic theory. Through one of his pamphlets, written together with Milton Friedman (1912–2006) (Stigler and Friedman 1984), Rothbard encountered the Foundation for Economic Education. He contacted the group and made the acquaintance of founder Leonard E. Read (1898–1983); F. A. Harper (1905–1973), founder of the Institute for Humane Studies in 1961; and most importantly Ludwig von Mises (1881–1973), who immigrated to the United States in 1940. His radical defense of the free market, and in particular his book *Human Action*, published in 1949 had a profound effect on Rothbard's thinking. Rothbard participated regularly in Mises's seminar at New York University, for which he delivered a number of articles which were partly published in his later works. Mises became Rothbard's mentor, although they would not agree on everything, for example, the proper role of the state. Mises, as a classical liberal, advocated a state strictly confined to the protection of private property rights through a court and police system. Rothbard, however, went one step further and denied the necessity of the state

altogether. In this persuasion he was influenced by nineteenth-century individualist anarchists, such as Lysander Spooner (1808–1987), Benjamin Tucker (1854–1939), and Gustave de Molinari (1819–1912) (Gordon 2007, p. 13).

In terms of economic theory, Rothbard and Mises would only disagree on minor aspects but generally appreciate and admire each other's works. The William Volker Fund, which gave financial support to classical liberal scholars, commissioned Rothbard to write a textbook, which would explain Mises (1998) to college students. Something much larger would originate out of this project – his opus magnum *Man, Economy and State*, published in 1962, one of the most important contributions to Austrian economics in the past century (Hoppe 1999). Ludwig von Mises called Rothbard's treatise:

an epochal contribution to the general science of human action, praxeology, and its practically most important and up-to-now best elaborated part, economics. Henceforth all essential studies in these branches of knowledge will have to take full account of the theories and criticisms expounded by Dr. Rothbard. (Mises 1962)

Only one year later, in 1963, appeared *America's Great Depression*, in which Rothbard applied *Austrian Business Cycle Theory* as laid down by Mises (1912) to the great economic crisis of the 1930s. He worked for different institutions and foundations and published scientific and non-scientific articles, comments, and reviews in various journals and magazines. From 1966 to 1986, Rothbard taught economics at the Brooklyn Polytechnic Institute, an engineering school without a major program in economics.

Although Rothbard was an agnostic and a secularist, he became a columnist for a little right-wing magazine written for protestant ministers called *Faith and Freedom* under the pseudonym Aubrey Herbert. He was criticized by the constituents for being a communist, as he was opposing the Eisenhower administration for its “statist plans” and “attacking the idea that we should spend every drop of American blood supporting Chiang Kai-shek” (Rothbard 1981). Rothbard was against military interventions and conscription, and he favored the free market in all areas of

social cooperation. This is why he in fact considered himself to be an extreme version of the members of the “Old Right,” a movement that evolved in reaction to American entry into World War I (1917), and the New Deal (1933–1938), which Rothbard identified in his book *The Betrayal of the American Right*. The “Old Right” included authors and journalists, such as Albert Jay Nock (1870–1945), H. L. Mencken (1880–1956), Garett Garrett (1878–1954), Robert Taft (1889–1953), Frank Chodorov (1887–1966), and John T. Flynn (1882–1964) whose works played a crucial role in Rothbard’s intellectual development. It was not the only time that Rothbard was red-baited by people on the Right, since, although being an ardent critic of communism, he opposed the global military campaign against it. In his opinion, the battle should be won intellectually and not by means of violent force, and it should be fought against statism in general and not communism in particular. Rothbard even cooperated with members of the New Left in the 1960s looking for allies in his fight against war. For him, this became the most important issue of all. As he noted privately in 1956: “I am getting more and more convinced that the war-peace question is *the key* to the whole libertarian business” (as cited in Payne 2005). Rothbard appreciated the works of New Left historian William Appleman Williams (1921–1990) and in particular his foreign policy analysis and his advocacy of decentralization in domestic affairs. In retrospect, however, he thought that the alliance with the New Left was a mistake. He wrote:

We came to realize that, as Marxian groups had discovered in the past, a cadre with no organization and with no continuing program of “internal education” and reinforcement is bound to defect and melt away in the course of working with far stronger allies. The libertarian groupings would have to be rebuilt as a self-conscious movement, and its major emphasis would have to be on nourishing, maintaining, and extending the libertarian cadre itself. (Rothbard 2007, p. 202)

This is exactly what Rothbard did toward the end of his career. He published *For a New Liberty: The Libertarian Manifesto* in 1973, in which he applied libertarian philosophy to the social and economic problems of our time and thereby

founded the modern libertarian movement (Block and Rockwell 1988). His philosophical opus magnum *The Ethics of Liberty* appeared in 1982. In addition to his contributions in economic theory and philosophy, he wrote a four-volume history of colonial America, *Conceived in Liberty*, and a two-volume *Austrian Perspective on the History of Economic Thought*, tracing the history of economics from the ancient Greeks to the classical economists, such as Adam Smith (1723–1790) and David Ricardo (1772–1823), as well as the French school of classical liberalism and Marxism. He was working on a third volume on more recent developments at the time of his death. He did not finish it.

Rothbard only obtained a full professorship in 1986, as S. J. Hall Distinguished Professor of Economics at the University of Nevada, Las Vegas (UNLV), a university without a graduate program in economics, which meant that throughout his academic career Rothbard was prevented from claiming a single doctoral student as his own (Hoppe 1999). At UNLV, he closely collaborated with Hans-Hermann Hoppe, one of his most influential disciples, until his death on the 7th of January 1995. Despite his unconventional and radical beliefs, he probably could have obtained a full professorship earlier in his career. However, according to Gary North (2010), he suffered from phobia about leaving Manhattan Island, which he could only overcome toward the end of his life.

Academic Work and Influence

Murray N. Rothbard published his opus magnum in the area of economics, *Man, Economy and State*, in 1962, as a relatively young economist of only 36 years. With this volume, he occupied a very, if not the most, influential position within the tradition of the Austrian School of economics in the second half of the twentieth century – although Nobel Prize-winning economist Friedrich August von Hayek (1899–1992) is commonly considered to be the most important representative of this school of thought. However, Hayek is strictly speaking not an adherent to the rationalist mainstream of Austrian economics as espoused by Carl Menger (1840–1921), Eugen von Böhm-Bawerk

(1851–1914), Ludwig von Mises, and Murray N. Rothbard but rather its explicit opponent. He stands in the tradition of British empiricism and skepticism (Hoppe 1999). Like his intellectual forerunners, Rothbard is an “outspoken rationalist and critic of all variants of social relativism: historicism, empiricism, positivism, falsificationism, and skepticism” (Hoppe 1999, p. 223). Rothbard interpreted economic theory as universally and *a priori* true and not only hypothetically valid. In his opinion, it is not subject to constant empirical testing against data. In other words, propositions in economics concern non-hypothetical relations and assume apodictic validity. As Mises in his *Human Action*, Rothbard deduced all his economic propositions from basic axioms. He wrote in the preface to the second revised edition of *Man, Economy and State*:

The present work deduces the entire corpus of economics from a few simple and apodictically true axioms: the Fundamental Axiom of *action* – that men employ means to achieve ends, and two subsidiary postulates: that there is a *variety* of human and natural resources, and that leisure is a consumers’ good. (Rothbard 2009, p. lvi)

Rothbard interpreted economic theory as the logical deduction from the proposition that men act. It is impossible to deny this fundamental axiom without running into a performative contradiction, since arguing against it would imply an act as described above – the conscious employment of means, i.e., once vocal chords, to achieve an end, i.e., the refutation of the axiom of action. It is therefore indisputably true. The validity of economic theory, therefore, rests solely on the validity of the axiom of action and the correct exercise of logical deduction and inference (Hoppe 1999). Hence, empirical testing of economic propositions becomes unnecessary. Economic data can illustrate the propositions but neither verify nor falsify them. Furthermore, Rothbard followed the strict epistemological and methodological individualism of Menger, Böhm-Bawerk, and Mises, that is, he acknowledged the necessity to explain all economic phenomena in terms of purposeful individual action. Only individuals have desires, and “[e]very ‘holistic’ and ‘organistic’ explanation must be categorically rejected as an

unscientific pseudo-explanation” (Hoppe 1999, p. 224). Since human beings act under uncertainty, human action is always speculative, and therefore Rothbard considers mechanical explanations of social phenomena as inappropriate and unscientific. Human action is fundamentally different from the behavior of atoms and other objects considered in natural sciences.

Beyond Mises’s framework, Rothbard made several contributions to Austrian economics. One of the most important is his clarification of marginal utility theory as well as the reconstruction of welfare economics and the theory of the state that he derived from it. Rothbard explained that the word “marginal” does not refer to increments of utility, but rather to the utility of increments of a good. The former would imply measurability of utility, whereas the latter does not. Increments of a good can be characterized in physical terms and can be measured. Utility, however, is completely subjective, cannot be measured, and exhibits only an ordinal character on one-dimensional subjective preference scales. It is furthermore subject to changes over time. Consequently, interpersonal utility comparisons and the application of the rules of arithmetic to the concept of utility are impossible, such as adding utilities together to obtain a measure of “social welfare.” Rothbard took this logical conclusion from the subjective and ordinal character of utility seriously and developed a new version of welfare economics “based on the twin concepts of individual self-ownership and demonstrated preference” (Hoppe 1999, p. 228).

Self-ownership means that every person owns, or exclusively controls, his or her physical body. In every action the personal physical body serves as a means to achieve some end. Thereby, it is demonstrated that the physical body is valued as *good*, and furthermore by doing one thing rather than another, it is demonstrated what is deemed the most highly valued end. In other words, the underlying ordinal preferences are demonstrated. Trading good A against good B demonstrates that good A is ranked higher on the subjective preference scale. For the trading partner, the opposite is true. Both parties expect to benefit from the transaction; otherwise it would not take place. As long

as individuals act, trade, and cooperate voluntarily and do not harm third parties, we might speak of Pareto-superior changes that lead to increases in subjective utility and hence in “social welfare.” If transactions are brought about through coercion, at least one party is made worse off; otherwise it would have engaged in the transaction voluntarily. These changes are not Pareto superior. And it cannot be claimed that they lead to increases in social welfare, since losses and gains in utility cannot be compared. Noncontroversial examples would be criminal offenses, such as robbery and theft. However, also acts of the government, at least in part, classify as coercive. In fact, the power to coerce is the decisive characteristic of the state. Rothbard defined the state:

as that organization which possesses either or both (in actual fact, almost always both) of the following characteristics: (a) it acquires its revenue by physical coercion (taxation); and (b) it achieves a compulsory monopoly of force and of ultimate decision making power over a given territorial area. (Rothbard 2002, p. 172)

Rothbard’s conclusion is the refutation of the institution of government on welfare economic grounds. This of course made Rothbard an intellectual outlier, although his conclusion was implicitly accepted by many academics. As Hans-Hermann Hoppe points out:

Scores of political philosophers and economists, from Thomas Hobbes to James Buchanan and the modern public-choice economists, have attempted to escape from this conclusion by portraying the state as the outcome of contracts, and hence, a voluntary and welfare-enhancing institution. (Hoppe 1999, p. 231)

Rothbard, however, would agree with Joseph Schumpeter (1883–1950) that “the theory which construes taxes on the analogy of club dues or of purchase of services of, say, a doctor only proves how far removed this part of the social sciences is from scientific habits of mind” (Rothbard 1997, p. 247; as cited in Hoppe 1999, p. 231).

Rothbard’s monetary theory is also strongly influenced by the pioneering work of Ludwig von Mises. As he stated: “The Austrian theory of money virtually begins and ends with Mises’s monumental *Theory of Money and Credit*”

(Rothbard 1997, p. 297). However, Rothbard made some additions and in particular generalized the Misesian theory by adopting a broader definition of the supply of money – “money includes whatever is redeemable at par in standard money” (Gordon 2007, p. 39). Mises introduced the so-called regression theorem which states that money as a generally accepted medium of exchange originates as a commodity money, such as gold, in the course of voluntary exchange and cooperation on the market. Rothbard added a theory of the destruction or devolution of money by the government that Hoppe called a “progression theorem” (Hoppe 1999, p. 237). Rothbard (2010) is an exposition of this theory and his views on money accessible for laymen and the general public. Rothbard (2008) and *The Case against the FED* (1994) contain similar ideas.

Rothbard applied Austrian business cycle theory, as formulated by Mises (1912) and Hayek (1967), to the Great Depression of the 1930s in his 1963 book *America’s Great Depression*. Another source of influence for this volume was (Robbins 1971). In fact, Rothbard wrote in a letter to Ivan Bierly in 1959 that he considers Robbins’s book to be “one of the great economic works of our time... This is unquestionably the best work published on the Great Depression” (as cited in Gordon 2007, p. 42). Rothbard shows how the available empirical data supports the Austrian claim that artificial credit expansion leads to an inflationary boom, during which malinvestments are made, and the subsequent bust, in which the “cluster of business errors” becomes apparent (Rothbard 2000, p. 8). When central banks lower interest rates artificially, they make more investment projects look profitable than the subsistence fund, that is, the amount of real savings in the economy, can actually sustain. Hence, the structure of production is changed in an unsustainable manner as more investment projects are started than can be finished. The crisis constitutes the period, in which the necessary corrections take place, i.e., unprofitable investment projects are liquidated and, if not lost altogether, the remaining capital is reinvested into profitable lines of production. In Rothbard’s own words:

In sum, businessmen were misled by bank credit inflation to invest too much in higher-order capital goods, which could only be prosperously sustained through lower time preferences and greater savings and investment; as soon as the inflation permeates to the mass of the people, the old consumption–investment proportion is reestablished, and business investments in the higher orders are seen to have been wasteful. Businessmen were led to this error by the credit expansion and its tampering with the free-market rate of interest.

The “boom,” then, is actually a period of wasteful misinvestment. It is the time when errors are made, due to bank credit’s tampering with the free market. The “crisis” arrives when the consumers come to reestablish their desired proportions. The “depression” is actually the process by which the economy adjusts to the wastes and errors of the boom, and reestablishes efficient service of consumer desires. The adjustment process consists in rapid liquidation of the wasteful investments. Some of these will be abandoned altogether (like the Western ghost towns constructed in the boom of 1816–1818 and deserted during the Panic of 1819); others will be shifted to other uses. (Rothbard 2000, pp. 11–12)

The current financial and debt crisis exhibits the same tendencies again. The ghost towns around Madrid in Spain are only one dramatic case in point for the wasteful employment of capital in the recent past. The current crisis has led to an increased interest in the Austrian theory of the trade cycle among laymen and professional economists alike, both in order to support and to criticize it (see, e.g., Caplan 2008). It is argued that the Austrian theory has more explanatory power than mainstream Neoclassical, Monetarist, or Keynesian accounts of the current crisis, which makes it attractive for young economists, but also a challenge for economists of other schools of thought. Rothbard’s work and influence has played a major role in this development.

Rothbard was cofounder of the *Ludwig von Mises Institute* in Auburn, Alabama, together with Llewellyn H. Rockwell Jr. (born 1944) and Burton Blumert (1929–2009). Today, the institute promotes the ideas of Ludwig von Mises and Murray N. Rothbard as well as their intellectual followers more effectively than ever before. Its website, www.mises.org, makes a large number of books, journal articles, and other writings available for free. There exist a number of professional

journals and periodicals published by the institute, including *The Journal of Libertarian Studies* (1977–2008) and *The Review of Austrian Economics* (1987–1998), for both of which Rothbard served as editor, as well as *The Quarterly Journal of Austrian Economics* (since 1998), which was started after Rothbard’s death. Many of the contributors to the journal see themselves in line with Rothbardian economics. Rothbard himself, however, “by 1963 had grown discontented with economic analysis as an end in itself” (as cited in Casey 2010, p. 7) according to Gary North. Through his many radical writings in the area of libertarian ethics and philosophy as well as his political activism, for example, in support of the Libertarian Party (since 1971), Rothbard launched and spearheaded the modern libertarian and anarcho-capitalistic movement in the United States. Today, it has found followers all around the world.

Rueff, Jacques

Adrien Lutz

GATE L-SE, Université Jean Monnet,
Saint-Étienne, France

Abstract

Jacques Rueff was a French economist with long experience in combining practice and theory. Deeply interested in epistemology and interdisciplinarity, Rueff was a monetary specialist and one of the leading European economists after World War II.

Biography

After studying at the École Polytechnique, **Jacques Rueff** (1896–1978) became an inspector of finance (1923–1926), special advisor to the League of Nations (1927–1930), financial attaché at the French Embassy in England in charge of the Bank of France's sterling reserve (1930–1933), deputy-director of the Mouvement général des fonds (previously the French Trésor; 1934–1939), and deputy governor of the Bank of France (1939–1941). Rueff also participated in the Walter Lippmann colloquium in 1938 (Lane 1997).

Until 1952, Rueff was deeply involved in the postwar negotiations (he was, for instance, the president of the inter-allied reparations agency). A strong advocate of European integration, Rueff was a judge of the Court of Justice of the European Communities (1952–1962). He also became an important economic advisor to

President Charles de Gaulle from 1958, and it was thanks to his plan (with Pinay) that France succeeded in balancing the budget and ensuring the convertibility of the franc. A proponent of a return to the gold standard, Rueff argued against inflation which he always considered a “false right.” He later became a member of the Economic and Social Council.

Innovative and Original Aspects

Deeply interested in epistemology and interdisciplinarity, Rueff adopted a conventionalist methodology (Frobert 2009, see also Claassen 1967), applying this to topics such as unemployment (1925b, 1926, 1931a, b) and money (1927, 1953, 1961, 1963, 1965, 1971, 1973), and being among the first to consider economics as a statistical science (1925a, [1929] 1961). Surprisingly, although his earliest work did not directly express an interest in law (1922), many legal theorists commented on his work long before he became famous for his concept of the “false right” (1945).

The English translation of Rueff’s *From the Physical to the Moral Sciences* ([1922] 1929) was widely discussed in American journals of law and philosophy. According to Rueff, economics is a moral science, all physical and moral sciences use the same tools, and all have a rational branch and an experimental branch. Although their objects, of course, differ, the aim remains always to discover the underlying laws of observed phenomena. Ironically, in this book, he never addressed the questions of law.

Practice and learning in American law had come under strong criticism in the nineteenth century, with particular emphasis on the quasi-mechanical application of its various laws and codes. Lawyers concerned with these issues turned to Rueff’s work on economics and morality for an account of how a social science could be considered a “real science” like physics, constrained by the adoption of a scientific method. Discussion arose concerning what might be the

scientific basis of the concept of law, whether social norms and the evolution of society should be taken into account in attempting to define that concept, and if so what methodology ought to be adopted.

Thus, a preface to Rueff’s work was written by H. Oliphant (1884–1939) and A. S. Hewitt (1902–1987), teachers of law at Columbia and Johns Hopkins University respectively, and fervent advocates of interdisciplinarity particularly with respect to law and economics. From this preface, it was clear that Oliphant and Hewitt accepted that law could be a science on the condition that it applied a rigorous method, allowing case studies. Specifically, Oliphant (1923, 1928) argued in favor of a rapprochement of law and economics, since both aimed to establish a method that combined logic and experience, just as outlined by Rueff. According to them, when a society evolves, this means in terms of logic that one of its first premises has changed. For instance, in several countries, the abolition of the death penalty had only recently become conceivable, and abolition had not been discussed at all in their earlier history. It was therefore necessary to modify the legal texts in such a way as to follow the social changes. These American lawyers lacked a theoretical corpus, however, and this was why Rueff was so widely discussed. His incursions concerning morality strongly interested them, particularly because, for Rueff, manners and laws are valid only for a time.

Impact and Legacy

Law and economics become combined in Rueff’s famous concept of the “false right.” Rueff’s starting point is the concept of the “property rights,” which is rooted in the 544th article of the French civil code: “ownership is the right to enjoy and dispose of things in the most absolute manner, provided they are not used in a way prohibited by statutes or regulations.” Rueff’s *Social Order* (1945) argues that economics is not the science of wealth as has generally been thought, but

rather the science of the links between desired things and men's desiring those things. Wealth does not lie in the things desired but in our ability to enjoy and dispose of things.

As recently remarked by Minart (2016), according to Rueff the lawyer gives shape to the right to property, the economist provides its content, and the police its protection. The right to property is analyzed as a recipe for value. In this respect, a real right is a right that enables a seller to "empty" the content of his right to property "onto" a specific commodity and, in return, to "fill" his right with money. The buyer and the seller agree on the price, and then the right becomes real. And, to the contrary, a false right occurs when the value of wealth contained in this right does not comply with the amount of money the seller wishes to receive – in the case, for instance, of prices being fixed by a public authority.

According to Rueff, prices determine the volume of the right. If the selling price is lower than the purchase price, the volume of the right decreases. There follows an imbalance between supply and demand, and thus the creation of false rights. Such an imbalance is the basis of inflation. The same is also true for unemployment insurance, since it interferes with the free functioning of the price mechanism.

Having successfully combined theory and practice throughout his life, Rueff has made significant contributions to the field of economic analysis through his monetary analysis and his innovative false rights theory. Jacques Rueff remains in many respects one of the major French economists of the twentieth century.

Rule of Law

²Department of Economics, George Mason University, Fairfax, VA, USA

Abstract

This entry explores the role of the rule of law in a market economy. The emergence of the rule of law is a *precondition* of not only political and economic liberty but also economic growth and overall human progress. The presence, or lack thereof, of the rule of law determines whether human interaction will be positive-sum or negative-sum in nature. We explore first the fundamental attributes to the rule of law in relation to property rights and entrepreneurship. Second, we discuss in detail three attributes to the rule of law that generate this productive entrepreneurial process: (1) generality, (2) predictability, and (3) equality.

Introduction

Simply put, the rule of law refers to the absence of political or legal privilege among market actors *and* the absence of arbitrary discretion among political actors. It is a political–legal principle, whereby the governing authority of a particular society is restricted to enforcing laws applied equally to all *and* not intended to benefit one particular party at the expense of another. Any violation of the rule of law implies that political–legal privileges cannot be granted without simultaneously granting discretionary power to those political actors who are in the position to grant such privileges. Therefore, the presence, or lack thereof, of the rule of law determines whether human interaction will be positive-sum or negative-sum in nature.

The Rule of Law, Property Rights, and Entrepreneurship

According F.A. Hayek, one of the leading economists and legal scholars of the twentieth century, “the gradual transformation of a rigidly organised hierarchic system into one where men could at least attempt to shape their own life, where man gained the opportunity of knowing and choosing between different forms of life, is closely associated with the growth of commerce” (1944 [1994]: 18). Such a gradual transformation can be framed in terms of an inherent link between the rule of law, property rights, and entrepreneurship. The presence, or lack thereof, of economic development cannot be explained by an abundance or shortage of entrepreneurship in a society (see Baumol 1990; Boettke and Piano 2016); individuals are always and everywhere on the lookout for previously unnoticed profit opportunities (Kirzner 1973). However, whether or not such a pursuit of profit opportunities manifests itself as productive activities, such as trade and innovation, or unproductive activities, such as rent-seeking and theft (Tullock 1967), depends upon the allocation of entrepreneurial talent in a society (Murphy et al. 1991). Such an allocation is dependent upon the establishment of well-defined and well-enforced private property rights that can be exchanged via money prices, allowing entrepreneurs to calculate the relative scarcity of resources through the guiding signals of profit and loss. Such guiding signals communicate to entrepreneurs whether or not resources have been allocated to their most valued consumer uses (Mises 1920 [1975]). Both the productive allocation of entrepreneurship and the productive allocation of resources via exchange and innovation that follows from entrepreneurship require that property rights restrict competition only to profit-seeking that creates social wealth, not rent-seeking that destroys social wealth (see Boettke and Candela 2014b). Such a restriction, however, implies the presence of the rule of law, without which entrepreneurship will be negative-sum rather than positive-sum. Following Hayek (1960: 205–210), there are three attributes to the rule of law that generate this productive entrepreneurial process: (1) generality,

(2) predictability, and (3) equality. We discuss each of these attributes below in relation to property rights and entrepreneurship.

Generality

To understand the way in which laws are general and abstract, rather specific and concrete, it is important first to make a distinction, following James Buchanan, between the rules of the game and interaction within the rules of the game. The distinction we make between the rules of the game and social interaction within rules follows a “law and economics” approach (Marciano 2016; see also Wagner 2016). Law and economics analyzes, in a world of positive transactions costs, the degree to which different legal rules, particularly the absence or existence of the rule of law, affect economic performance, namely by ameliorating or exacerbating the costs of defining property rights and facilitating exchange. This approach is related, though distinct, to “the economic analysis of law.” Although the terms are sometimes used interchangeably, the economic analysis of law approaches legal analysis by assessing the efficiency of legal rules in a world of zero-transactions costs.

The attribute of generality implies that the rule of law operates as a “meta-legal doctrine” (Hayek 1960: 206), through which the types of laws that are filtered through the legislative process are those that are *end-independent* and *impersonal*. Laws that are consistent with the rule of law must neither command any specific purpose upon individuals nor does it assign any concrete status or outcome that differentiates individuals before the law. This does not mean that laws that recognize individuals on the basis of sex, race, or creed violate the rule of law; rather, it is only when such groups are preassigned a special status or privilege at the expense of other individuals that the rule of law is violated. This violation occurs in a twofold manner. First, resources and income are transferred by force to the politically privileged to the expense of the politically disenfranchised. For example, import tariffs on particular goods lead to the loss of consumer surplus and generate rents for

domestic producers of that good. Secondly, and more importantly, the political transfer from one party to another cannot occur without simultaneously granting discretion to the political official, who must exercise arbitrary force in making such a transfer. When the rule of law is violated, the legislator is no longer “blind,” but can in fact foresee how and to whom laws will effect particular groups of individuals in society. As a result, entrepreneurship in such a society will mutate from profit-seeking to rent-seeking, as entrepreneurs will expend resources to capture privileges through political exchange, which wastes resources that could have otherwise been used for productive innovation (Harnay and Marciano 2011).

Predictability

The rule of law does not assign marching orders to individuals but acts like traffic signals that guide the interaction of individuals in a noncoercive manner. Like traffic signals, they do not rely on legislators directing any other individual in advance, by force, or how to act explicitly. Rather, because individuals can reliably expect that laws will not be changed arbitrarily, “planning” is left to the individual at a particular place and time. Predictability, however, implies neither the complete lack of change in the law nor the absence of a judiciary. Rather, it only implies that laws will be changed on the margin by judges to facilitate coordination between contesting parties according to the circumstances of place and time. Such evolution in the law will be marginal, but adaptive for the adjudication of new disputes, yet consistent with the body of judicial precedent. Therefore, if rule of law is in place, entrepreneurs can reliably feel secure in their property and be able to deploy their resources in long-term investment projects that are productive and wealth-creating. Predictability means laws are intended for such a duration that no one, not even the legislator, can anticipate who will benefit from such laws. It is in this sense that the rule of law operates as a “fifth factor of production” (Boettke and Candela 2014a), providing the framework for

the coordination of the land, labor, and capital by entrepreneurs according to their foresight about future profit opportunities. This has important implications for entrepreneurship and economic development. First, entrepreneurs in the marketplace can reliably “predict,” or anticipate, that they will only be harmed by the threat of losses from competing entrepreneurs, without fear of being harmed by the threat of public predation in the form of outright theft or regulation that bars them from entry into the marketplace. The unintended consequence of the rule of law, then, is to discipline entrepreneurs to accrue profits only by innovating, lowering costs, and producing resources according to consumer preferences. When the rule of law is violated, the only “predictability” that entrepreneurs have in their ability to accrue profits is to bar their competition from entry into the marketplace via capture of monopoly privileges.

Equality

The link between the predictability of laws and the spontaneity of the market process is the attribute of equality before the law. Under the rule of law, laws are applied equally to all, both to the ruler and the ruled. Social interaction and the outcomes of such interactions are guided horizontally by voluntary contract between individuals within the game, not vertically by capturing legal status or manipulating political officials to “bend the rules” in an individual’s favor. Thus, under the rule of law, one’s relative wealth or status in society is not predetermined by privilege; rather, it is *discovered* by learning how best to serve their fellow man via contractual exchange and innovation. In this capacity, government only acts as a referee, or umpire, to enforce the law, setting the precondition within which not one but multiple purposes and plans can be pursued by individuals via trade and exchange. Equality before the law is crucial to entrepreneurship and economic development because it recognizes that individuals are different and unique in their talents, potentialities, and knowledge of a particular time and place. It is freedom from legal discrimination that allows the

spontaneous interaction of diverse individuals to generate entrepreneurial discoveries that are accidental and previously unforeseen. How could Malcolm McLean have applied his unique knowledge of trucking and shipping to pioneer the container ship in the 1950s if he was legally barred by shipping regulations? (see Levinson 2006) The rule of law cannot be violated without the tendency of substituting the rule of men. Under the rule of law, profits and losses in the marketplace are determined by the ability of entrepreneurs to serve consumers. Under the rule of men, profit and losses are determined by the ability of entrepreneurs to win political privileges, which come at the expense of the consumer.

[W]e may say that the movement of the progressive societies has hitherto been a movement *from Status to Contract*—Henry Sumner Maine (emphasis original, 1861 [1982]: 170)

Introduction

The most incredible fact in recent economic history is the rapid decline of extreme poverty throughout the developing world. According to the World Bank, the percentage of individuals living on less than two dollars per day has fallen from 37% in 1990 to less than 10% of the world's population by the end of 2015. This dramatic fall in poverty has been due to a turn towards the protection of private property, freedom of contract, and most importantly, the establishment of the rule of law during this same period, particularly in areas that abandoned central economic planning, such as China, India, and Central and Eastern Europe. This more recent phenomenon of modern economic growth is a part of a progressive transition in societies that began first in Western Europe, from one in which wealth is accumulated through political transfers of privilege to a politically connected few, to one in which wealth is created through voluntary market exchange and innovation among many anonymous strangers. This social and economic transition is fundamentally based on an *institutional transition* towards the emergence and establishment of the rule of law, or as Maine put it, “*from Status to Contract*.”

However, the importance of the rule of law is not simply due to economic development in terms of increasing growth rates (Ručinská et al. 2016). Wealth creation produced by productive entrepreneurship within the rule of law is necessary, but not sufficient for explaining human progress. Boettke and Subrick (2003) find that the rule of law also positively affects human capabilities, which refers to ability of individuals to lead the sort of lives that they value. That is, a variety of *noneconomic* fundamental aspects of the human existence, including life expectancy, child mortality, literacy rates, and immunization, are positively related with the protection the rule of law. Therefore, the rule of law is good for

development, and development is not just good for one's stomach but also one's mind and soul.

This entry explores the connection between the rule of law and economic performance. First, we analyze the role of interjurisdictional competition, and how the rule of law emerged as a by-product of this competitive process, initially in Western Europe. Second, we discuss the role of intra-jurisdictional competition between interest groups, which reinforced the emergence of the rule of law within states. Finally, we discuss the mechanism by which the rule of law successfully or unsuccessfully became established in Western offshoots, particularly in Africa and the Americas, affecting the long-term economic performance of these areas.

The Emergence of the Rule of Law Via Interjurisdictional Competition

The degree to which the rule of law will lead to economic development depends upon whether or not the discretionary hands of a ruler are tied from altering property rights arbitrarily. Otherwise, entrepreneurship will be directed into unproductive activities. According to North and Weingast (1989: 804), "A ruler can establish such commitment in two ways. One is by setting a precedent of 'responsible behavior,' appearing to be committed to a set of rules that he or she will consistently enforce. The second is by being constrained to obey a set of rules that do not permit leeway for violating commitments." Beginning in a world in which governments have not established a credible commitment to predate its subjects, the question, then, is how did the rule of the law first emerge in the West?

Weingast (1997: 245) attempts to explain "the remarkable variation among states in the rule of law." In his framework, the rule of law is understood as "a set of stable political rules and rights applied to all citizens," one among many possible equilibria in a political-economic game between the government and the different subsets of the citizenry. Governments are often tempted to act arbitrarily to their own advantage. The citizens as a collective have an interest in constraining the

arbitrary actions of the government. But any subset of the population will sometimes gain something from these violations of the rule of law.

The logic of the classic prisoners' dilemma game applies. As evidence of this, historically, most societies have been trapped in a subpar equilibrium. Members of society disregard (and sometimes encourage) the violation of the rule of law whenever it benefits them. Escaping the subpar equilibrium requires coordination among citizens. Oftentimes, this can be so costly to being unfeasible. To make the rule of law a self-enforcing constraint on governmental interference with society, the interests and beliefs of large sections of the citizenry must be aligned, at least to some degree. Thus, societies with high degrees of fractionalization (ethnic, cultural, political) are less likely to coordinate than more homogeneous ones (Weingast 1997).

These obstacles notwithstanding, coordination is possible. The rule of law, as it emerged first in Western Europe, was an emergent phenomenon of human action, though not of human design. Given the politically fragmented nature of Western Europe, violent international competition between states required European political leaders to finance the maintenance of strong military forces against the threat of conflict. In order to finance military expenditures, such political leaders were incentivized to expand their tax revenue base in a wealth-maximizing manner, the unintended result of which was for the political elite of each state to attract merchants, bankers, and technological innovators by securing property rights in their resources. The effect of this institutional change was to encourage the development of capital markets capable of mobilizing large concentrations of wealth from which to tax and borrow. Moreover, in order for the political elite to have tapped this economic potential, this required not only security from arbitrary expropriation and confiscation but also toleration of technological experimentation and new ideas that would yield savings and investment. These institutional changes facilitated the expansion of technological innovation and productive specialization under the division of labor. As an unintended consequence of such action, feudalistic privileges

were gradually eroded and economic and political liberty was reinforced until a critical threshold was met, leading to an explosion of economic growth in the early nineteenth century (Rosenberg and Birdzell 1986; Cowen 1990).

The Emergence of the Rule of Law Via Intrajurisdictional Competition

The rule of law first emerged not only via interjurisdictional competition between competing states but also through intrajurisdictional competition between competing interest groups. North et al. (2009) provide a generalized version of this framework, with a stronger focus on the role of the elites. The fundamental puzzle driving their investigation is why the elites would ever extend their rights and liberties to the public at large. Historically, the natural state of human societies has been one dominated by relatively small groups or coalitions of a few large interest groups. These interest groups have the ability of using violence to appropriate wealth from the rest of the population. But as conflict is potentially very costly even for the stronger parties, the interest groups (and the subjects as well) face a strong incentive to institutionalize wealth extraction to minimize the expected costs from conflict. The resulting coalition of interests must therefore generate enough rents for each of its members to prevent defection. Legal monopolies and other special privileges are the way in which these rents are generated (Olson 1982). The public at large suffers from the resulting welfare losses, but it is actually better off than the more likely alternative of a civil war.

To operate effectively, the rent-seeking coalition needs a set of rules to govern the interactions among its members. The resulting norms are the seeds of the modern rule of law. Thus, the government will enforce property rights and contracts by providing institutions for the resolution of disputes between coalition members. Once these institutions have been established, society is on the brink of what the authors call “open access order,” or a rule of law regime. In a pacified society, where all gains from trade within the coalition have been exhausted, there is a potential

benefit from extending these institutions to a broader subset of the population. The coalition can credibly commit not to reverse the process by decentralizing political power (Weingast 1995) or extending political enfranchisement (Acemoglu and Johnson 2005).

The classic example is post-Glorious Revolution England (North and Weingast 1989; Acemoglu and Robinson 2012). The seeds for the self-enforcement of the English constitution after the Glorious Revolution can be traced back to the reissue of the Magna Carta in 1225. Leeson and Suarez (2016: 43) emphasize how the eventual self-enforcement of the Magna Carta required three conditions: (1) common knowledge among groups of citizens about when the ruler has violated the constitution; (2) rendering it in the interest of each group of citizens to rebel in order to enforce constitutional constraints on the ruler; and (3) creating a shared expectation among those groups that the others will rebel if the ruler violates the constitution, which in turn makes it rational for each such group to itself rebel in this event. These conditions also apply to explain the success of the Glorious Revolution in England.

Following the short interlude of Cromwell’s republican regime, the English parliament had restored the Stuart dynasty to lead the country. Within the next few years, the Crown took a series of actions to undermine the interests of the reformist and constitutionalist Whig party. Finding these actions to their own advantage, the Tories (the members of the conservative and monarchist party) aligned themselves with the Crown. This lasted until the 1680s, when the Stuarts started to take similar actions against the Tories. In 1688, the two parties coordinated their efforts, dethroned James II, and establish the Prince of Orange as the new monarch under a new constitution agreed upon by both parties. The Glorious Revolution resulted in the establishment of the rule of law and had other positive economic results. By establishing a permanent role for Parliament in the management of the government, it directly checked the discretion of the Crown to call and disband Parliament unilaterally. Moreover, parliamentary veto over expenditures, the right to monitor the expenditure of funds, and

the established supremacy of common law courts assured the protection of private property rights from expropriation and discretion.

The Colonial Origins of the Rule of Law

In the previous sections, we discussed the endogenous formation of the rule of law through competition between states and competition between interest groups within states. However, the literature on the colonial origins of economic performance illustrate where and how the rule of law can be exogenously established. The empirical research on the relationship between rule of law and economic performance falls under the umbrella of development economics. Building on the theoretical insights of Smith (1776), Hayek (1960), North (1990), and others, by the early 2000s economists started paying attention to the role of institutions as determinants of economic development. This institutional paradigm emerged in response to the (at the time) influential view that geography was a major factor in determining a country long-run economic prospects (Diamond 1997; Sachs and Warner 1997; Gallup et al. 1999). The first major contribution to this literature is a famous paper by Acemoglu, Johnson, and Robinson on the “colonial origins” of economic development (Acemoglu et al. 2001). Here, the authors attempt to disentangle and identify the causal effect of geographical and institutional factors on long-run economic growth. To do so, they take advantage of a natural experiment of history: the European colonization of Africa and the Americas.

According to their story, the mortality rate of early settlers influenced the adoption of institutions by the colonial governments. Where settlers’ mortality was low, colonial governments encouraged the immigration of individuals from the homeland. To move to the colonies, European settlers demanded the adoption of a set of institutional measures associated with the rule of law (the protection of basic human rights and private property and some form of political representation). In other regions, higher settlers’ mortality prevented similar migratory patterns. Dealing

with a mostly indigenous population, colonial governments adopted political and economic institutions aimed at the extraction of resources (including indigenous labor’s services).

Relying on the sluggish nature of institutional change, and using settler’s mortality as an exogenous determinant of institutional diversity, the authors find the quality of institutions adopted by colonial governments is a strong predictor of today’s economic performance. Furthermore, the authors find that, controlling for institutional quality, geographical factors usually assumed to play a causal role in the dynamics of development such as distance from the equator, have no *independent* effect on long-run economic growth. According to Acemoglu et al. (2001), geography affects economic performance only through their effect on institutions.

In a follow-up to their original article, the same authors adopt a different empirical strategy to reach similar conclusions (Acemoglu et al. 2002). Here, urbanization and population density at the arrival of the Europeans take the place of settlers’ mortality rate as instruments for institutional quality. A higher population density at time of discovery provided colonial governments with a pool of disposable and cheap labor to be exploited, while less inhabited areas required the influx of large numbers of workers from the homeland. In the former case, the colonists adopted the indigenous extractive institutions where they were already in place and made-up their own otherwise. In the latter case, they imported private property and constitutional government. This exogenously determined institutional diversity, the authors find, accounts for the puzzling case of the “reversal of fortune” of the last five hundred years: those extra-European regions that were the richest (poorest) before colonization are today among the richest (poorest) in the world. Glaeser et al. (2004) and La Porta et al. (2008) provide an alternative (but similarly influential) empirical approach to the same question. In their strategy, the initial institutional variation across countries is due not to the decision of formal political institutions, but the prevalent legal regime in the colonists’ home country. They separate between (English) common law

on the one hand and a variety of “families” of civil law (French, German, Scandinavian, and Socialist). The authors find that, in general, common law countries outperform civil law ones on most measures of institutional quality that are strongly positively correlated with economic performance, including constraints over governmental arbitrary powers, quality of public officials, property right protection, and so forth. All these findings are consistent with the traditional understanding of the beneficial nature of the rule of law: the closer a country’s institutions to the ideal of the rule of law, the more effective these institutions and the more dynamic and productive the economy.

Conclusion

Private property rights and entrepreneurship are necessary, though not sufficient for economic development. Given the scarcity of resources, property rights and entrepreneurship are ubiquitous, but their manifestation is ultimately contingent on the presence of the rule of law. Property rights over resources can be acquired through productive entrepreneurship via market exchange (i.e. profit-seeking) or through unproductive entrepreneurship via political exchange (i.e. rent-seeking). Fundamentally, the rule of law is *the* institutional filter that restricts the exchange of private property and productive entrepreneurship to the coordinating invisible hand of the market process, rather than being guided by the discretionary visible hand of the political process (Boettke and Candela 2014).

Recognizing the link between the rule of law and economic performance has important implications not only for economic theory but also for economic policy as well. As evidenced by the American financial crisis of 2008, the European sovereign debt crisis, and the recent Brexit vote of June 2016, discretionary monetary policy, fiscal policy, public administration, and labor market policy has lead increasingly to a movement away from societies based on contractual exchange to societies based on the status of expert rule, which privileges nondemocratic, expert administration of independent regulatory agencies that violate

the rule of law. If this trend continues, the overall effect will not only lower standards of living but also erode civil liberties and increase the fractionalization of societies, as a result of legislation privileging certain groups of people at the expense of another. As we have tried to argue in this entry, political officials cannot violate the rule of law for the purpose of expediency without simultaneously stifling the principles upon which the spontaneous creative powers of a free civilization are based.

Schmoller, Gustav Von

Daniel Nientiedt

Walter Eucken Institute, Freiburg, Germany

Abstract

Gustav von Schmoller (1838–1917) was a German economist. As the leader of the younger historical school, he was a very influential academic in Imperial Germany. This entry describes Schmoller's life and career, his particular approach to economics, as well as two important methodological disputes that he participated in.

Life and Academic Career

Gustav von Schmoller was born on 24 June 1838 in Heilbronn. Starting in 1857, he studied *Kameralwissenschaft* (akin to modern public finance) at the University of Tübingen. He graduated in 1860. As part of his civil service clerkship, Schmoller worked at the Württemberg Statistical Office, where he evaluated the industrial craft census (*Gewerbebezahlung*) of 1861. This led to a publication in the *Württembergische Jahrbücher*, and, eventually, an offer of a professorship at the University of Halle.

Schmoller began teaching at Halle in 1864. His research there focused on the history of German small scale industry, resulting in the

1870 monograph *Geschichte der deutschen Kleingewerbe im 19. Jahrhundert*. In 1872, Schmoller became professor at the University of Strasbourg where he produced a book on the cloth and the weaver guilds of the city (*Die Straßburger Tucher- und Weberzunft*, published in 1879). As we shall see, the narrow focus of these earlier works is a clear indicator of Schmoller's approach to economics in general.

In 1882, Schmoller assumed the chair of political economy at the University of Berlin. During the three decades that followed, he dominated German economics, serving as editor of one of the main journals (later renamed *Schmollers Jahrbuch* in his honor) and wielding considerable influence on academic appointments. He also became a member of the Prussian parliament. Schmoller's magnum opus *Grundriss der allgemeinen Volkswirtschaftslehre* was published in two volumes in 1900 and 1904. He passed away on 27 June 1917 in Bad Harzburg.

For biographical details on Schmoller see Balabkins (1988) or Winkel (1989). Regrettably, very few of his works have been translated into English; on this aspect, see Senn (1993).

The Schmoller Program

A good description of Schmoller's research program has been provided by Joseph Schumpeter (1926). He notes that what is assumed as given in theoretical economics becomes the subject of

investigation in the *Schmollerprogramm*. These facts include “the particulars of a nation’s economic environment, the endowment with natural resources, capital and machinery, the position in international trade, the social structure, size, composition and distribution of the social product, and the economic and political constitution” (Schumpeter, quoted in Backhaus 1993, pp. 4–5).

According to Schmoller, it is the task of the researcher to collect this information, make it accessible and analyze the technical relationship of the different variables. In practice, this meant the accumulation of large amounts of historical material on very specific topics – such as the Strasbourg guilds mentioned above – so as to understand economic phenomena in their full complexity. However, Schmoller ultimately hoped to find empirical regularities that would allow for the formulation of historical laws (Ebner 2000).

From a modern perspective, a remarkable aspect of Schmoller’s approach was his commitment to interdisciplinary research that draws from disciplines such as psychology or anthropology to enrich economic analysis (Backhaus 1993). Because of his interest in the functioning of social institutions, Schmoller has been referred to as a forerunner of the field of institutional economics (Schumpeter 1926) and the new institutional economics (Richter 1996).

Schmoller’s research program must be viewed in the context of the German historical school, a nineteenth-century movement in the fields of law and economics which was rooted in German idealism. The school maintained that economic events are particular to a certain historical or cultural context. What distinguished Schmoller, the leader of the “younger” historical school, from his predecessors, was his intention to combine scientific research with the pursuit of social policies (Pribram 1983). Indeed, Schmoller has been described as being primarily motivated by the desire to address contemporary social policy issues, such as the plight of workers during industrialization (Grimmer-Solem 2003). Characteristically, the German Economic Association, which he helped to establish in 1872, was – and still is – named *Verein für Socialpolitik* (Social Policy Association). For more information on

Schmoller’s views on social reform and the role of the state see Backhaus (1997).

Two Battles over Methods

Today, Schmoller is possibly best remembered for his role in two methodological disputes or “battles over methods” (derived from the German *Methodenstreit*) that have had a significant impact on the development of the social sciences. It should be noted that, in both cases, Schmoller supported the position that was eventually abandoned by the economics profession.

The original *Methodenstreit* was fought between Schmoller and the Austrian Carl Menger. In 1883, Menger published a book defending the use of abstract theory and deductive reasoning in economics. With respect to the necessity of the theoretical method, he observed “that *history*, to be sure, has the task of making us understand *all* sides of *certain* phenomena, but that exact *theories* have the task of making us understand only *certain* sides of *all* phenomena” (Menger, quoted in Caldwell 2004, p. 68). While Schmoller could have agreed with the importance of theory, Menger also emphasized that theory cannot be deduced from empirical observations, thus attacking the very foundations of the inductive-historical method. Schmoller published a skeptical review of the book, which led to an angry exchange of letters and papers that lasted for over a decade. For more details see Hodgson (2001).

The second dispute, between Max Weber and several social reform-oriented members of the *Verein für Socialpolitik*, including Schmoller, took place in the years leading up to World War I. Since it was concerned with the problem of value-freedom in the social sciences, it has become known as the *Werturteilsstreit* (value judgment dispute). Weber (1949) famously argued that scientific assessment of facts should be strictly distinguished from value judgments. Schmoller, on the other hand, maintained that some value judgments are more objective than others because large groups of people share certain moral ideas. For a discussion of Schmoller’s contribution to this debate see Hagemann (2001).

Impact and Legacy

Schmoller's influence during his lifetime stands in marked contrast to later assessments of his work. When discussing Schmoller's legacy some 25 years ago, Jürgen Backhaus noted that he is "widely ignored by professional economists today" and that "the few who know about him generally consider his work irrelevant" (Backhaus 1993, p. 3). Still, a quarter century later, there is arguably a renewed interest in the way that Schmoller thought about economics. Following the financial crisis and recession, there exists a demand for an approach that considers economic questions within their real-world cultural, social, and political contexts. As emphasized by the current editors of *Schmollers Jahrbuch*, such an approach – sometimes referred to as "contextual economics" – is consistent with Schmoller's understanding of economics as a "practical discipline where a turn toward the object (confronting actual economic conditions), the acting agent (and her or his perceptions), as well as problems (the social question) were what really mattered" (Goldschmidt et al. 2016, p. 5).

Definition

Every year, millions of peer-reviewed scientific papers are written, submitted to, and evaluated

by the referees of the thousands of scholarly journals through which researchers and academics over the world try to publish to promote their ideas and at the same time enhance their reputations. In all disciplines, albeit with partly different rules, scholars take part in this collective game called “scholarly publishing” which, through a historical process of progressive refinement and consolidation, has become central to modern scientific practice.

Yet, in recent decades, technological change seems to be challenging the consolidated organization of scholarly communication, through the innovation of open access (OA) publishing. OA on the one hand promises to make knowledge universally accessible but on the other hand alters the equilibrium on which the traditional system of scientific journals was based. In fact, the change is not merely a technological substitution but rather involves the complex economic and social organization that governs the world of scholarly publishing and especially that of research. Various inertias constrain the behavior of the different stakeholders in research, with important – and also potentially distortive – effects on the adoption of new technology.

Scholarly Research and Publishing: Main Characteristics and Organizational Structure

The principal function of scientific research is to produce and circulate knowledge advances, and the scientific community has spontaneously organized itself – in more or less complex ways – to carry out this task (Origgi and Ramello 2015). To pursue this aim and govern the erratic dynamics of science which “[...] is not a system of certain, or established, statements; nor is it a system which steadily advances towards a state of finality” (Popper 1959, p. 278), and instead progresses through a widespread dialectical process of validation and critical selection of results, there spontaneously emerged a “republic of science,” i.e., a specific organizational structure based upon its own social norms and institutions (Polanyi 1967).

Within that context, certain instruments have become essential for the functioning of the community. Among these, scholarly journals can be regarded as the cornerstone of the modern international scientific system, since they effectively perform several distinct, though interrelated, functions vital to the world of research. In particular, in addition to disseminating scientific advances, publications have a central role in the selection and validation of results, as well as in producing incentives for researchers (Clemens et al. 1995; Migheli and Ramello 2018). It is no coincidence that the imperative which today governs the day-to-day work of scientists across the world is “publish or perish,” against which backdrop scholarly journals play a predominant role. The peer review system, citations, and rankings have for some decades formed the framework of research activity and furnished (though subject to much criticism) the benchmark for measuring scholars’ productivity and determining their remunerations (Leahey 2007; Davis 2009).

Today, in many countries, the number and placement of published papers determine researchers’ prospects for career, tenure, and promotion, as well as their economic rewards – whether direct (e.g., higher salary, research prizes, etc.) or indirect (e.g., fame and reputation which can be monetized in alternative markets such as consulting) – and their ability to secure funds for future work from the public system (through research assessments) or from private sponsors (Origgi and Ramello 2015; Migheli and Ramello 2018).

In studying the dynamics of citations, Merton (1988, p. 620) likens them to a coinage system which makes it possible to capitalize “pellets of peer recognition that aggregate into reputational wealth” for individual scholars. Taking up this metaphor, we can say that, in the modern scientific system, the stock of reputational wealth accumulated by researchers consists of their publications, just as the financial wealth of individuals consists of their investment portfolios. Continuing the analogy, the journals in which articles are published can be likened to the issuers of financial instruments, characterized by a certain level of quality and reputational yield. Yet, whereas

financial markets have an inverse quality/performance ratio, that of academic publication is direct. In other words, whereas financial markets expect low-quality issuers (products with low ratings) to provide higher yields than high-quality issuers, in scientific publishing, high-end journals provide authors with greater prestige and a higher remuneration.

On the whole, peer-reviewed journals provide an immediate, even if imperfect, signal that can be converted into reputation, prestige, and all the attendant benefits for individual researchers. The metrics of impact factor and journal rankings depend more or less directly on the total number of citations, irrespective of the relevance of each individual contribution. This means there is a standard “yield” for papers published in a given journal, thus making citations fundamental for defining researchers’ value in the academic job market.

Naturally, like any financial instrument, journals are subject to fluctuations in value, and a careful selection on the part of scholars generally tends to favor “safe investments,” by virtue of their history or because they are regarded as such by the social norms which govern scientific communities (Clemens et al. 1995; Park and Qin 2007; Migheli and Ramello 2014). This gives rise to a self-perpetuating rigidity and inertia in the prestige of journals, and so also in the publication choices of researchers, which can only be broken by some external intervention, random shock, or purpose-designed policy (i.e., a form of “financial policy”) that has the effect of altering perceptions and hence the decisions of individuals (Migheli and Ramello 2013).

In the case of scientific journals, this outcome can be achieved in two ways: indirectly, by using a sort of “brand extension” to transfer to a new journal prestige established elsewhere (e.g., endorsements by scientific societies, links with other journals or prestigious universities) or, directly, by altering the existing system of incentives (Migheli and Ramello 2018). In the latter case, for example, an institution that funds research could impose ex ante constraints relating to publication choice, or a research department could create a reward system, either

direct (a bonus) or indirect (higher consideration of certain publications when evaluating research, moral suasion), that makes it rational to deviate from the previous conformist route of choosing well-established and “safe” journals.

A step in this direction, for example, is the widely discussed National Institutes of Health Public Access Policy, known as the “NIH mandate.” To ensure public access to research results, the NIH requires that final, accepted peer-reviewed journal manuscripts that are the product of NIH-funded research must be made freely accessible in the PubMed Central digital repository (<http://publicaccess.nih.gov/>). Among the operations of moral suasion on the part of institutions, we can cite, in chronological order, the *Faculty Advisory Council Memorandum on Journal Pricing* of Harvard University, eloquently subtitled “Major Periodical Subscriptions Cannot Be Sustained” and which calls for authors, editorial board members, and scientific associations to take specific actions in favor of OA publication (see points 2, 3, and 4 of the memorandum; <http://isites.harvard.edu/icb/icb.do?keyword=k77982&tabgroupid=icb.tabgroup143448>).

Naturally, for scholars to play the “publish or perish” game, a necessary (though not sufficient) condition is the ability to access existing knowledge, i.e., already published papers. This poses a problem because, up until very recently, the business model on which journals relied was exclusion of readers through price – known as the *subscriber-pays* model (and hereinafter also denoted Restricted Access, or RA) – as commonly practiced in markets for a wide array of goods and services. The subscriber-pays solution involves the transformation of a public good – scientific information – into a private information good, thus creating a trade-off between rationing as a way to give publishers an economic incentive and the exclusion of follow-on researchers who cannot pay the cost of access (Origgi and Ramello 2015).

Various compromises have been arrived at over time to minimize this exclusion while at the same time producing sufficient incentives. Generally, the approach taken has been to make journals

a club good, that is to say a sort of local public good for a vast population of individuals (Cornes and Sandler 1996). For example, scientific associations have often included their own journals in their membership fees, thereby making them accessible to all members. On their part, libraries have likewise played a fundamental part in making journals accessible to users located in the geographical vicinity of the library. This practice in effect solved the financing problem through an unprecedented form of price discrimination, which imposed on the subject best able to bear the financial burdens – i.e., the libraries – the high costs of purchasing journals, while providing access at a much lower price (or sometimes for free) to the individual users of the library (Liebowitz 1986). The system worked so well that, from the point of view of academics, the online accessibility of paid-for journals was often perceived as a form of OA.

However, in recent times the above mechanism started to falter. Commercial publishers, also thanks to a process of concentration, increased their market share. This, combined with an essentially rigid demand, led to steep increases in price, further favored by the bundling practices made possible by selling large catalogues of journals in electronic format, known as the Big Deal (McCabe 2002). Compounding this was an unconnected – but not for this less important – contraction in the budgets of universities, and consequently of libraries, which began to force some dramatic choices. Initially, the rigid demand for journals worked in their favor, prompting libraries to assign journals a larger share of their budgets, at the expense, for example, of books and monographs. However, a more significant consequence, for the purposes of this analysis, is that eventually libraries became less and less able to maintain their existing catalogues, culminating in what is now referred to as the “serials crisis” in the literature (Panitch and Michalak 2005). At first, the problem affected the smaller universities and those of less wealthy countries, but it has now come to plague even the most prestigious institutions, as testified by the aforementioned case of Harvard University.

These tensions, which made it harder to access journals, prompted a wide-ranging debate on the need to alter the status quo through policies designed to favor a shift toward an open system (Bergstrom 2001) and in some cases prompted more drastic reactions, such as the abandonment of certain journals on the part of editorial boards or scientific societies – as happened, for example, to the *European Economic Review* (Cavaleri et al. 2009) – or the boycotting of certain publishers by declining the various possible forms of collaboration.

New Trends in Scholarly Publishing

Against this backdrop, there emerged the innovation of free electronic journals, introduced around the 1990s (and only later labeled open access, or OA), which were widely regarded as the disruptive innovation that could solve the existing problems and return scientific advances to a sphere more compatible with the nature of knowledge as a public good. Many contributions have pointed out the advantages that these new publications offer compared to journals based on the *subscriber-pays* model and have urged their extensive adoption (Bergstrom 2001; Parks 2002; Willinsky 2006).

Some authors have even expressed expectations far beyond the realm of technological change, seeing in OA journals a universal remedy that can solve all the problems of scholarly communication (Harper 2009). In similar vein, a British antitrust investigation into presumed anti-competitive practices in the market of scholarly journals in science, technology, and medicine, in the words of the authority chairman Sir John Vickers, concluded that “the market, which operates world wide, has a number of features that suggest that competition may not be working effectively. *However, market forces harnessing new technology may change this without the need for intervention*” (OFT 2002; the italics are ours).

Still, even though there are ample signs of an increasing presence of OA journals and papers in the world of research, the market of traditional

RA journals continues to flourish for a number of reasons (Laakso et al. 2011; Migheli and Ramello 2014). In fact, not only does RA provide incumbents with large and growing profit margins: in many sectors, it also relegates OA journals – with some exceptions – to a subordinate role on the sidelines of scholarly communication.

Therefore, despite the OA model's disruptive potential to better disseminate scientific advances and lower production, printing, and distribution costs (Houghton et al. 2009), the scholarly communication system exhibits structural rigidities tied to the existing system of incentives, essentially stemming from social norms and prudential attitudes on the part of researchers.

Indeed, the persistence and stickiness of the social norms governing researchers' behavior with respect to publication choice can become crucial in determining the uptake of new technological opportunities and the dynamics of scholarly communication (Migheli and Ramello 2013, 2014). In other words, publication choice does not seem to be determined by any specific, immutable preference for a given technology platform but rather by the scientific community's lack of "absorptive capacity," i.e., what the innovation literature defines as the ability of players (here, scholars and research institutions) to recognize and adopt the opportunities offered by major technological breakthroughs, such as OA publishing (Cohen and Levinthal 1990; Feess and Scheufen 2016). The puzzle to unravel therefore concerns the signals produced by the existing RA system, which are not easily replicated in the OA realm without the help of some exogenous intervention or shock. Understanding the dynamics that determine preferences, and hence choices, within a given scientific community is thus an essential starting point for identifying possible drivers of change.

The Long and Winding Road of OA Publishing

The OA movement took off with the information and communication technology (ICT) revolution, which greatly reduced the investment in cost and time required to produce a journal, while also offering unprecedented ease of distribution. Naturally, the new technology is available to all

journals, and it can only bring about change if used in a certain way: commercial publishers see the ICT revolution as merely a new tool for pursuing price discrimination strategies by creating electronic catalogues; OA publishers instead emphasize its ability to offer high-quality peer-reviewed content in digital format without any access restrictions (McCabe 2002; Willinsky 2006).

The OA philosophy is thus a product of the encounter between technological opportunity and a new business model: it is the two innovations together – technological and economic – that enabled a Copernican Revolution which overturned the traditional model of scholarly communication. Scientific knowledge, hitherto "boxed in" by the practical necessities of paper journals – which, through reification of the physical medium, assimilated knowledge to a traditional consumer good – could once again become a public good thanks to marginal costs of duplication and dissemination that are equal to zero.

However, the OA approach also brings back to the fore a characteristic problem for information, that of provision of a public good. Whereas the RA model resolved this in the market, through payment of a subscription fee, in the OA realm, it is necessary to find other solutions that lie outside the market or which are linked to complementary markets.

A variety of models have been proposed: the first is *patronage*, in part also familiar to RA journals, whereby an institution takes charge, entirely or partially, of the costs of the journal. Another model to rely on is *advertising*: as already happens in other media sectors (e.g., in free-to-air television), the publisher operates in a two-sided market that on one side meets the scientific community's demand for content and on the other side sells the audience's attention to firms (Anderson and Gabszewicz 2006). Finally, the model most commonly adopted to date has been to overturn the financial burden, transferring it to the party that most directly and immediately benefits, that is to say, the author. This introduces a novel conception of the market, termed the *author-pays model*, whereby researchers pay for the service of having their results selected and

circulated, rather than for accessing the work of others. Such a model has the advantage that, for an equal amount of expenditure, it eliminates the exclusion through price of part of the audience and lets research results remain a public good. It is therefore a cost-effective solution (Bergstrom and Bergstrom 2004; Houghton et al. 2009). That being said, the *author-pays model* is not immune from criticism because it raises the direct costs of research and excludes those who cannot pay the publication fee (Gass 2005).

While the different alternative financing models are extensively discussed elsewhere (Houghton et al. 2009), we focus here on the unequivocal fact of OA publishing's continued expansion (Laakso et al. 2011). The Directory of Open Archive Journals (DOAJ) is an ever-growing list of the principal OA journals that follow the so-called golden road, meaning they offer all their content free of charge (Harnad et al. 2004). Added to these are the many RA journals that occasionally offer – often on payment by the author – an OA option for individual papers (this is the so-called hybrid form; Björk 2012). Carroll (2011) however notes that hybrid forms are not truly OA since they do not clearly define the rights of readers, such as whether reuse, free circulation, and so forth are permitted. Finally, we can add a large catalogue of freely accessible “working papers,” i.e., preliminary versions of papers published in RA journals, a practice known as the “green road” (Harnad et al. 2004).

These last two forms show how OA has come to increasingly permeate the day-to-day scientific work of researchers, as well as the interest OA has elicited – through the hybrid form – even among traditional journals with a strong for-profit orientation. It is thus all the more intriguing to try find out why gold OA journals have nonetheless had difficulty becoming established in certain fields, in apparent contradiction with the widespread favor they enjoy in the scientific field.

The geographical distribution of OA journals is quite broad (the figures, always in-progress, are provided by the DOAJ listing) published in more than 100 different countries. Of these, around 15% are published in the USA, and if we consider all Anglo-Saxon countries together, they

account for the lion's share, with over 2000 titles. Europe and Latin America also have substantial numbers of OA titles, whereas in the rest of the world, distribution is more fragmented. The “economics” category amounts to a relatively small subset of the DOAJ universe, but this number increases substantially if we also include the titles under “management and business.” Tradition is well established, and the oldest OA journal, *Economics Bulletin*, was established in 2000 (operational from 2001) by John Conley and Myrna Wooders and is archived by the University of Illinois at Urbana-Champaign (Conley and Wooders 2009). Interestingly, the American Economic Association has for the past few years offered all the content of the *Journal of Economics Perspectives* on an OA basis, but in place of this label, the website prefers: “with the compliments of the American Economic Association.”

Publication Choice and the Open Access Paradox

The above description gives us a general idea of the trends followed in recent years. However, they tell us nothing about the reasons for this dynamic nor anything specifically about the role of demand in determining the establishment of OA in scientific publishing.

Behavioral analysis is a useful instrument that can help us penetrate the social black box, understand the trajectory of OA journals, and formulate policy guidelines for promoting the adoption of OA within the scientific community if this – as would appear from the cited cases – is a goal research institutions wish to pursue. However there has been research addressing this question in the fields of medicine, life sciences, physics, economics, and chemistry.

Over the past two decades, there have been a number studies investigating the attitude of scholars to scientific publications in general and to free access publications in particular. However, these investigations were conducted at very different times, in very different contexts, and following widely disparate methodologies. Xia (2010) and Davis and Walters (2011) systematize

a set of empirical studies based on interviews with small samples, and surveys instead conducted on larger populations, generally focused on Europe, North America, and Australia, thus providing a Western-oriented perspective. The samples investigated are fairly diverse and present structural limitations (opportunately noted by Xia 2010; Davies and Walters 2011) but still allow us to detect broad correlations and extract insights for further research. The most noticeable pattern to emerge is scholars' attentiveness to the quality and perceived reputation of journals, confirming the idea that scientific papers are effectively regarded as fundamental assets in the research job market and that community consensus is effectively the pervasive reference framework in which choices are made (Migheli and Ramello 2014).

From the academic career perspective, OA journals should be technologically neutral, since they can just as easily as RA journals produce results aligned with the incentive system of the academic job market. Yet certain peripheral features of this new form of scholarly publishing may elicit diffidence. For example, there tends to be an aversion (though this has been abating over the years) to payment of an author's fee, motivated on one side by the fear that this will increase scholars' direct costs of doing research and on the other by concerns about a possible quality trade-off between maximizing journals' profits and the rigor of the peer review process (Davis and Walters 2011; Migheli and Ramello 2014).

As discussed previously, two important factors driving publication choice are the expected number of citations, both individually and for the journal, and the visibility of published papers (Migheli and Ramello 2018). Both of these appear to be correlated with the number of downloads, which is today the most common method of consuming both OA and RA journals. Accordingly, some studies have sought to measure these values. There has even been a sort of natural experiment conducted by Oxford University Press, which converted its flagship journal on molecular biology (*Nucleic Acid Research*) from RA to OA. For a given journal reputation, this operation first of all yielded increased profits for the publisher but

also an increase in downloads (though with some uncertainty as to the numbers, since these were partly due to search engines). Still, even the estimated increase without counting search engines, of +7–8%, is noteworthy if we consider that this was an already established journal, which means the entire rise can be ascribed to the effect of OA in making content more visible. We do not as yet have any clear indications from this experiment on the effect upon citations (Bird 2008), and in any case the journal in question might be expected to have a reputation and inertia deriving from its previous RA status. Generally, if the equation “more downloads=larger readership=increased citations” was to prove true, it ought to give OA journals a formidable lever for building their ascent while allowing individuals to comfortably base their publication choices on a self-enforcing prophecy.

This suggests the hypothesis that, in the absence of clear indicators, the choice of preferring traditional journals (generally RA) is a behavior aimed at minimizing risk under the currently existing social norms. Such a hypothesis could provide a reasonable explanation for an intriguing ambivalence observed in various studies, which might be termed the “open access paradox”: scholars generally express strong support for OA and use it extensively, also via the green road, but this enthusiasm is not later transferred to their publication choices (Park and Qin 2007; Hubbard et al. 2011; Migheli and Ramello 2014). Although the stated system of preferences should theoretically influence individual actions, the expressed desirability of OA journals is contradicted by researchers' reluctance to submit their papers to those journals.

This seeming contradiction between assertions of general principle and individual behavior poses the interesting puzzle of a possible divergence between individuals' incentives and what they regard as the collective interest. The solution to the paradox probably involves rational choice prevailing over the emotional sphere, suggesting that policies aimed at changing the status quo must necessarily follow the route of altering the economic incentives. In other words, we can reasonably expect OA journals to gain market

share and become substitutes for other titles, provided that a self-enforcing prophecy is triggered which causes an ex post outcome in the reference scientific community that is compatible with the incentives that existed ex ante.

It is therefore a question of identifying the factors that determine how individual researchers choose and evaluate journals. These include the researcher's position in the academic hierarchy, gender (because of the discrimination that women often suffer, also in academia; Leahey 2007) and working context (including the geographical location), the expected impact of OA journals in yielding visibility and reputational capital, and so forth (Migheli and Ramello 2013, 2014).

Securities Class Action

Milan, Italy

Definition

Securities class actions (SCAs) are lawsuits brought before a court on behalf of a group of investors, whose rights have allegedly been violated by the company in which they have a stake. Usually, allegations concern the fact that the company and some of its officers violated federal or state securities laws. In this article, we overview the procedural characteristics of SCAs in the USA and other countries that have established this type of legal remedy, discussing their role as compensation, deterrence, market regulation, and corporate governance tools.

Introduction

This article overviews the main features of securities class actions (SCAs, hereafter), both in the USA and in other countries, discussing their role as compensation, deterrence, market

regulation, and corporate governance tools. Relying on empirical contributions that investigated the relationship between the event of an SCA and target companies' behavior, this contribution supports the view according to which SCAs seem to be a weak tool in terms of investors' compensation and deterrence. Rather, their substantial impact on the performance of a company suggests SCAs have an important role as market discipline tools. Consequently, several scholars are increasingly convinced that SCAs are to be classified as corporate governance instruments.

Securities Class Action: An Overview

USA is the ultimate country for SCA. On the other hand, other countries have similar procedures. In the subsections below, we describe SCA in the USA since it can be considered as a benchmark and then we briefly discuss procedures in other countries.

US Securities Class Action

An SCA is a lawsuit brought pursuant to Federal Rule of Civil Procedure 23 on behalf of a group of investors who purchased the securities of a specific company (*target company*) during a given period of time (*class period*). Usually, allegations concern the fact that the company *and/or* some of its officers violated federal or state securities laws. The main federal laws that are involved in SCAs are the Securities Act of 1933 and the Securities Exchange Act of 1934. In addition, the so-called state *blue sky laws* – aimed at protecting individual investors – may be alleged to be violated in SCA cases.

An SCA can be considered as a specific type of class action (CA, hereafter). With respect to many issues, considerations provided by Ramello (2014) extend to SCAs. In fact, the suit is filed as a CA because class members are so many that a joinder of all plaintiffs is unattainable.

As for any kind of CA, proceeding as a class must be superior to other available methods for a fair and efficient adjudication whereas the prosecution of separate individual actions could lead to inconsistent adjudications. According to Coffee (2006), SCAs represent the largest category of

CAs, absorbing relevant public resources of the judiciary subsidized by taxpayers.

On the other hand, SCAs are characterized by relevant specificities. One peculiarity is that, besides the usual rules governing CAs, SCAs are regulated according to more stringent requirements. In particular, after the Private Securities Law Reform Act (PSLRA) of 1995 and the Securities Litigation Uniform Standards Act (SLUSA) of 1998, class certification requires strict compliance with legal provisions that are not applied in the case of other types of CAs. The PSLRA was explicitly designed to limit frivolous securities lawsuits. Very briefly, under the PSLRA, plaintiffs need relevant proof of fraud before they can initiate an SCA. After filing, judges decide the most adequate lead plaintiff and a more active monitoring role of the court is prescribed; stringent discovery rules apply and full disclosure to investors of proposed settlements – including the amount of attorneys' fees – is mandated; bonus payments to favored plaintiffs are banned. The SLUSA was mainly aimed at curtailing the plaintiffs' practice of filing securities cases in state courts to avoid the proscriptions of the PSLRA. The SLUSA actually posed all the SCAs under both the jurisdiction and the strict surveillance of federal courts.

Beyond the procedural specificities that distinguish SCA from other types of CA, intrinsic differences should be carefully discussed to understand the everlasting debate about merits and limitations of SCAs.

As well presented by Coffee (2006), substantial differences exist between SCAs and all the other forms of both private litigation, including CAs, and public prosecution for legal violations. Main peculiarities are related to who suffers for a company's misbehavior and who bears the costs of damage compensation.

Usually, when a corporation incurs liability (even in a CA) because of a defective product, environmental pollution, or other misbehavior, the society imposes a cost on the corporation (and indirectly on its shareholders). Typically, shareholders (and other investors who have stakes in the target company) are not themselves the primary victims of the offense. Thanks to private litigation, the liability system is

enforced and the negative externality is internalized (at least partially) by the firm.

In most part of the SCAs, some shareholders (those who traded the company's securities in the class period) decide to proceed against the target company because of an alleged legal violation committed by corporate agents (executives, directors, auditors, other insiders) resulting in a damage for the shareholders themselves. Typically, the victims and the shareholders are largely the same.

The oddity of the SCA emerges quite evidently. A CA against a target company serves the rationale of the enterprise liability since it is assumed that corporate agents might engage in misconduct like production of defective products or environmental pollution to maximize profits for the company and its shareholders. Conversely, securities fraud appears to be primarily motivated by the manager's own personal interests. Except when the company is issuing new shares, inflating firm's earnings do not benefit either the company or its shareholders. Instead, executives and insiders could have self-interested reasons to inflate earnings when securities are traded on the secondary market; likewise, they have incentives to hide bad news, overstate good developments, understate risks to maximize both the value of their stock option and other equity compensations, and, eventually, improve their reputation.

In the case of securities frauds committed by corporation's executives, not only (some) shareholders are the main victims, but – in the case of an SCA – they also bear the burden of direct and indirect costs related to the legal remedy.

Obviously, SCAs should not be confused with shareholder derivative suits, which are lawsuits brought by a shareholder on behalf of a corporation against a third party. Often, the third party is an insider of the corporation, such as an executive officer or director. Shareholder derivative suits allow a shareholder to initiate a suit when the management has failed to do so.

Some Statistics: The Securities Class Action Clearinghouse Database

Scholars and practitioners who are interested in understanding the reality of SCAs can take

advantage of an invaluable asset: the comprehensive and compelling website of the Securities Class Action Clearinghouse (SCAC). The SCAC Database tracks all the SCAs filed in Federal Courts after the PSLRA. Information about plaintiffs, defendants, allegations, lawyers, court districts, judges, and settlement details involved in each case are summarized and easily available.

According to the database, from 1996 to 2016, 4,347 SCAs were filed (see Fig. 1). The impressive peak of 2001 seems related to the crash of the *dot com bubble*, given that about 58% of total filings have been filed against companies in the

ICT sector. Another specificity is observed in correspondence of the *subprime mortgage crisis*: in 2008, around 51% of total filings (46% in 2009) were against companies in the financial sector. By comparing market capitalization/GDP with the trend of SCAs, the latter seems to be somehow countercyclical.

In detail, 2,159 cases (49.7% of total filings) have been settled, for a total amount of all settlements of more than 89 billion dollars; 1,685 cases have been dismissed (38.8%), while 503 filings are still ongoing (11.6%). The largest settlement (\$7,227,390,000) has been paid by Enron Corporation in 2008 after ruling summary judgment but before trial verdict. Fees and expenses approved by the court represented 9.5% of the total settlement.

The most frequently sued sector is technology, recording 27% of total filings, services (19%), the financial sector (18%), and healthcare (15%) (see Fig. 2). The most frequently sued issuers are on the NASDAQ. The most active district court involved in SCAs is the Southern District of New York; the 2nd Circuit (New York) and the 9th (San Francisco) decide more than half of all the SCAs (31% and 23%, respectively).

This brief overview gives only a sketchy idea of the complexity and relevance – especially from a legal and economic perspective – of this kind of legal remedy. Section “[Empirical Evidence About Causes and Effects of SCAs](#)” summarizes various empirical contributions that investigated these complexities.

Other Countries

A few countries have forms of representative securities litigation working similarly to the US SCA, mainly Australia and Canada. In other countries, including England and Wales, South Korea, Germany, and the Netherlands, there are litigation tools that might be somehow assimilated to SCAs, but these significantly depart from the standards of the US Federal Rule of Civil Procedure 23. Below, only a brief selection of representative countries is considered.

Australia

In Australia, SCAs are now an established part of the legal landscape. After the first filing in 1999, several cases have been commenced. The Australian model is similar to the US SCA, but there are some relevant differences: no formal motion for class certification is required; moreover, the procedure is based on an *opt in* standard since interested claimants are required to register at the outset of the case. Like other litigation procedures in Australia, fee shifting is based on the English rule while contingent fees are prohibited (third-party litigation funding is allowed and is considered an effective substitute of the contingent fee system). See also Murphy and Cameron (2006).

Canada

SCA is available in Canada since 2004. SCAs are not regulated at the federal level, but there are province procedures that may differ and SCAs can simultaneously arise in different provinces. Until 2006, in the majority of provinces, SCA was applied only for frauds related to the primary market. However, since 2006, most provinces have amended their legislation to introduce a right of action through SCA for misrepresentations in the secondary market. The possibility to proceed for secondary market frauds significantly boosted SCA litigation. In many cases, procedural rules prescribe court approval before the action commencement, damages limitations, and the English rule for fee shifting. Sarra and Pritchard (2010) provide a detailed analysis of SCA in Canada.

England and Wales

Since 2000, England and Wales (but not Scotland) introduced civil litigation rules for the management of group litigation, including securities litigation. Unlike the US system, the English procedure is based on an *opt in* standard; the class may be represented by a lead lawyer, but also individual members of the group can have personal lawyers. The action commences with a Group Litigation Order establishing a register of the class and the involved claims; the court manages the entire procedure. The English rule of fee shifting and the unavailability of contingent fees probably limited the diffusion of SCA in England and Wales. However, as in Australia, the emergence of third-party litigation funding may favor the establishment of SCA. See also Andrews (2001).

South Korea

In 2005, SCA was introduced in South Korea. Under the local legislation, an SCA may be brought against a company for illegal acts connected with securities issued by the company including false statements, insider trading and market manipulation, and negligent audit. To proceed as a class, a minimum of 50 shareholders owning at least 0.01% of a company's equity must join as plaintiffs on behalf of the other shareholders. The CA must be certified by the court. Strict rules of representations apply: terminating the action, relinquishing a right granted under the law, or settling the case without court approval is prohibited. See Chung (2004).

Germany

The German law does not provide any specific type of representative group litigation. However, in 2005, new rules were enacted to facilitate investors' action for misstatements and omissions by issuers. In particular, according to the Capital Investor's Model Proceeding Act (Kapitalanlegermusterverfahrensgesetz, CIMPA, hereafter), amended in 2012 and valid till 2020, investors can proceed for securities claims according to a *model case*. Notably, with the CIMPA, the German legislator has provided a way to handle capital market mass proceedings

without transferring existing models of group litigation from foreign jurisdictions.

According to the procedure, both the plaintiff and defendant may enter an application for establishing a *model case* to the court. Admissible applications are publicly announced by the court in an electronic Complaint Registry. Only if at least ten applications referring to the same matter are entered in due time in the Registry, the court proceeds according to the CIMPA. While the model case proceeding is decided by the Higher Regional Court, all pending related proceedings are automatically suspended. Once decided by the Higher Regional Court, the model case is binding on all the courts dealing with that matter.

The procedure applies only to claims related to false, misleading or omitted public capital markets information, or due to breaches of the Securities Acquisition and Takeover Act. It only applies to parties who have already filed a suit and does not allow a claim to be brought in the name of an unknown group of claimants. The CIMPA, in fact, introduces a procedure which is not properly a representative lawsuit, but rather a representative case; note that the procedure is based on an *opt in* system since only claimants who choose to file an action are bounded by the model.

Litigation costs are allocated according to the English rule. Punitive damages or other kinds of noncompensatory damages are not permitted. The courts will then decide each individual proceeding itself, including the decision on individual damages. Contingency fees are available only in special circumstances. As a result, litigation funding/insurance is a common component in these suits.

The Netherlands

In 1994, the Netherlands enacted a legislation that permitted collective actions by consumer associations. In 2005, the Civil Code was amended by the Collective Settlement of Mass Damage Claims Act. Like for the US CAs, the latter ensures that class members will be bound by settlements under the Act unless they affirmatively decide to opt out. In 2007, thanks to a few cases related to incorrect financial information and financial

frauds involving the Dutch investor association VEB as plaintiff, the existing form of representative procedure extended to cases of securities litigation. As in the German case, the stockholders involved are still required to bring individual proceedings on reliance and damages issues. Under the Dutch procedure, only court-approved representative organizations (i.e., investor associations) can pursue an SCA on behalf of the investors. Furthermore, such organizations cannot seek damages in court. The court can only certify the class and decide whether to approve an out-of-court settlement between the parties. This could limit the potential of the Dutch representative action.

Finally, although this is beyond the scope of this article, consider that, today, financial markets and securities are globalized; investors, especially those of large public companies, live and trade securities in many countries. This obviously poses relevant problems of both jurisdiction and applicability of SCA procedures. The debate about these issues, and particularly about the extraterritorial effect of US SCA, has been significantly stimulated by the famous US Supreme Court's *Morrison* decision (*Morrison v. National Australia Bank*, 561 U.S. 247, 2010).

This ruling stated that the US securities laws apply only to securities transactions within the USA. In fact, the *Morrison* decision excluded “foreign-cubed” investors and “foreign-squared” cases (cases brought by domestic plaintiffs against foreign issuers and pertaining transactions on foreign exchanges) from US SCAs.

A Rationale for SCA: Compensation, Deterrence, Market Regulation, or Corporate Governance?

CA (see Miller 1979), in general, and SCA, particularly, are very controversial procedures. The main reason why the debate about the functions of securities litigation is even more vivid than in the case of other types of CA is due to the intrinsic *circularity* characterizing SCAs. As explained

above, shareholders are, at the same time, the possible beneficiaries of damage compensation inasmuch victims of company misbehavior and those who finally bear all direct and indirect consequences of an SCA.

Concerning the usual judicial functions (access to justice, compensation, and deterrence) typically ascribed to CAs, *access to justice* is the only one that is not significantly dismantled. SCAs may represent an affordable option (especially given the contingent fee arrangements) to many investors to proceed against the target company and their officers for securities frauds. As for CAs related to mass torts cases, environmental and product damages, securities frauds often affect fragmented and widespread claimants. Therefore, SCAs can be a means to improve the effective protection of collective interests and individual rights. By leading to a decision (either a court pronouncement or, usually, a settlement) against the liable injurer, SCAs offer a legal remedy in securities cases. Hence, group litigation performs the social function of granting every person to seek forms of judicial protection.

Circularity seriously jeopardizes the *compensation* function of SCAs. A first criticism is related to the fact that the net redress for class plaintiffs might be insufficient to compensate losses because of the significant fee amount to be paid to counsels and/or because of unfair settlements (Coffee 1995). A second criticism is that in SCAs the compensatory function is significantly undermined by the substantial correspondence between victims and those who finally bear direct and indirect consequences of the legal action on the target company. In fact, defendants very rarely pay for all the costs involved in an SCA by using personal resources. Typically, company's resources and D&O insurances are used to cover defense costs, damage compensation, and settlement. Even possible indirect consequences of a successful SCA, including loss of reputation and stock price drops, are borne by shareholders in the end. To the extent that an SCA imposes its costs almost exclusively on the corporation and insurers, it does not seem to benefit shareholders anyhow (Baker and Griffith 2009).

For the same reasons, the *deterrence* function of SCA seems to be substantially frustrated (Baker and Griffith 2009; Coffee 2006). Although the cost-internalization function of CA is independent of its compensatory function – and may be served even when the latter cannot – SCAs might effectively force the internalization of externalities and improve deterrence only by bringing damages back to the actual fraud perpetrators. Conversely, officers, executives, and insiders are often able to escape from direct consequences of SCA thanks to both D&O insurance policies and the economic shield provided by the target company.

According to a slightly different vision, some authors support the idea that SCAs can be an effective tool for *private enforcement of market regulation*. In SCAs, private attorneys working on behalf of investors and seeking damage compensation can promote the public interest and law enforcement (see Burch 2008; Porrini and Ramello 2011). From this perspective, it must be noted that SCAs usually result in settlement amounts that are incomparably higher than the total amount of public monetary sanctions. Moreover, Cox et al. (2003) find that overlapping between SCAs and the SEC provisions appears infrequent. This supports the idea that public regulation and private litigation through SCA might be considered as complementary means to enforce securities laws. However, once again, if wrongdoers do not pay for their misbehavior, even the private enforcement rationale becomes weaker.

A further relevant limitation of the deterrence function of SCA – and consequently of its aptitude to be a private enforcement means – is related to the fact that lawyers proceed only when expecting large recovery and then sufficiently large fee awards. For this reason, SCAs typically target only *deep-pocket* firms (large and rich corporations). This means that an SCA cannot be considered as an overall means of private enforcement since it does not deter misbehavior in small and not very well capitalized firms.

In the same fashion, some authors suggest that SCAs in the banking sector might be numbered among the *market discipline* tools. In fact, many types of abuses and negligence in the banking

sector not only affect bank safety and stability but also fall in the SEC jurisdiction and cause SCAs: if investors – or their counsels – recognize that a bank has taken on pathological risk or engaged in abuses like insufficient capitalization, negligent misappraisal of risk exposure, or leverage, they may try to control it through an SCA. When an SCA takes place in the banking sector, it acts as a tool to empower private investors to collect information, thus exerting an effective influence on targeted banks (Dalla Pellegrina and Saraceno 2011).

Even though the SCA is a very controversial procedure, a change in perspective provides it with a new rationale. Some authors, indeed, suggest that, though not traditionally included among corporate governance instruments, SCAs have relevant *corporate governance* effects.

From this perspective, some points need to be raised. First, an SCA is a critical event in the life of a corporation: filing, certification or dismissal, and settlement represent public sensitive information. Second, but in the case of palpably frivolous SCA, filing implies that allegations of negligent or fraudulent behavior possibly harmful to both investors and corporate value are ascribed to the corporation itself and its management. Third, an SCA is an unpleasant – primarily for the targeted company and its stakeholders including those who proceed against the company – result of some managerial choices (Johnson et al. 2000). Since securities litigation usually has a negative impact on stock prices and market perception of the targeted company, it is reasonable to think that SCAs is used to put pressure on reluctant boards of directors to rectify poor performance.

Because of all these reflections, not surprisingly, an SCA seems able to produce effects in terms of *corporate control*. In particular, it can be seen as a means for both shareholders and bondholders to influence the governance of a company. Plausibly, SCAs intervene when other standard corporate governance tools fail. This may happen when the interests of controlling shareholders and CEOs are aligned but in contrast with those of minority/dispersed shareholders and/or bondholders. Otherwise, shareholders would use less costly *voice* tools to realign their interests with

those of the CEO (Dalla Pellegrina and Saraceno 2016). In this respect, SCAs provide minorities with a sort of *voice*, besides the usual *exit* tools. According to Strahan (1998), SCAs are useful devices to manage residual agency problems by inducing managerial turnover. In general, the literature suggests that they are likely to both reinforce monitoring on managerial activities and induce disciplinary takeovers, cuts in corporate compensations, and CEO turnover (Ferris et al. 2007; Fich and Shivdasani 2007; Humphery-Jenner 2012).

In light of the discussion above, it becomes particularly important to consider the empirical evidence about the relations between the occurrence of an SCA and features and behavior of the target company.

Empirical Evidence About Causes and Effects of SCAs

As it will be clearer to the reader by reading this section, the behavior of a target company can both *cause* SCAs and *change because of* SCAs.

Factors Affecting SCAs

The empirical literature on SCAs well established that filings are more likely against *deep-pocket* corporations, on the one hand, appearing financially vulnerable, riskier, inefficient, and/or characterized by weak governance, on the other hand.

The significant and positive relation between the incidence of SCAs and firm's assets has been observed by the empirical literature, suggesting that class lawyers decide to proceed only against firms having sufficient resources to pay a possible settlement (see, among others Francis et al. 1994; Ferris and Pritchard 2009; Gande and Lewis 2009).

According to several studies, attorneys target firms with highly volatile stock return histories. On the one hand, the susceptibility to be targeted by an SCA results to be positively related to low stock returns (see among others, Ferris and Pritchard 2009; Gande and Lewis 2009). On the other hand, a higher market-to-book ratio is negatively related to litigation risk (Strahan 1998).

Gande and Lewis (2009) further show that low profitability and inefficient financial management significantly increase firm's litigation risk. Strahan (1998) documents a significant positive relationship between the propensity to be sued and firm's risk. This evidence is confirmed for the financial sector by Dalla Pellegrina and Saraceno (2011). High leverage and free cash flow are also associated with a higher probability of being sued (Ferris and Pritchard 2009).

The incidence of SCAs is higher in firms characterized by a greater likelihood of agency conflicts: poor corporate governance is often a catalyst for SCA (Strahan 1998; Ferris et al. 2007). In particular, there is evidence that incentives paid to executives in the form of options and bonuses are associated with a higher probability of being sued through an SCA (Peng and Röell 2008; Dalla Pellegrina and Saraceno 2016).

Furthermore, some authors find that nondividend-paying firms exhibit a significantly higher probability of being sued compared to companies which regularly pay dividends (Strahan 1998). On the contrary, Francis et al. (1994) find that firms being sued have higher dividend pay-out. Regarding board size, instead, no clear-cut evidence exists about the features of the board and the incidence of SCAs.

Effects of SCA

Concerning the impact of SCAs on the target companies, scholars identify both negative "external" effects (mainly related to the market reaction and reputational effects) and "internal" corrective effects of lawsuits.

A vast literature deals with the stock-price effects of SCA: filings are associated with significant negative price reactions (Griffin et al. 2004; Ferris and Pritchard 2009; Fich and Shivdasani 2007; Gande and Lewis 2009), whereas Ferris and Pritchard (2009) find no significant price reaction at the end of the procedure. This might suggest that the stock market immediately discounts the information related to the commencement of an SCA.

SCA can significantly heighten the cost of capital (both equity and debt) and, more in general, raising external capital becomes more

difficult for the target company because of the reputational losses related to the lawsuits (DuCharme et al. 2004; Deng et al. 2014).

SCA seems to significantly influence also investment decisions of the target company. McTier and Wald (2001) find that sued firms are more likely to increase cash holdings and leverage while decreasing overinvestment and payouts to shareholders. Dalla Pellegrina and Saraceno (2011) find that SCA induces target financial intermediaries to increase the accumulation of loan loss reserves, recapitalize, and reduce dividend pay-outs. They also provide evidence of a positive contemporaneous relationship between bank profitability – measured by either the Z-score or the Sharpe ratio – and the event of an SCA. However, the study also shows that, after few months, a more cautious attitude toward risk tends to replace the search for profits. Arena and Julio (2015) confirm both that target firms accumulate more cash in anticipation of future settlements and other costs related to litigation and reduce capital expenditures.

Many authors suggest that SCAs can enhance corporate disclosure requirements and managerial duties of loyalty and transparency, since they represent a residual monitoring device in the hands of shareholders (see, among others, Mitchell 2009). Empirical evidence supports the idea that shareholders use SCAs as a disciplinary force on managers and executives (Cheng et al. 2010).

CEO turnover has also been linked to SCA (Strahan 1998; Helland 2006; Fich and Shivdasani 2007; Humphery-Jenner 2012). Humphery-Jenner (2012) also provides insight that SCA can both induce disciplinary takeovers and make tougher prospects in the executive labor market for fired CEOs. These adverse effects, directly suffered by executives, may partially restore both the deterrence function and the private enforcement function of SCA. Indeed, Ferris et al. (2007) find improvements in the board of directors, including an increase in the proportion of external directors, while Humphery-Jenner (2012) and Dalla Pellegrina and Saraceno (2016) observe negative effects on executive compensation.

Conclusions

The main message to be learned from the dense literature on SCAs is that – because of the *circularity* mechanism that involves stakeholders as damaged claimants suing the company in which they have their own stake – these tools seem to be ineffective for the purpose of compensation and deterrence. It is undeniable, instead, that they can influence the performance of a company, causing stock price variations, changing the attitude towards risk undertaking, and affecting the reputation of its management. These effects, however, if strong enough, can return to the SCA a role of deterrence through a sort of market discipline mechanism. Several scholars are, therefore, increasingly convinced that SCAs are to be included among the corporate governance instruments.

Separation of Power

Katarzyna Metelska-Szaniawska
Faculty of Economic Sciences, University of
Warsaw, Warsaw, Poland

Definition

Separation of powers is a principle pertaining to state governance, envisaging that responsibilities of the government are divided into distinct branches, in order to assure that none of these branches exercise the key functions of another. In consequence, state power is deconcentrated, and checks and balances are provided for. In economics, this principle is primarily the focus of the research program of constitutional economics (and, more broadly, public choice), emphasizing its role as a form of specialization, as well as a source of constraints enhancing the constitutional commitment mechanism. We present the theoretical economic approaches to the separation of powers, illustrating them with examples of empirical studies.

Introduction

For centuries, the structure of power in the state raised the interest of political and social thinkers, as well as practitioners. Separation of powers constituted an important focus of these considerations. The crucial aspect of this principle involves distinguishing generically distinct spheres of state action and providing that a separate body, or a group of state bodies, is responsible for operation in each of these areas. In this way, concentration of power is prevented, which otherwise could potentially lead to power abuse and excessive restraints on fundamental rights and liberty. A classic element of the principle of separation of powers is the system of checks and balances. As opposed to complete concentration (fusion) of power, separation of powers is considered an essential element of a democratic political system and “good” governance.

The doctrine of the separation of powers has its origins in ancient Greece, where the idea of governmental functions, as well as the theories of mixed and balanced government, first developed (for a detailed historical account, see Vile 1967). The term “separation of powers” itself is attributed to the eighteenth-century French lawyer and political philosopher Montesquieu and can be found in his famous *Spirit of the Laws* (1748). According to Montesquieu’s model, state authority should be divided into three branches with distinct responsibilities: the legislative, executive, and judicial powers. The first is responsible for enacting laws and the second is for their implementation, while the third is for interpreting and applying them. To promote liberty most effectively, these three powers must be separate and act independently. The tripartite division is, however, not the only possibility – other approaches have also been proposed in political–legal thought over the centuries (e.g., concepts including separate monarchy and/or local municipality powers). In fact, the structure of power in different countries is usually much more complicated. For example, the executive branch is often entitled to create certain types of legal acts or, at least,

to initiate legislative proceedings. Several areas of government activity escape the classical divisions, e.g., government performance auditing, independent central banks, and other independent agencies such as media regulators. Furthermore, *de facto* separation of powers depends not only on legal solutions contained in countries' constitutions but also on the actual political situation in a country.

Economic analysis of the separation of powers is primarily the domain of constitutional political economy (constitutional economics) or, more broadly, public choice. Viewed from an economic perspective, separation of powers is "a structural element, which is a necessary (but not sufficient) condition to protect individual liberty when citizens (principals) have delegated powers to political decision makers (agents) in order to benefit from specialization (division of labor)" (Salzberger and Voigt 2009, p. 198). As these authors emphasize, this concept may operate at various levels: (1) the separation of functions (i.e., separation between the constitutional and post-constitutional stages, as well as between "rule making, rule execution and rule adjudication" in the latter stage), (2) the separation of agencies (between the legislature, executive, and judiciary active in the post-constitutional stage, as well as the constitutional court which enforces the constitution in the first place), (3) the separation of persons, and (4) the structure of interrelations between the divided branches of powers (either pure separation or checks and balances and the latter either on the level of decision making as, generally, in presidential systems or on the level of persons as in many parliamentary systems). Constitutional economics sees the main function of the constitution for the economy as a commitment mechanism; therefore, in studying the economic effects of constitutions, proponents of this approach devote particular attention to constraints which the constitution places on those in power in order to ensure that the promises that they make do not remain mere empty declarations. A fundamental source of such constraints is the separation of powers.

In this entry, we present the theoretical economic approaches to separation of powers, illustrating some of them with examples of empirical studies.

Economic Approaches to the Separation of Power

In theoretical economic studies, the problem of separation of powers is viewed from various perspectives. The latter are then often allowed to interpenetrate themselves as fundamental frameworks for more detailed empirical studies of the determinants and economic effects of separation of powers. Therefore, we supplement the theoretical discussion provided below with some examples of empirical studies.

Firstly, the constitutional principle of separation of powers is approached by economists as a certain type of specialization, where the legislature constitutes a forum for political bargaining at relatively low transaction costs, the hierarchically constructed executive allows for mitigating the costs of law implementation, and the judiciary supplies neutral interpretation of law ensuring that commitments of members of the legislature made during the bargaining process gain credibility.

Secondly, separation of powers is treated as separation of a political cartel. This classical approach of economists to the analysis of the structure of power within the state stems from the assumption that from an economic point of view the state is a monopolist in the exercise of institutionalized coercion. Separation of powers causes destabilization of the political cartel that could emerge in the event, whenever a certain group (e.g., political party) took control over this monopoly. To identify the particular effects of introducing separation of power for various actors within the state, it is, however, crucial to distinguish whether this separation resembles horizontal or vertical (functional) separation of a monopoly (this important observation is particularly attributed to Brennan and Hamlin (1994)). Economists typically agree that while executive–legislature relations, bicameralism,

and independence of the judiciary are mainly expressions of horizontal separation, federalism and decentralization are considered primarily as forms of vertical separation of powers. Empirical studies concentrate, in particular, on economic effects of presidential versus parliamentary systems (e.g., Persson and Tabellini 2003; Blume et al. 2009), as well as decentralization (e.g., Thießen 2003; Enikolopov and Zhuravskaya 2007). For more examples and a further discussion, see Voigt (2011).

Thirdly, separation of powers is analyzed in relation to the model of demand and supply of legislation and the role of interest groups in this setting. Two conflicting views emerge in this respect from an old debate on the constitution-making in the United States (see, e.g., on the one hand Beard (1913/1986), Posner (1986), and Tollison (1988) and on the other hand Macey (1987)). The first one regards separation of powers as the centerpiece of interest group bargains which the constitution itself is thought to represent. The effects of this are that the constitution hinders progressive change and the general society's voice in politics (Beard 1913/1986), increases the persistence of special-interest legislation (e.g., Crain and Tollison 1979), and ultimately furthers transfer of wealth from the general population to well-organized special-interest groups. According to an alternative view, separation of powers constitutes the basis for a "credible constitutional method of constraining rent seeking" undertaken by special-interest groups (Macey 1987, p. 76). Constitutions, establishing the structure of power, lay down the meta-rules that interest groups must conform to in order to successfully pursue the enactment of laws that they seek for their clients. These rules, including in particular the separation of powers, determine the level of transaction costs that such groups must bear when they attempt to accomplish the enactment of desired legislation. The higher these costs are at the constitutional level (i.e., the more it costs an interest group to obtain desired legislation), the lower the supply of special-interest legislation in a society and the less detrimental their activity to the working of the economy overall.

Fourthly, separation of powers also affects policy making by exerting influence upon the manner of exercising power within the state. Instead of hierarchical relationships, it introduces equivalency of actors and the necessity to bargain in order to implement new solutions. The need for cooperation between branches of power causes that they begin to act strategically vis-à-vis each other. The view at separation of powers from the perspective of bargaining models, describing strategic interactions between veto players (organs, powers, actors) influencing policy decisions, shows in what way these decisions depend on preferences of branches of power participating in the enactment of laws and the structural rules of these interactions defined in the constitution (for a detailed overview, see Cooter 2000).

Finally, literature concerning the significance of the number of veto players for policy making and its effects is naturally closely bound with the discussion presented here relating to constitutional separation of powers. In fact, Voigt (2011, p. 234) refers to the number of veto players in the state as "the new separation of powers." According to this approach, policy change or reform is more difficult when there exist numerous veto players. Each additional veto player, understood as a political actor capable of blocking policy change, "either shrinks the set of policies that can defeat the *status quo* or leaves it unchanged" (Gehlbach and Malesky 2010, p. 957). Therefore, policies are expected to be more stable when the number of veto players increases (Tsebelis 1995, 2002). One should however bear in mind that this may be desirable when commitment to a given policy is needed (Keefer and Stasavage 2003), but it will be unfavorable when policy change is required (Cox and McCubbins 2001). To address this problem, Gehlbach and Malesky (2010) provide a formal model and show that as the number of veto players increases, it becomes less likely that policies bringing benefits to special-interest groups will supersede the *status quo*. This is because such narrow, organized groups must compensate each veto player for opting for policy change instead of preserving the *status quo*. In certain contexts, this implies that changes in policy will actually be

greater when veto players are numerous than when their number is not large. Empirical literature initiated by Henisz (2000) argues that higher numbers of veto players correspond to better economic performance in terms of investment (more veto players result in stronger political constraints and less discretion in political decision making) and, ultimately, also economic growth.

An important place in the considerations of separation of powers from an economic perspective is devoted to the problem of independence of the judiciary and its position within the structure of power in a state. In this context, an independent (constitutional) judiciary is often regarded as the final stage in converting promises made by representatives of state power into credible commitments or a solution to the “dilemma of the strong state,” i.e., protection of citizens from the discretionary infringement of their rights by the state (Feld and Voigt 2003; Voigt et al. 2015). An independent judiciary can also be regarded as an additional veto player in the structure of power and therefore may constitute a further constraint on this power enforcing credibility of policy makers’ commitments. Empirical studies (e.g., conducted by the aforementioned authors) confirm the relevance of *de facto* judicial independence for economic growth in a global sample; this factor is also found to matter for successful economic transition of post-socialist countries of Europe and Asia (see Metelska-Szaniawska 2016).

Theoretical and empirical economic studies also concern the delegation of powers to independent bodies within the system of powers in the state which escape the classical tripartite division, such as central banks (in particular, in the context of their relevance for inflation – see, e.g., de Haan and Klomp 2010), prosecutors (e.g., van Aaken et al. 2010), auditing bodies (e.g., Blume and Voigt 2011), and other regulatory agencies specializing, e.g., in supervising liberalization, privatization, and regulation (in the field of telecommunications, the media, electricity, food safety, etc.). The establishment of independent regulatory agencies is based upon the assumption that their independence will create peer pressure and reputational incentives, leading to more

expertise-based decisions instead of the pursuit of short-term policy-driven objectives (Majone 2001). The independence of such regulators, perceived as trustees acting in the public’s interest and enhancing credible commitment of the government, rather than being mere agents of political parties in power, eventually leads to a higher quality of regulatory decisions.

Conclusions

Economists have developed a number of approaches to the analysis of separation of powers, which considerably enrich the traditional constitutional–legal scholarship. Some of these studies focus on providing new theoretical arguments and strengthen (or, in some cases, question) this principle’s conventional justification. Other works, including empirical analyses, bring valuable original findings regarding the manifold consequences of the functioning of separation of powers in constitutional systems around the globe, linking developments from the political sphere with social and economic outcomes. While, as presented in this entry, many fundamental issues have already been resolved, as new questions keep arising (concerning, e.g., supranational governance structures), the future outlook for research in this area is promising.

Sex

Samuel Cameron

Division of Economics, University of Bradford,
Bradford, UK

Definition

This entry looks at the law and economics of sex defined as the exchange of sexual acts which may be intercourse for procreative reasons or various forms of recreational exchange. The key issue in regulation is the matter of consent although this has frequently been attenuated by religious and moral considerations.

Commodity or Service

The economic analysis of sex is to treat it as a commodity or service. This is now reflected in the economic literature on happiness some of which includes frequency of sexual outlets as a determinant of subjective well-being (Blanchflower 2003). Much of early and current literature on the law and economics of sex is concerned with the normative issue of whether prostitution should be legal or not.

Some would take the position that sexual services are inalienable rights which should not be traded. This can also be applied to the selling of one's eggs or semen to others to overcome infertility. The regulatory issue here is whether money should exchange hands in return for sexual services. The other key transactional issue, in the area of sex, is consent between the parties. In the

Samuel Cameron has retired.

case of prostitution, the presence of monetary exchange, in itself, implies consent. Prostitution represents a conventional economic market where sex is bought and sold. However, making it illegal makes it difficult to draw up and enforce contracts regulating the transaction (see Della Giusta (2010); Jakobsson and Kotsadam (2013); Kotsadam and Jakobsson (2014); Immordino and Russo (2015); Scandizzo and Ventura (2015); Cho (2016)). Sexual transactions, outside of prostitution, operate in an informal market where there may be implicit contracts. That is, gifts or economic support, for example, may be given with an expectation of sexual reciprocation. The ambiguity of such situations may be connected to the issue of rape which can be seen as a transaction completed by coercion (physical or otherwise) against the will of one of the parties thus meaning there was no consent.

Sex Market

The implicit sex market is further complicated by the institution of marriage. Sexual trade may reflect an enforced case of unjustly unequal exchange where individuals are driven by a power imbalance into surrendering their inalienable rights. This takes us to the Marxist-Feminist position that marriage has been, in many times and places, a form of prostitution hidden behind a veil of respectability.

Marriage is traditionally connected to non-recreational sex that is sex for the purpose of producing progeny. One economic view of marriage is that it may be an efficient means of internalizing transactions costs, of obtaining recreational sex, in an ongoing relationship. We can see a logical economic rationale for gay marriage, in addition to any arguments of gender equity. This may be contrasted with the striking remarks of economist and Supreme Court Judge Richard Posner that it is not rational to choose to be homosexual (Posner 1992).

Traditional legally sanctioned monogamous marriage is a means of internalizing transactions costs, of sexual transaction, but this is not the purpose for which it was devised. The origins of

state-regulated marriage arrangements lie in religions some of which support nonmonogamous outcomes. It is also geared primarily toward the rearing of children. It is logical that universal monogamous contracted marriage may not be the most socially efficient institution. Accordingly we find other arrangements most notably cohabitation but also ad hoc adultery/infidelity, polygamy, LATs (living alone together separately), polygyny, orgies, polyandry, and “swinging” (organized temporary partner swapping within a group of couples). We also find other informal but semiorganized markets such as the case of “groupies” in popular music and showbiz where the groupie fan might offer sex as an informal payment to a paid protector of the star as a means of increasing the chances of offering free sex to the star.

Institutional Forms of Sex Trade

The use of different institutional forms of sex trade can be attributed to three interrelated factors – frequency of sexual activity, desire for variety of partners, and desire for variety of sexual performance. Partners may differ with respect to desired frequency of sexual activity. If this is so in a monogamous union, we have a disequilibrium in a situation of bilateral monopoly. A solution to this can be sought by recourse to either a secondary informal market – what is conventionally termed “adultery” or “infidelity” or may more neutrally be termed “partner out trading” (Cameron 2002) or the formal market of prostitution. These are consensual extended markets. The disequilibrium might also be seen as a driving force in nonconsensual additions to sexual activity, that is, rape. There is a long historical tradition of arguing that prostitution might be socially desirable as a means of providing a substitute good for rape for the disequilibrated consumer. The same arguments about frequency apply to desire for variety of partners.

Desire for a variety of partners may, to some extent, be a desire for variety of sexual acts as the designated partner may not wish to engage in the full menu of sexual acts demanded by the variety-

seeker. Thus we have types of sex. Economists can treat each type as a separate commodity or service, or they can regard the different types as product differentiation where each type has different characteristics in different proportions. Partners implicitly trading sex can differ in terms of their desires along the spectrum of such characteristics. They can also differ in their preferences for the relative amount of recreational versus reproductive sex. This will be reflected in conflict about the optimal amount of use of contraception.

Sex is not a unified product and can be performed in a number of different ways. These include buggery, bondage, use of capital goods (such as sex toys) for enhancement, and sadomasochism. Some aspects of these have regularly been subject to strong legal regulation based on social norms rather than law and economics reasoning.

Much of the historical debate around the status of buggery is related to issues of sexual identity and religion. In England, the Buggery Act of 1553 was predicated on the idea that unnatural sexual acts against the will of God should be prohibited. The Act was not fully repealed until 1967 when homosexual usage ceased to be an offence. The US Supreme Court ruled in 2003 that sodomy laws were unconstitutional; however, some states and the US military continued to attempt to have their own sodomy laws. In Germany, the laws were repealed in the late 1960s but not fully (i.e., removal of punishment of homosexuals) until 1989 (East) and 1994 (West).

Sadomasochism has proved a problematic area because of the matter of consent (Bennett 1994). Traditional microeconomic theory and welfare economics would seem to suggest that consensual sadomasochistic sex is potentially a socially efficient arrangement. The landmark case for the contest of this view is the “Spanner” action (the case of *RvBrown*) in the UK (Thompson 1994). The appeal against the decision to convict consensual sadomasochists for assault was heard in March 1993. The backdrop to this was that SM was not illegal as there was no law on it, but there was a precedent in the Donovan case of 1934 where a man had lost his appeal against an assault

conviction. In that case, the other party had consented to the treatment and continued to maintain this consent. There was also no accusation of any kind of what we would now call “grooming” which would fall under the category of coercion and thus erode consent. There has been continued debate about this case, but the UK continues to maintain the stance of illegality in contrast to more liberal regimes like Germany and Australia. In the USA, there is a lack of a clear federal law, but individual states continue to prosecute under the same assault grounds, as in England, even when consent is clearly present.

So, the basis for these convictions as assault, rather than legitimate sexual exchange, would seem to be on grounds of inalienable body rights as with blood, semen, etc. That is, an individual does not have the right to choose to be assaulted for the purpose of sexual gratification. The case of bondage without sadomasochism is different if an individual who has been rendered unable to move during the sexual acts has consented to be rendered immobile, then they cannot be deemed to have been coerced.

Any of the above variations in sexual activity is subject to regulation on grounds of by-products of them being “indecent” if the assault claim is not used or cannot be used. For example, if the parties produce any media (such as films or writing) as a by-product of these activities, these can be treated as pornography.

There are, as we have seen, a wide variety of formal and informal market arrangements for sexual trade. The Chicagoan law and economics approach would argue that the regulation of these should seek to produce a social welfare-maximizing outcome. In practice, this is attenuated by the historical legacy in legal systems of religious and ethical traditions that may not necessarily conform to socially rational choice.

Definition

The commission of an act that is defined by the law as sexual (usually involving a sexual act or touching or display of a part of the body typically associated with sexual behavior) and to which the victim has not given consent or is unable under the law to give consent. The legal absence of consent often turns on the use of force or threat of force against the victim or another person; the unconsciousness, impairment, or intoxicated state of the victim; the use of fraud in obtaining consent; the age of the victim; or the use of illegal means of obtaining consent (e.g., money). This class of crimes includes rape, statutory rape, child molestation, sexual assault, prostitution, peeping-tom offenses, and the creation, possession, and distribution of child pornography.

Sex Offenses

Abstract

Sex offenses today may be generally defined as acts of a sexual nature to which a victim has not given legal consent. This broad definition covers many different types of behaviors, but almost all individuals in the U.S. (and in a few other jurisdictions) who are convicted of committing any crime in this category are subject to unique postrelease regulations such as registration, public notification, and residency restrictions. In this entry, we briefly examine the scope of sexual offending in the U.S., the utility of the economic model of crime in understanding sex offender behavior, and the rise of

Introduction

Sex offenses constitute an ancient and important category of crime. Over the course of history, many kinds of sexual acts have been criminalized, including encounters in which consent was not at issue, such as sodomy, adultery, homosexuality, and fornication. In a large number of jurisdictions today, acts of this sort are no longer criminally prohibited; the criminalization of a sexual act instead turns primarily on lack of consent. For purposes of this entry, a sex offense is defined as

the occurrence of a sexual act, a sexual touching, or a display of body parts considered to be sexual in nature, coupled with actual or legally imposed lack of consent on the part of the victim or society.

This definition evolved from a prototypical sex offense, rape, which was defined in the English Common Law as “the carnal knowledge of a woman [by a man] forcibly and against her will” (Tucker 1803, p. 209). Lack of consent is no longer defined to include only those situations in which an offender uses physical force to overcome active resistance by a victim. Depending on the jurisdiction, lack of consent may include anything short of actual verbal and physical consent to the activity, and even actual consent is not sufficient when the victim is considered legally incapable of giving consent. Intercourse is not a required element of many sex offenses; touching, display, or even the possession of a display can suffice. Increasingly, sex offense statutes treat men and women symmetrically.

As a class, sex offenses include crimes as varied as rape, prostitution, child molestation, possessing child pornography, and peeping-tom behavior. Despite this diversity, in the United States, those who commit these crimes, upon conviction and release, are often subjected to the same novel and extensive postrelease regulations, which may include registration, public notification, civil confinement, and residency restrictions, among others. The scope and severity of these laws makes studying their predicted and actual consequences not just academically interesting, but important from a policy perspective. Perhaps it is not surprising that the traditional economic approach to crime has been questioned when applied to sex offender behavior, as sex crimes appear to some to result from inexplicable impulses or other irrational drives and thus may be undeterrable. This distinction may explain why convicted sex offenders are both uniquely and uniformly subject to these unorthodox postrelease regulations: if sex offenders are irrational and incorrigible, postrelease laws ought to focus on incapacitation rather than deterrence.

This entry will begin in Part II by providing some rough statistics on the relative frequency and diversity of sex offenses, primarily relying

on data from the U.S. Part III will briefly recount the origin and evolution of postrelease sex offender regulations and the current state of these approaches in the U.S. and other countries. Part IV will apply the traditional economic model of crime to sex offending behavior, with a focus on first describing and then understanding the advantages and disadvantages of the postrelease regulation of sex offenders. An important preliminary to this discussion will be the basic assumptions of the economic model of crime and how alternative models of sexual deviance can be useful for understanding relevant policy developments, particularly why punishments for sex offenses often differ from those of other crimes. Finally, Part V will describe the major studies and the current state of knowledge on the broad impact of sex offense laws, with a focus on the consequences of postrelease laws on crime rates, victim behavior, the geography of victimization, offender welfare, and other collateral consequences, such as housing price effects.

The Relative Frequency of Sex Offenses

Violent crime rates in the U.S. plunged over the course of the 1990s and have continued their general decline throughout the 2000s. Sex offense rates have followed roughly the same trend. Data from the FBI’s Uniform Crime Reports (UCR) show that reports of rape incidents declined from 39.2 per 100,000 in 1994 to 25.2 per 100,000 in 2013. Furthermore, the number of persons arrested for rape, prostitution, and other sex offenses each fell by over 30% between 2004 and 2013: specifically, arrests for rape fell by 30.3%, arrests for prostitution and commercialized vice fell by 35.8%, and arrests for all other sex offenses fell by 34.4% (United States Department of Justice 2014).

Not all crime incidents are reported to the police, however, and sex offense statistics may be particularly vulnerable to downward reporting bias. Indeed, according to data from the Bureau of Justice Statistics’ (BJS) National Crime Victimization Survey (NCVS), the fraction of rapes and sexual assaults reported to police was similar to

other crimes in 2003 at 56%, but by 2011, this rate had fallen precipitously to 27%, which is significantly lower than reporting rates for other violent crimes (Truman et al. 2013, Table 1). Nevertheless, NCVS data also show a decline of even greater magnitude in *victimization* rates for rape or sexual assault – from 4.3 victims of rape/sexual assault per 1,000 in population over age 12 in 1993 to 1.3 per 1,000 in population over age 12 in 2012 (Truman et al. 2013, Fig. 3).

Many distinct crimes are included under the broad definition of sex offenses; unfortunately, data on sex offenses are often only collected and/or labelled at relatively aggregate levels, such as “rape” or “other sexual offenses.” For instance, UCR incidents are reported only for rape; UCR arrests are reported for rape, prostitution, and other sexual offenses; and NCVS victimization data include rape, sexual assault, and sexual contact with or without force. As a consequence, identifying and measuring trends with respect to specific sex offenses in the U.S. can be difficult. The FBI’s National Incident Based Reporting System (NIBRS) collects information on a more detailed list of offenses (specifically, forcible rape, forcible sodomy, sexual assault with an object, forcible fondling, statutory rape, incest, prostitution, and pornography), but even as of 2012, NIBRS covers only 33% of all UCR reporting agencies, making reliable comparisons over time difficult.

Sex offenses may be committed by first-time sex offenders or by recidivist sex offenders who have committed similar crimes in the past. This distinction is of course not unique to sex offenses, but it is an important one in this context because many laws in the U.S. specifically target reducing sex offender *recidivism* rather than deterring first-time offenders. Using administrative data from New York State, Sandler et al. (2008) show that 95% of sex offense arrestees between 1986 and 2006 were *first-time* sex offenders. More comprehensive evidence exists on the fraction of convicted sex offenders who commit another sex crime after leaving prison: using detailed information on all sex offenders released from prison in 15 states in 1994, Langan et al. (2003) find that, within 3 years of release, 5.3% of these previously

convicted sex offenders had been rearrested for a sex crime. The number was somewhat lower for convicted child molesters, 3.3% of whom were rearrested for another sex crime against a child within 3 years of release. To provide some measure of comparison, the overall same-crime rearrest rate for robbery was 13.4% and for assault 22.0%; homicide was smaller at 1.2% (Langan and Levin 2002). Overall sex offender recidivism, as opposed to same-crime recidivism, was much higher, with 43% of released sex offenders being rearrested for some crime within 3 years. However, even this rate is substantially lower than the analogous rate for other kinds of convicted offenders, who had an overall rearrest rate of 68%. There can, of course, be different definitions of recidivism and different follow-up periods, which might imply higher recidivism rates. For a comprehensive review of relatively recent literature on sex offender recidivism, see Soothill (2010).

Postrelease Sex Offender Laws

Even against a backdrop of declining sex offense rates and relatively low recidivism levels, the policies that legislatures and law enforcement agencies in the U.S. have employed in recent years to reduce the frequency of sex offenses differ significantly from those traditionally used to combat crime. Criminal punishment in the U.S. and other western countries almost exclusively involves incarceration (and postrelease supervision) or fines. While these forms of punishments are also deployed against sex offenders, post-release sanctions play a much larger role in policy discussions and scholarly research. These regulations were enacted in hopes of dramatically curtailing recidivism by essentially incapacitating convicted sex offenders through residential isolation and additional monitoring and by notifying the public about these individuals in the hopes that potential victims might take precautions to protect themselves.

The Rise of Sex Offender Laws in the U.S.

The first modern wave of concern over sex offenses in the U.S. ran from the 1930s through

the 1960s (Thomas 2011). According to Thomas, there is no evidence that this concern was prompted by an increase in sex offense rates; rather, the image of the “sexual psychopath” somehow gained currency and fear of and focus on sex offenses became commonplace. The first state-level registration laws specifically targeting sex offenders were enacted during this period. Registration laws can be generally defined as laws imposing a requirement that individuals at higher than average risk of committing a crime – i.e., individuals previously convicted of certain sex offenses – update law enforcement authorities at regular intervals with their current addresses, activities, and identifying information. Despite this earlier era of fear and legal innovation, it was only much more recently – not until the late 1980s and early 1990s – that state legislatures became especially interested in the threat posed by sex offenders, often as a result of well-publicized abductions of children by individuals who had previously been convicted of similar crimes. By 1989, 12 states had created sex offender registries.

U.S. congressional involvement in this area began in earnest in the aftermath of a 1989 attack on 11-year-old Jacob Wetterling, which led ultimately to federal sex offender registration legislation in 1994 (The Jacob Wetterling Crimes against Children and Sexually Violent Offender Registration Act). This law mandated that states build sex offender registries that, at a minimum, recorded the names and addresses of offenders convicted of offenses against children or sexually violent crimes for a minimum of 10 years, for the confidential use of law enforcement (and other government authorities, in some instances), with offenders required to verify their information every year.

In 1996, the U.S. Congress enacted Megan’s Law (the name of the law being a tribute to Megan Kanka, a young victim of a previously convicted sex offender), which effectively required the *release* of relevant sex offender registration information to the public. Such community notification laws make mandatory (or, in some cases, simply allow) the dissemination of registration information to the public, either actively or passively, with

the application of the law sometimes limited only to high-risk classes of offenders. Notification can occur in several different ways under these laws, including by allowing the public to physically inspect paper registries, by publishing notices in newspapers, and/or by actively informing potentially interested residents through the mail or through an in-person visit by a law enforcement officer. Primarily, however, community notification is handled via easily accessible webpages, which the public can use to search for offenders by name or for offenders living near particular addresses. Meanwhile, the Pam Lychner Sexual Offender Tracking and Identification Act of 1996 created a National Sex Offender Registry (NSOR) to address the difficulties that result from interstate migration by convicted sex offenders. Additional federal laws were passed during the late 1990s to extend the scope and increase the coverage of registration and notification and to address concerns related to child pornography on the internet.

The turn of the millennium saw the U.S. enact yet more extensive federal sex offender legislation. For instance, the Campus Sex Crimes Prevention Act of 2000 obligated all sex offender registrants taking courses or working at a university to affirmatively notify the administration of their registration status. The 2003 Prosecutorial Remedies and Other Tools to end the Exploitation of Children Today (PROTECT) Act required that states maintain online websites for their registries and worked to make these websites more accessible. In 2006, as part of the Adam Walsh Child Protection and Safety Act, the U.S. Congress enacted the Sex Offender Registration and Notification Act (SORNA), which further expanded the scope of registration and notification laws, and which developed a three-tier system of classifying sex offenders. Offenders are ranked based on their convictions; tier one offenders must register for 15 years minimum, second tier offenders for 25 years, and third tier offenders for life.

The Diversity and Intrusiveness of Sex Offender Laws in the U.S.

Although federal involvement has been substantial in this area, most innovation has occurred at

the state or local levels of government (indeed, the federal laws were built on state models). Post-release restrictions of seemingly every imaginable variety have either been experimentally implemented or currently exist in the U.S. at the state or local level.

For example, one common trend during the last 20 years has been the increasingly intensive use of sex offender residency restrictions. These restrictions are mandatory limits on where registered sex offenders may reside, with permissible areas defined by whether the residence is more than a minimum distance away from all places that have certain characteristics or fit into certain categories (e.g., schools, day care centers, etc.). As of 2014, approximately 33 states have implemented sex offender-related residency restrictions. A number of jurisdictions now also enforce lifetime GPS monitoring of convicted sex offenders. Other jurisdictions impose extensive employment restrictions. For example, in Louisiana, registrants cannot operate any bus, taxicab, or limousine, or work in any service position that would involve entering a residence (La. Rev. Stat. Ann. § 15:553). Travel restrictions are also common: in Illinois, registrants must provide law enforcement with a detailed travel itinerary if they intend to be away from their registered residence for more than two days (730 Ill. Comp. Stat. 150/3). Other jurisdictions ban registrants from public libraries, hurricane shelters or emergency shelters, or parks and playgrounds (see Iowa Code § 692A.113(f), Associated Press (2005), and Warren Mun. Code 22-140, respectively).

Other innovations by state and local authorities appear to be uncommon, but nonetheless intrusive and sometimes inexplicable. In Tennessee, certain registrants may not “[p]retend to be, dress as, impersonate or otherwise assume the identity of a real or fictional person or character or a member of a profession, vocation or occupation while in the presence of a minor” (Tenn. Code Ann. § 40-39-215(a)(1)). In California, among a number of other states, a registrant on parole may not live with any other registrant in a “single family dwelling,” although a statutory exception allows married or related registrants to cohabitate (Cal. Penal Code § 3003.5(a)). In Florida, Tennessee, and

Texas, sex offender registrants must carry special driver’s licenses or identification cards that clearly indicate that they are convicted sex offenders and that they are required to register (Fla. Stat. § 322.141; Tenn. Code Ann. § 55-50-353; Tex. Transp. Code Ann. § 521.057).

After being enacted, these restrictions have often been retroactively applied, meaning that many sex offenders released years – even decades – earlier are still required to comply, notwithstanding the fact that the law was passed many years after these offenders committed their offenses. Governments are free to do this because postrelease sex offense regulations are not formally considered punishments, although there is little doubt that they are punitive in effect and courts and scholars in the U.S. increasingly view them as forms of punishment. Rather, these post-release laws are considered regulations, designed to reduce the likelihood that a convicted sex offender will reoffend upon his release from prison. While registration, community notification, and residency restrictions may be the best known of these laws, perhaps the most extreme instance can be found in the broad civil confinement authority granted to corrections officials by some state legislatures. Specifically, because constitutional or fairness considerations bar continuing *punitive* incarceration beyond the length of an offender’s official sentence, legislatures have simply enacted civil confinement measures that allow authorities to continue to imprison a sex offender even after his sentence has expired if he is still deemed to pose a threat. The U.S. Supreme Court upheld this practice in *Kansas v. Hendricks*, 521 U.S. 346 (1997).

During this period of steady growth in the scope and intensity of postrelease sex offender regulation, many of those allegedly harmed by these laws have challenged their legality, principally arguing that their retroactive application is a violation of the Ex Post Facto Clause of the U.S. Constitution. In 2003, the U.S. Supreme Court set the tone for these kinds of arguments in *Smith v. Doe*, 538 U.S. 84 (2003), in which a majority of the Justices ruled that the Alaska registration law before the Court was not a form of punishment, but rather a regulation in the interests

of public protection and, therefore, could be applied retroactively. As the growth in the breadth (and number) of postrelease sex offender laws has continued apace in recent years, *ex post facto* legal challenges have met with more success, at least in some jurisdictions.

Sex Offender Laws: International Context

The U.S. is not alone in its growing alarm over sex offender recidivism and in at least contemplating the use of postrelease sanctions designed to reduce such recidivism. Thomas (2011) provides extensive detail on these international developments through 2010. At a minimum, the United Kingdom, Ireland, France, Canada, Australia, South Africa, Kenya, Jamaica, and South Korea have enacted some form of registration law. The European Union allows for a comprehensive approach to sanctions for certain sex offenses and has attempted to enforce criminal record sharing and reciprocal bans for convicted sex offenders from working with children (Smith 2011). However, none of these E.U. directives have created anything like the registry or notification procedures that one sees in the U.S.

As of 2014, the U.S. allows greater access to registration information than any other country. In a few countries (e.g., the U.K.), laws do permit the disclosure of information about an offender's status and criminal history to people who have a close connection to a child who may have unsupervised contact with someone suspected of being a sex offender. However, this information is considered confidential and cannot be shared with others. In 2001, South Korea began publicly disclosing information about high-risk offenders, but in 2003, this practice was deemed unconstitutional. Today, however, South Korea does rely on GPS tracking of convicted sex offenders. In Manitoba, Canada, the public can access limited information on registered offenders who pose a great risk of reoffending. Western Australia began disclosing information about convicted sex offenders to the general public in 2012 (Whitting et al. 2014). In 2014, a bill in Canada that proposed tougher penalties for sexual predators included a provision allowing for the public disclosure of names and addresses of some registered

sex offenders, in order "to encourage protecting children from past proven behaviours" (Connolly 2014), but at the time of this writing, this proposal has not been made law.

Sex Offender Laws and the Economic Model of Crime

The economic model of crime conceptualizes a rational potential offender who chooses to engage in crime when the expected benefits of committing the crime outweigh its expected costs. Expected costs in most contexts are a function of the probability of punishment, the punishment if convicted (e.g., prison, fines, or social sanctions, including shaming punishments and isolation), and the direct costs of committing the crime (e.g., travel, or procuring a gun). Expected benefits can either be tangible (e.g., money or goods) or intangible (e.g., pleasure or other psychological benefits). A more severe punishment or a higher likelihood of detection should reduce the proportion of potential offenders who choose to commit a crime in this model. Thus, while other purposes of punishment (such as incapacitation, rehabilitation, or retribution) may reduce crime or improve social welfare, the economic model of crime focuses primarily on the potential deterrent effect of criminal policies and regulations.

Are Sex Offenders Economically Rational?

The relevance of the economic model of crime to the commission of sex offenses and to the understanding of sex offender behavior is not at all obvious. At least in part, this observation stems from the fact that, to many, sex offenses appear simply inexplicable – i.e., people have trouble comprehending why anyone would benefit *at all* from committing most such crimes (e.g., Stinson et al. 2008, p. 3). The motivations behind acquisitive crimes and even certain crimes of violence, by contrast, are easier for many to understand. Sex offenses are also often viewed as impulsive (although many crimes in this category are clearly not impulsive and require extensive planning – the production of child pornography or prostitution, for instance). By these lights, certain sex offenders

appear to be unable to make conscious decisions about whether they ought to commit these sorts of crimes. A consequence of this perspective is that sex offending is regularly associated with mental illness or some other immutable or biological trait (White 1999, pp. 357, 392–394).

If one begins with the assumption that sex offenders cannot appreciate the nature of their conduct or are unable to control their behavior *at all*, the economic model of crime with its focus on deterrence plays no useful role in understanding or preventing criminal behavior. Instead, the policy goals of incapacitation and rehabilitation must take center stage. In this vein, researchers have proposed many theories (not mutually exclusive) to account for sexually deviant behavior. Scholars developed these noneconomic models in part to reduce the extent of offending by accurately identifying and treating those who are at risk of committing such offenses (as opposed to deterring them). Stinson et al. (2008) summarize and integrate this body of literature, describing biological theories, cognitive theories, behavioral theories, social learning theories, personality theories, and evolutionary theories.

But in all cases, these models do in fact assume that sex offenders retain at least some ability to respond to their environment, and accordingly, the economic model of crime can be profitably applied to understanding sexually criminal behavior. Moreover, alternative causal theories are complementary to the economic model because the former aid in understanding the psychological benefits offenders pursue when offending and how they perceive (and misperceive) their environment, particularly whether the behavior the potential offender is considering is truly transgressive and, if so, whether it is likely to result in apprehension and punishment.

The Behavioral Consequences of Sex Offender Laws

For at least two reasons, the theoretical and empirical research on sex offenders as economic actors has focused to a considerable degree on the behavioral consequences of postrelease regulations. First, simply examining the effects of more conventional criminal sanctions on sex offender

behavior is at best a minor contribution, at least when viewed from within the four corners of the economic model of crime. As with criminal behavior in general, more severe sentences or more policing resources may induce changes in sex offending behavior, whether accomplished in a straightforward way or through the implementation of policies likely to have the same effect – e.g., mandatory minimum sentences, three-strikes law, and so on. In essence, the basic mechanics of the economic model of crime are fundamentally the same, whether or not the crime in question is a sex offense. Second, policies such as registration, community notification, and residency restrictions are relatively novel in modern times; these sanctions could in theory be applied to other types of released offenders, but with a few notable exceptions in a few jurisdictions (e.g., elder abuse), sex offenders remain their sole targets. Sex offender behavior thus provides a unique opportunity to study empirically the effects of these postrelease laws and their complex interactions with traditional sanctions (like incarceration), all of which may push sex offense rates in different and potentially offsetting ways (see, e.g., Teichman 2005).

Consider the framework offered by Prescott and Rockoff (2011) involving a potential sex offender i who must decide whether to commit a sex offense against victim j . This decision is a function of a victim-specific probability of punishment (p_{ij}), targeting costs (c_{ij}), the level of punishment if convicted (f_i), and victim-invariant utility (benefit) of committing the sex offense relative to lawful alternatives (u_i). In this economic environment, postrelease sex offender laws – unlike an across-the-board increase in the sentencing range for sex offenses or devoting more resources to the detection of sex crime – may have the effect of altering offending behavior in multiple distinct ways.

For instance, registration may enhance police monitoring and facilitate the apprehension of registered offenders who commit crimes against local victims, thereby increasing certain victim-specific punishment probabilities (p_{ij}). Registration may also influence the behavior of nonregistered individuals because punishment (f_i) now includes a

higher future probability of detection upon release. Notification, by contrast, effectively shames sex offenders by publicly airing their personal information and criminal history, which can result in loss of employment and social ties, poor housing, and even harassment (Levenson and Cotter 2005a). For nonregistered sex offenders, notification makes the consequences of any conviction more severe (f_i). Already registered offenders, however, would face no *increase* in punishment (f_i). The relative utility of crime (u_i) would be higher under notification for already registered offenders because engaging solely in law-abiding behavior would involve more stress, loneliness, and unemployment, but the ability of local residents and acquaintances to identify and avoid these offenders would make targeting this particular subset of potential victims (c_{ij}) more difficult. Thus, the predicted consequences of notification for crime rates are ambiguous.

Sex Offender Laws and the Geography of Victimization

Postrelease laws also have the potential to alter the geography of sex offender behavior in ways both expected and unexpected. For instance, as Prentky (1996) notes, notification may “accomplish nothing more than changing the neighborhood in which the offender looks for victims” (p. 295). Agan and Prescott (2014) develop this idea in more depth; they alter Prescott and Rockoff’s (2011) framework by considering a potential offender i who is deciding whether to commit a crime against victim j in location l . The offender now additionally weighs the cost of travel to location l (c_{il}), the cost of finding a victim j in l (c_{jl}), and a location specific probability of punishment (p_{il}). Although registration and notification laws apply only to registered (convicted) sex offenders, the information these laws provide and the responses of the police and at-risk individuals may have effects on the offense locations of *all* potential offenders, both those who are registered as well as potential first-time offenders.

Using this model, one can explore the potential consequences of more registered sex offenders living in a particular neighborhood on that

neighborhood’s crime rates. When only registration and not notification laws are in effect, enhanced monitoring of registered sex offenders presumably increases the probability of punishment for sex offenses that such offenders commit near their homes (p_{il}), possibly displacing or deterring those crimes. Registration alone, however, is in theory confidential and thus seems unlikely to affect victim behavior (c_{ijl}) or the location parameters for nonregistered potential offenders. When the contents of the sex offender registry are made publicly available via notification, however, potential victims, registered sex offenders, and even nonregistered sex offenders may all change their behavior, implying ambiguous effects on crime level predictions near registered sex offender residences. Publicizing their identities may render registered offenders even more likely to offend in other neighborhoods as they attempt to reduce the likelihood of their being caught (p_{il}). Alternatively, notification might make offending more attractive to registered sex offenders (e.g., by aggravating recidivism risk factors like unemployment). Thus, if victim precaution-taking is ineffective and/or travel is difficult, registered sex offenders may find attacking near home significantly more attractive.

One key insight from this work is that post-release laws that alter the information environment generally, like notification, may affect the behavior of potential sex offenders who have never been convicted of a sex crime. These non-registered offenders may be able to use the information provided by public notification in deciding both *whether* and *where* to offend, and the changes in their decisions may have the consequence of altering the geography of sex offense victimization risk in unexpected ways. For example, if the police tend to focus their energies on monitoring registered offenders, *nonregistered offenders* may be less likely to be caught in neighborhoods with high concentrations of publicly known offenders (p_{il}). Similarly, victims may avoid registered offenders and their homes, but lower their guard around individuals who do not appear on the registry (c_{ijl}). If these factors attract nonregistered offenders to neighborhoods where registered offenders reside, these neighborhoods

may become more rather than less dangerous after notification. Whether the effect of notification laws on sex offense rates in neighborhoods with resident registered offenders is positive or negative ultimately depends on the net effect of these factors.

Empirical Evidence on Sex Offenses and Crime-Reduction Policies

The frequency and distribution of sex offenses are not only functions of traditional criminal justice policies (such as policing levels and sentence lengths), but also of the unique post release regulations to which many sex offenders are made subject in the U.S. and elsewhere. This part of the entry will begin by briefly and selectively reviewing a few recent findings with respect to the effects of traditional policy innovations in which sex offenders (or sex offense rates) are singled out by the researchers as behaving distinctively. The section will focus more heavily, however, on a growing body of work that studies the empirical consequences of postrelease sex offender laws.

The Effects of Traditional Policy Innovations

The below economic model of criminal behavior laid out previously implies that there exist many policy levers that may influence crime rates, including sex offense rates, such as the probability that an offender is arrested conditional on committing a crime and the punishment (often the extent of incarceration) if the offender is convicted of the crime. Few research papers in this arena focus *solely* on the empirical effect of general criminal justice policies on sex offense rates. However, because the major data sources, and in particular the UCR, include sex offenses as one explicit category of crime, research that reports results disaggregated by offense type will often include and sometimes discuss separately results for rape and occasionally for other categories of sex offenses.

A conventional model of criminal offending predicts that increasing the probability of punishment (e.g., through heightened detection levels or

more resources devoted to apprehension) will decrease the likelihood that an individual will choose to commit a crime. Levitt (1998) provides classic evidence for this conclusion – increases in arrest rates are associated with decreases in commission rates for all crimes, including rape specifically. However, Levitt concludes that for rape, as opposed to other crimes, the main channel through which higher arrest rates reduce rape rates is through incapacitation – that is, incarcerating sex offenders reduces the relative frequency of rape *not* because potential rapists are deterred, but instead because sex offenders, once incapacitated, commit fewer crimes. With respect to the magnitude of the effect, Levitt finds that one additional arrest for rape is associated with a reduction in the number of rapes by one-half as a result of sex offender incapacitation.

An additional method of increasing the probability of punishment, presumably through either higher arrest rate probabilities or heightened monitoring, which in turn leads to greater deterrence, is to supplement the number of police officers in a particular locale. While boosting law enforcement personnel levels does appear generally to reduce crime incidence reports (i.e., aggregate crime levels), both Levitt (1997) and Evans and Owens (2007) – using different empirical strategies – estimate no significant effect of additional police officers on rates of reported rape incidents.

The traditional punishment meted out for serious crimes is incarceration, and over the last three decades, there has been a significant increase in the number of Americans in prison. Larger prison populations have the potential for both an incapacitation effect on those in prison as well as a deterrent effect on potential criminals who infer a greater likelihood of being incarcerated if they commit crime in the future. Johnson and Raphael (2012) explore the marginal effect of an additional prisoner on total crime rates, evaluating the combination of these two effects. They estimate that an additional prisoner reduces rapes by about 0.03, a statistically significant effect, although much smaller in magnitude than the overall elasticities they estimate for property crimes (2.3) or all violent crimes (0.12).

The Effects and Implications of Postrelease Sex Offender Laws

The application of postrelease laws (including registration, notification, and others) to those who have been convicted of committing a sex offense also has obvious potential to affect the frequency of sex offenses, although not only by reducing their numbers, as is usually assumed by policymakers. These regulations are implemented ostensibly to increase public safety and prevent known offenders from reoffending (particularly, close to where these offenders live). These laws may also influence the behavior of potential victims, the police, and even individuals considering committing a sex offense for the first time, who may fear the possibility of being subjected to such regulations if apprehended and convicted of a covered offense. Perhaps surprisingly, it is theoretically uncertain whether these laws ought to reduce sex offense rates; whether there may be collateral consequences to the passage and implementation of these laws is also an important policy consideration. Several major social science research studies have explored these empirical research questions.

Registration, Notification, and Offender Behavior

Given that these laws are primarily intended to increase public safety by reducing sex offender recidivism, a clear place to start the discussion is with recent work seeking to understand whether either registration or notification (the earliest categories of postrelease sex offender laws) are effective in this regard. In the U.S., two papers that have examined national-level data on the effects of sex offender registration and notification on recidivism. Agan (2011) uses state-by-state panel data from the FBI's Uniform Crime Reports to understand the impact of registration and notification laws on rates of reported rape incidents and arrests for other sex offenses as these provisions went into effect at different times across different states. Her analysis finds no effect of registration or notification on rape rates, and no effect of registration on sex offense arrests. However, she does find some evidence that sex offense arrests decreased after the implementation of internet notification. Using individual data on all sex offenders released from prison in 1994 and followed for 3 years, Agan

also shows that convicted sex offenders released in states that had registration laws were no less likely (and if anything, more likely) to recidivate than sex offenders released in states that did not have registration laws.

Prescott and Rockoff (2011) study similar questions, but use the previously described NIBRS data, which allows for a more nuanced look at sex offense definitions and victim-offender relationships. One of their contributions is to use the number of registered offenders at the county level to separately identify the deterrent and recidivism-reduction effects of registration and notification policies. They find no discernible deterrent effect for registration laws alone but do find evidence that these laws reduced recidivism for crimes committed by offenders known to the victim (but not for those committed against strangers). Notification, on the other hand, does appear in their data to deter potential offenders (i.e., nonregistered individuals). By contrast, Prescott and Rockoff find no evidence that public notification reduced recidivism by registrants, supposedly the primary purpose of these laws. In fact, in the states they study, notification may actually have increased recidivism rates.

While there are some glimmers of hope in these results, the overall takeaway from these studies is that no reliable evidence exists that registration or notification laws increase public safety by reducing recidivism. Several researchers have performed state-specific analyses of the effects of these policies on sex offense rates and recidivism and have reached a similar conclusion (see, e.g., Tewksbury, Jennings, and Zgoba (2012) in New Jersey; Tewksbury and Jennings (2010) in Iowa; Sandler et al. (2008) in New York, among others), although the results are in no sense uniform and many open research questions remain.

Notification and Potential Victim Behavior

Notification laws were designed to reduce offender recidivism directly by influencing the behavior of potential offenders, but also indirectly, by changing the habits and activities of potential victims – i.e., community members who receive sex offender registry information. Indeed, notification policies are premised on the

idea that newly informed neighbors and other individuals at risk will engage in effective precaution-taking in response to registry information, which would in turn make it more difficult for potential recidivists both to locate plausible victims and, if one is located, to succeed at committing a crime and evading arrest. Empirical support for this premise, however, is mixed. Anderson and Sample (2008) surveyed a representative sample of Nebraskans and found that only roughly one-third of respondents reported taking any preventative actions upon learning relevant sex offender registry information. Moreover, the most common responsive action reported by potential victims in their study was simply further communicating registry information to others.

In a small survey in Ohio, Beck and Travis (2004) evaluated the precaution-taking responsiveness of individuals who were “actively” notified by law enforcement of the identities and whereabouts of nearby registered sex offenders. They found that individuals receiving notification engaged in relatively more protective behaviors. Bandy (2011), however, conducted a similar survey of households affected by Minnesota’s active community notification program (which applies to those living within approximately three blocks of a registered sex offender), but additionally surveyed a matched sample of households that were not affected by the program. Once neighborhood demographics and other confounding characteristics are taken into account, Bandy finds no significant relationship between receiving notification information and engaging in protective behaviors. She posits that because sex offenders often live in disadvantaged neighborhoods, and because individuals in such neighborhoods already engage in extensive precaution-taking behavior in any event, notification does not change the way they perceive the safety of their surroundings.

Residency Restrictions and Offender Behavior

Residency restrictions limit where registered sex offenders can live, usually by prohibiting residency within a certain distance from areas where children might congregate (such as schools, day-care centers, and sometimes even bus stops). These restrictions are real constraints; they make

it demonstrably more difficult for registered sex offenders to find stable housing. In fact, Zandbergen and Hart (2006) show that the particularly restrictive residency restrictions in Florida implied that only five percent of housing was legally available to registered sex offenders in the state. These restrictions often force registered sex offenders to live in socially disorganized, impoverished neighborhoods (Tewksbury and Mustaine 2008). These neighborhoods are likely to be less conducive to reintegration because they offer fewer opportunities for employment and social connection.

There is little research on the effects of residency restrictions on sex offender recidivism or sex offense rates more generally. The evidence that does exist, however, does not support the idea that residency restrictions reduce recidivism. Using data from North Carolina, Kang (2012) finds that offenders subject to residency restrictions are more likely to be reconvicted for a non-sex crime (a result consistent with the idea that residency restrictions make finding employment and stable housing more difficult), but also finds no evidence that they are more (or less) likely to commit another sex offense. Kang echoes the hypothesis that the adverse effects of restrictions on offending behavior generally may have their source in the social disorganization of the neighborhoods in which registered sex offenders live. One study by Huebner et al. (2014) proceeds by comparing recidivism rates of registered sex offenders who were released from prison in Michigan and Missouri before and after residency restrictions had gone into effect in those states. Using a propensity score matching design, the authors find no evidence that residency restrictions decreased recidivism levels, and in Michigan, registered sex offenders subject to such restrictions appeared to be slightly more likely to recidivate. Unfortunately, low overall recidivism rates make it difficult for the authors to be confident in this latter finding. In Minnesota, Duwe et al. (2008) study the geography of reoffending patterns of registered sex offenders *before* Minnesota’s residency restrictions were implemented, asking hypothetically whether the restrictions ultimately adopted could possibly

have made a difference in the committed crimes. They conclude that for the 224 sex offenders they evaluate, there is little evidence that any of their subsequent sex offenses would have been prevented by Minnesota's residency restrictions.

Evidence on the Geography of Victimization

Registration and notification laws as well as residency restrictions are based on the idea that sex offenders are likely to commit crimes near their home, and so restricting them from getting too close to particular victims or allowing at-risk individuals to steer clear of potential recidivists by publicly identifying where convicted sex offenders live should increase public safety. Whether sex offenders *actually* offend near their homes is an empirical question, however. Offsetting influences on the locational offending choices of registered sex offenders as well as potential sex offenders render theoretical conclusions ambiguous.

Tewksbury et al. (2008) compare census tracts in Jefferson County, Kentucky (home of Louisville), and find no evidence that a higher concentration of registered sex offenders in a census tract is associated with more sex offenses. Agan and Prescott (2014) study the effects of registration and notification laws on the geography of sex offense victimization in Baltimore County, Maryland. They find that when registered sex offenders are only subject to registration, there are *fewer* reported sex offenses in neighborhoods where registered sex offenders live. When notification about registered offenders becomes required, however, reported sex offense rates *increase* in those neighborhoods where registered sex offenders live, although overall there are still fewer sex offenses committed in these neighborhoods. Importantly, there is variation in these effects for different types of sex offenses. In particular, the findings are reversed for the crimes of forcible rape and sex offenses against children (as opposed to sex offenses against adults or peeping-tom, pornography, and prostitution crimes). For these crimes, an additional registered sex offender in a neighborhood is associated with an increase in the frequency of sex offense reports when only registration is in place but is associated with less risk once notification begins.

Collateral Consequences of Sex Offender Laws

Research has failed to demonstrate empirically the efficacy of postrelease regulations aimed at reducing sex offense rates and recidivism by convicted sex offenders. By contrast, extensive research indicates that these laws have serious collateral consequences for many community members, not to mention for released sex offenders and their families.

For instance, postrelease sex offender laws can have far-reaching consequences for the housing market. Perhaps because people fear living near convicted sex offenders, prospective buyers appear to use information on the residential proximity of registered sex offenders when deciding whether to purchase a home and what price to pay for it. In particular, evidence suggests that a registered sex offender living very nearby greatly reduces a residential property's value. Both Linden and Rockoff (2008) and Pope (2008) show that prices for homes located near a registered sex offender are significantly lower than otherwise comparable homes located away from a known sex offender's residence: Pope's results, for example, indicate that houses located within one-tenth of a mile of a convicted sex offender's home sell for roughly 2.3% less than otherwise similar homes with no registered sex offenders living nearby.

Survey evidence also shows that notification can hamper social integration and result in greater fear of crime in a community (Zevitz 2004; Beck and Travis 2004). This is true despite the fact researchers have yet to find compelling evidence that potential victims take protective actions in response to notification information or that these policies increase public safety.

Research has also shown that postrelease sex offense laws have significant collateral consequences for convicted sex offenders and their families. Surveys have found that registered sex offenders experience significant stress, isolation, fear, shame, and embarrassment as a result of being publicly identified as a convicted sex offender. Many have lost their jobs or homes or struggle with distress or depression and some also experience threats or property damage (Levenson et al. 2007). These consequences may be risk factors that lead registered sex offenders to

become more rather than less likely to recidivate (Levenson and Cotter 2005a). A similar survey studying the collateral effects of residency restrictions suggests that these restrictions also lead to decreased stability; some of the respondents in the survey even warn that this reduced stability increases recidivism risk (Levenson and Cotter 2005b).

Concluding Thoughts

A sex offense is defined as the occurrence of a sexual act, a sexual touching, or a display of body parts considered to be sexual in nature, coupled with actual or legally imposed lack of consent on the part of the victim or society. Notwithstanding the fact that reported sex offense rates have been declining over the past two decades, and despite the varied nature of crimes that are legally considered “sex offenses,” postrelease laws that broadly and uniformly apply to offenders who have committed these crimes are proliferating, from registration to notification to residency restrictions. By and large, rigorous empirical evidence offers no support for the claim that postrelease regulations have the potential to reduce sex offense rates or recidivism, despite significant research effort and decades of experience with these laws. Indeed, these regulations may increase recidivism risk for those previously convicted of sex offenses and at the same time create a culture of fear and dilute social cohesion in communities. Open questions beckon – among them the consequences of civil commitment and GPS tracking, in addition to the potential offered by innovative, local experimentation. Yet, the conclusion remains that postrelease sex offense regulations appear thusfar to be causing fear without function.

Shadow Banking

Alessio M. Paccès

Erasmus School of Law, Rotterdam Institute of Law and Economics, Erasmus University Rotterdam, Rotterdam, The Netherlands

Definition

Shadow banking is often defined by reference to what is not, namely official banking. This essay takes a different approach. Focusing on the purpose of shadow banking regulation, namely minimizing systemic risk, shadow banking is defined as leveraging on collateral to support liquidity promises.

This essay discusses the economic case for regulating shadow banking by asking three questions. First, what is shadow banking? Second, why regulate shadow banking? Third, how to regulate shadow banking efficiently? It is argued that shadow banking should be regulated because the social cost of systemic risk is not internalized by the players generating it. Moreover, because systemic risk cannot be accurately measured and priced, this essay argues that the negative externalities of shadow banking should be limited through quantity regulation – restrictions on the size of shadow banking – rather than corrective taxation.

Introduction

This essay deals with the economic rationale for regulating shadow banking. It discusses whether

the regulatory initiatives proposed by academics and policymakers are consistent with this rationale. Positing that the ultimate goal of financial regulation is to promote financial stability, shadow banking regulation is evaluated based on its ability to reduce financial instability efficiently.

Regulating shadow banking is challenging because shadow banking is often defined by reference to what it is not, namely licensed or official banking. However, such an approach does not capture the essence of the shadow banking problem. The official banking system has always implicitly or explicitly supported a significant part of what is known today as shadow banking, by way of so-called liquidity puts (Claessens and Ratnovski 2014). A liquidity put is a put option which backstops the liquidity needs of a financial institution. A liquidity put may be private, for instance from a commercial bank, or public, for instance from a central bank.

One should rather start from the observation that shadow banking is effectively banking, albeit carried out in such a way as to avoid regulatory constraints. In order for regulation to be effective in promoting financial stability, shadow banking is to be defined functionally, based on its contribution to systemic risk. The definition of systemic risk can be instrumental to measuring it (Brunnermeier and Krishnamurthy 2014). Measuring systemic risk is important. However, such measurement can never become so precise as to prevent financial crises. To define shadow banking, it is better to adopt a conceptual approach to systemic risk. In this perspective, systemic risk can be characterized as the likelihood of financial system failure, which will impair the financing of production and consumption, and thus will have consequences on the performance of the real economy.

Anchoring the definition of shadow banking to a conceptual framework of systemic risk, instead of to a list of systemically relevant activities, allows identifying shadow banking despite financial innovation and the imperfection of risk models employed by the financial industry and its regulators. One can define shadow banking by its ability to fund long-term commitments through short-term liabilities, which are considered *as*

safe as money (Mehrling et al. 2013). The implied liquidity of such liabilities makes them subject to run. A generalized run on banking institutions – both official and shadow – is a systemic risk event because it destabilizes the financial system, which becomes unable to support production and consumption in the real economy.

To preserve financial stability, regulation of shadow banking should focus on entities and transactions allowing liabilities to be accepted as a substitute for money. For the banking business to be profitable, such safe, liquid, and short-term liabilities must be invested in risky, illiquid, and long-term assets. Both official and shadow banking are to be identified in connection with maturity transformation. This is the ultimate source of systemic risk. Liquidity promises can no longer be honored when there is uncertainty on how to transform risky, long-term assets into safe, short-term ones. This situation creates panic and runs. To be sure, the maturity mismatch between assets and liabilities is not essential for shadow banking to generate systemic risk. The latter stems likewise from liquidity transformation (financing illiquid assets with liquid liabilities) and credit transformation (enhancing the credit risk of assets in order to fund them) (Adrian and Ashcraft 2016). For the purpose of the present essay, maturity transformation is to be intended broadly, as to include liquidity and credit transformation too.

The Definition of Shadow Banking in Policymaking

Defining shadow banking is challenging because it involves a variety of financial instruments, institutions, and activities, and it is changing over time. Therefore, searching for an all-encompassing definition would not take us far. Policymakers should rather define shadow banking by reference to the purpose for which it is studied. Since the shadow banking is worrisome because of its contribution to systemic risk, a useful definition needs to cover the systemic risk implications of shadow banking.

Currently, there are three approaches to defining shadow banking. Shadow banking may be

defined by the activities, the entities, or the instruments constituting shadow banking. Activity-based definitions include maturity, liquidity and credit transformation so long as they are geared towards performing credit intermediation – namely, taking savings from lenders and channeling them towards borrowers. Activity-based definitions may or may not exclude credit intermediation performed by banks, for instance because the latter engage in regulatory arbitrage. Alternatively, shadow banking may be defined by the entities carrying out credit intermediation subject to the risk of runs. Entity-based definitions typically exclude banks. One example of such entities, among many, are Money Market Mutual Funds (MMMFs). Finally, shadow banking may be defined by the instruments through which it is carried out. Take, for instance, the repurchase agreement (repo), which is functionally a contract to borrow on financial collateral. Depending on the quality of collateral, its credit enhancement and the term of the contract, a repo can generate money-like liabilities. There are several other examples of such instruments. Importantly, the list is not finite, but it includes every credit instrument that can generate safe and liquid liabilities, which are potentially subject to runs.

An instrument-based definition is a functional definition anchored to a financial instrument that may or may not yet exist. Activity-based and entity-based definitions are functional, too, because they reflect the systemic risk concerns stemming from shadow banking. However, these definitions are static due to their reliance on a list of entities and/or activities. Activity-based and entity-based definitions are useful to identify the object of regulation, whereas an instrument-based approach is more promising to adapt regulation to unknown challenges to financial stability.

Activity-based definitions are very attractive in theory. “If it looks like a duck, quacks like a duck, and acts like a duck, then it is a duck” – so the saying goes. When it comes to shadow banking, however, such definitions are very difficult to operationalize because they are either too narrow or too broad. Too narrow definitions are easy to circumvent. Too broad definitions implicitly confer discretion upon the agency that is supposed to

identify and regulate shadow banking. This may generate legitimacy concerns because identifying the financial institutions subject to regulation is a sensitive policy issue, which is usually for the legislature to decide.

The Financial Stability Board (FSB 2011) has adopted an activity-based definition, which is operationalized by reference to a broad set of nonbank entities (“credit intermediation involving entities and activities outside the regular banking system”). The International Monetary Fund (IMF 2014) has taken a completely different approach, identifying shadow banking based on issuing liabilities different from those of traditional banking (“noncore liabilities”). The IMF approach is therefore instrument-based. Both approaches support a narrow and a broad version for precautionary reasons. However, they are not comparable because the IMF definition includes banks as well. According to the FSB (2015), the narrow measure of shadow banking in 26 jurisdictions was \$36 trillion in 2014, as opposed to \$135 trillion of the official banking sector.

A Collateral-Based Definition

Choosing one approach to define shadow banking is not easy, for they all have shortcomings. Activity-based definitions are underinclusive or too vague to operationalize in a democratic regulatory system. Entity-based definitions may be sufficiently precise to operationalize, but they are ultimately uninformative about the source of systemic risk. Moreover, both activity-based and entity-based definitions are static and may fail to capture new forms of shadow banking that use financial innovation to generate systemic risk. Instruments-based definitions may fare better in connection with systemic risk, and if carefully crafted, can adapt to financial innovation. However, they tend to be overinclusive, which brings us back to the operationalization problem. The best way to define shadow banking is, therefore, a combination of the three approaches, with a special focus on the instruments.

Systemic risk stems from the promise of liquidity against long-term, risky investments. There are

not many instruments making such promises credible. These instruments can be characterized as collateral, namely assets that may be liquidated to make good on the promise if the borrower defaults. Liquidity promises are credible if the collateral backing them is liquid, too, implying that the collateral can be turned into cash immediately without losing much of its value.

Banking adds another dimension to the liquidity of collateral, which is leverage. Because banks profit from transforming debts (long into short, safe into risky), they tend to have as much debt, or leverage, as possible. Banks can leverage more than any other economic actor because they rely on various liquidity puts – from other banks, and ultimately, from the central bank. However, leverage is a multiplier of losses as well as of gains, as a result of which banks are more fragile than other economic actors. In the absence of regulation, the market liquidity of assets increases the leverage possibilities of banks (funding liquidity), until the asset price bubble bursts and both market and funding liquidity turns in the other direction. Liquidity and leverage are, therefore, the defining features of banking, both official and shadow (Brunnermeier and Pedersen 2009; Adrian and Shin 2010).

Nabilou and Paccès (2017) define banking as the business of leveraging on collateral to support liquidity promises. When this is not subject to the regulation of liquidity and leverage imposed on banks for the purpose of financial stability, it is shadow banking. For example, demand deposits are banking, but not shadow banking, because they are subject to the liquidity and leverage regulation of banks. Similarly, MMMFs are shadow banking so long as they are not subject to regulatory constraints comparable to those faced by banks. Repos are shadow banking, unless it is carried out by banks whose operation is curtailed by liquidity and leverage regulations. Derivatives were, and still are, a form of shadow banking because they support leveraged liquidity promises, although these are not obvious. A marked-to-market derivative, which is used extensively in shadow banking operations, is effectively an overnight promise to pay the margin call. Because the liquidity and the leverage of derivatives are not

regulated as such, but only indirectly when derivatives are entered into by banks or other systemically important institutions, derivatives markets are still the realm of shadow banking.

This instrument-based approach has several advantages. First, the definition includes all – past, present and future – activities giving rise to systemic risk, because it does not rely on particular markets. Rather, this definition relies on the core instruments of banking at all times: liquidity and leverage. Second, this definition is functional, but not as vague as a functional activity-based definition. Because financial regulation can embed ex-ante the instruments of liquidity and leverage, it can also confer upon a regulatory agency the mandate to regulate them across the board, without creating legitimacy concerns. Third, the definition is not linked to any particular entity. Unfortunately, this is also a limitation of this approach. Recently, a number of techniques to monitor liquidity and leverage have been identified in economics (Brunnermeier and Krishnamurthy 2014). All these overlook that effective reporting obligations can only be legally established on specific entities. You cannot regulate something you cannot measure (Pozsar 2014). Similarly, you cannot measure something you do not know of. For this reason, policymakers should rely on entity-based approaches, too, albeit guided by instrument-based criteria to identify the right entities and adapt this identification with time (Nabilou and Paccès 2017).

The Economic Rationale of Shadow Banking

To cope with systemic risk, it might be tempting to ban shadow banking altogether. This would not be a good idea. First, a prohibition will probably not be effective. Because shadow banking caters to a structural demand for safe assets, a ban would not likely be sufficient to deter the private creation of money-like liabilities; it would only marginally increase the cost of accepting them. Second, even if one could prohibit shadow banking, this would not be efficient. Arguably, a limited amount of shadow banking is welfare

increasing, which turns the policy question into how regulation can induce the optimal amount of shadow banking.

Shadow banking plays an important role in contemporary finance. As traditional banking, it channels credit to the real economy. The comparison of the assets held by shadow banks with those of the official banking sector reveals that, after a short dip in the aftermath of the global financial crisis, the shadow banking system has been growing at the expenses of traditional banking (IMF 2014). The growth of shadow banking is driven by supply-side as well as demand-side factors.

On the supply-side, shadow banking relies on financial markets for productive efficiency. Shadow banking has managed to replicate the banking functions at a lower cost (Mehrling et al. 2013). Liquidity puts and other explicit or implicit guarantees by the banks sponsoring shadow banking replaced the government safety net. Moreover, shadow banking enables regulatory arbitrage. Capital arbitrage plays a major role given the adverse impact of capital regulation on the profitability of banking. In the past, the banking industry used off-balance-sheet structures to mitigate this impact and perform shadow banking activities. The new capital adequacy requirements established after the Global Financial Crisis (GFC) have placed constraints on the off-balance-sheet operations of banks. However, by increasing the cost of doing banking within the regulatory perimeter, as opposed to shadow banking, the new rules have made regulatory arbitrage even more attractive.

On the demand side, the growth of the shadow banking system is attributable to several macroeconomic developments around the world, which created room for new markets (Pozsar 2015). The savings glut starting from 2003, especially from China and the Middle-East, lead to a sizeable demand for safe assets where those savings could be safely invested. This shift of the demand for safe assets, however, happened in a time when the supply of such assets was diminishing. In that period, particularly in the US, a considerable amount of government debt was retired. This shortage of safe assets prompted the private sector to create such assets, at a profit. In addition to the

savings glut, the rise of professional asset management (mutual funds and pension funds) also generated a demand for safe assets for the optimal management of institutional investors' cash balances. Since deposit insurance throughout the globe is capped at amounts too low for large cash pools, turning to traditional bank liabilities is not an option for institutional investors.

Banks could cater to this demand for safe assets through a very old financial instrument, the repo. Thanks to overcollateralization and the short maturity, the repo provides an efficient substitute for demand deposits. Over-collateralization is realized through a so-called haircut, or margin. The haircut is the proportion of the collateral that the borrower has to own, i.e., the equity/debt ratio (the reciprocal of leverage ratio). Haircuts are the lender's margin of safety. Because the repos' safety does not depend on the amount of the contract, they are suitable for the cash-management needs of institutional investors.

The ability of shadow banking to supply safe assets in response to the rising demand for them is, in principle, efficient for the financial system as well as for the real economy (Caballero and Farhi 2018). Firstly, a shortage of safe assets creates a macroeconomic imbalance where savings exceed investments, which ultimately leads to reduced output and unemployment. Moreover, securitization and Securities Financing Transactions (SFTs), which are at the heart of the shadow banking, are beneficial for the financial markets because they allow for a more efficient use and pricing of financial resources. In sum, by providing alternatives to bank deposits for large investors, shadow banking benefits society.

The key question is, however, the cost of shadow banking for society. This cost can be substantial because of systemic risk. The same mechanism to meet the demand for safe assets by global investors is responsible for the collapse of the financial system when the promise of safety cannot be honored. In economic terms, this means that safe assets are overproduced due to a negative externality. A negative externality means that the social cost of shadow banking is higher than the private cost. Similar to banks, the case for regulating shadow banking stems from

the circumstance that shadow-banking crises impose negative externalities on the rest of the system.

Efficient Regulation of Shadow Banking

The negative externalities of shadow banking are the cost of a financial crisis. A financial crisis occurs because there are runs. Runs are systemic when the insolvency concerns affect banking as a whole, not the idiosyncratic features of one or more institutions. A perception of systemic insolvency can happen because of the interconnectedness between the banks (credit channel of contagion) or because all banks are invested in the same classes of assets and their value suddenly becomes unclear (market channel of contagion).

Shadow banks can credibly promise to convert their short-term liabilities into money by investing their funds in financial assets, which are marketable. Under certain conditions, specified by risk models, these assets can be liquidated safely and deliver the funds necessary to honor the liabilities. One of these conditions is the haircut that intermediaries have to maintain to make good on their liquidity promise in every conceivable state of the world (Geanakoplos 2014). Importantly, when the asset is considered sufficiently liquid, the haircut can be zero – i.e., the collateral itself is sufficient to back the liquidity promise. Moreover, shadow banking often relies on a liquidity put by banks for the very unlikely situation in which the safety conditions do not hold true. Asset safety is based on statistical models that can be proved wrong. When this is the case, liabilities such as repos, as well as the assets backing them, are no longer considered safe. A run on shadow banking ensues. This can spread to the more traditional banking system simply by way of activating the above-mentioned liquidity puts.

A run on shadow banking (Gorton and Metrick 2012) seeks to recreate the safety of the assets backing the shadow bank liabilities by imposing higher haircuts for refinancing. This is problematic because, if the system does not have enough equity to meet the margin call, the price of the collateral will crash. This, in turn, will lead to

increasing haircuts making more financial intermediaries insolvent. However, this is not the only way in which a run can occur on shadow banking. A withdrawal from shadow banking can resemble a more “classic” bank run in two situations. First, the collateral may suddenly become unacceptable (i.e., haircut equal to 100%) and no refinancing be offered. Second, shadow banking liabilities are not always guaranteed by what we would call proper collateral in legal terms. For instance, like demand deposits, MMMF shares are not collateralized. In addition, banks issue other short-term wholesale liabilities, such as commercial paper, which may or may not be collateralized. All of these liabilities are susceptible to runs, too.

The law and economics debate on shadow banking rightly focuses on collateral. Collateral is a distinctive feature of banking – both traditional and shadow – if understood in economic, not legal terms. In economic terms, the assets backing a liquidity promise are collateral because they can be sold in deep markets. Whether lenders can seize them to get their money back is of secondary importance. Shadow banking promises money against securities deemed safe according to the prevailing risk models. Upon materialization of tail risk undermining this perceived safety, a collateral crisis ensues, triggering withdrawals from all sorts of lending, whether or not explicitly collateralized. In the presence of large withdrawals from shadow banking, asset prices go down because the agents with leveraged long positions lose wealth and must sell, whereas new agents cannot leverage as much as to absorb the forced sales. Haircuts are a measure of leverage on specific assets, but as we are speaking about banking, leverage implies liquidity and vice versa. When asset prices crash because of withdrawals from the shadow banking system, market liquidity and funding liquidity shrink simultaneously (Brunnermeier and Pedersen 2009).

A run on shadow banking can only be stopped by a central bank credible enough to recreate the perception of safety that was lost. Showing willingness to buy any quantity of the distressed assets at a given price, the central bank effectively

sets an upper limit on haircuts and, by stabilizing the price of the assets being levered upon, stops a financial crisis (Minsky 1986).

Unfortunately, by stopping a financial crisis, the central bank suspends market discipline, too (Pacces 2013). Assets purchased by the central bank cannot be worth less than what the central bank is willing to pay for them. They become “safe” again precisely for this reason. The expectation of such central bank intervention fuels moral hazard. With moral hazard in place, the negative externalities of shadow banking are exacerbated. The overproduction of safe assets by the private sector, which characterizes shadow banking, would be an even bigger problem if central banks guaranteed the safety of collateral at no cost.

To address this problem, commentators have proposed to charge for the prospective liquidity insurance by the central bank. To operationalize this levy, access to collateral for short-term funding should be restricted. For instance, collateralized borrowing could be reserved to a special class of financial institutions, which would be regulated, and pay for insurance, as banks do for deposit insurance (Gorton and Metrick 2010). Alternatively, the levy could be charged as a condition for collateral to enjoy the bankruptcy law privileges that make it attractive for backing short-term liabilities (Perotti 2013). Collateral in repos and marked-to-market derivatives can be seized immediately in case of default, by way of exception to the bankruptcy rules. Charging for the use of bankruptcy-exempt collateral is effectively a Pigovian tax to correct the externality, aiming to make shadow banks bear ex-ante the social cost of illiquidity.

Approaches based on liquidity insurance have the following shortcomings. First, it would be overly difficult to price this insurance accurately. The unavoidable intervention by central banks in collateral crisis makes liquidity a public good (Heremans and Pacces 2011). Setting the price of public goods is always difficult, but pricing a liquidity put can be a daunting task. To avoid moral hazard, the price of insurance should be risk-based. However, the risk of illiquidity is systemic, which is difficult to define, let alone to

measure. Despite the efforts by authoritative economists to measure systemic risk, this measurement can never be precise. Because illiquidity stems from the failure of credit risk models, there is no reason why systemic risk models, however sophisticated, should be infallible.

As second problem with charging for the central bank’s liquidity put is time inconsistency. The threat to withhold the liquidity put from those who have not paid the insurance premium is not credible. As soon as the collateral becomes systemic, the central bank’s liquidity put is the tool of last resort to avoid financial collapse.

Finally, the economic definition of collateral is much broader than the legal definition. A liquidity tax can only be imposed on entities or instruments we know of. However, how shadow banking will look like in the future is not known. In the future, shadow banking may not rely explicitly on collateral as we know it but still produce money-like liabilities in such proportions as to claim the liquidity put by the central bank during a financial crisis.

According to Nabilou and Pacces (2017), quantity regulation is preferable to a Pigovian tax to cope with the externalities of shadow banking because the social cost – the individual contribution to systemic risk by shadow banks – is difficult to estimate. Moreover, quantity regulation is relatively easy to implement via a single policy variable, which is leverage. Finally, leverage is a straightforward indicator to which regulation can be immediately linked (e.g., as minimum haircut regulation), without need to rely on a complex, thus fallacious, model of systemic risk. Leverage is a necessary condition for shadow banking, so the latter can be identified and cut down in size through the former. Following the economic literature advocating monitoring and curbing leverage on the assets that can be pledged as collateral (Geanakoplos and Pedersen 2014), shadow banking should be regulated indirectly, by capping the admissible levels of leverage on these assets. Regulation can constrain leverage at the asset level by setting up minimum requirements in terms of collateral ownership by the borrower, that is to say, minimum haircut regulations.

As argued by Nabilou and Paccès (2017), minimum haircuts should be established on every debt contract generating short-term, money-like liabilities. This is necessary but not sufficient to curb shadow banking. Short-term liabilities could be issued without explicit reference to collateral. Therefore, leverage should be monitored and restricted at the level of the entities making such promises, too. This is not as difficult as it looks. In practice, liquidity promises by shadow banks are credible only if they are backed by marketable assets or a robust liquidity put. Banks are able to make unsecured promises because they rely on a web of credit and liquidity puts from the public sector. For this reason, banks' capital is directly regulated. Such a regulation does extend to shadow banking in as much as the latter is sponsored by banks and such sponsorships count towards the leverage contains imposed on banks.

An indirect regulation of shadow banking based on restricting the channels for money creation has the advantage to cope with financial innovation. These channels are defined broadly enough to capture different ways in which shadow banking may play out in the future and in different jurisdictions. The latter circumstance is very useful for international cooperation, which is essential to regulate shadow banking effectively. At the same time, asset leverage and bank leverage restrictions are sufficiently specific concepts to embed into legislation. This overcomes the legitimacy concerns that could arise if these restrictions were to be established exclusively by regulatory agencies.

Two challenges remain, however. The first challenge is to set the minimum haircuts at the right level, bearing in mind that excessive curbs on (shadow) banking undermine efficiency. The second challenge is to adjust these regulations over time. Dealing with the first problem requires statistical models, similar to those necessary to identify the optimal restrictions for banking institutions. Asset-based models of risk assessment, however, are much simpler than the models used to measure systemic risk. Setting conservative haircuts only requires identifying the worst-case price scenario for each class of assets.

The second problem is more difficult to deal with. On the one hand, new classes of assets may be used for leverage. On the other hand, the conservative haircuts will have to be adapted to new circumstances, in one direction or another. The adaptation problem depends on the same reason why, in the end, all preventative regulations for minimizing systemic risk – including shadow banking regulation – will fail and require crisis management. This is a general problem in the pursuit of financial stability as a policy goal. Arguably, the regulation of leverage, particularly at the asset level, fares better than alternative approaches to regulate shadow banking. However, the efficient regulation of shadow banking, as of any other source of systemic risk, calls upon financial regulators to exercise some discretion in order to adapt to unforeseen circumstances.

Conclusion and Future Research

This essay discusses the economics of shadow banking and the case for its regulation. An important challenge in addressing shadow banking is to define it. All the main approaches to defining shadow banking have shortcomings. An instrument-based approach seems to be preferable to cope with systemic risk in the presence of financial innovation. However, an effective instrument-based regulation presupposes that the entities having access to the relevant instruments are subject to reporting obligations.

Shadow banking is beneficial for society because it caters to a demand for safe assets. However, because of negative externalities, shadow banking is overproduced. Quantity regulation is preferable to a Pigovian tax to cope with the externalities of shadow banking because uncertainty makes any measure of systemic risk imprecise. Regulation should limit the leverage of shadow banking by way of minimum haircuts regulation on assets being used as collateral. Moreover, shadow banking should be regulated indirectly, through the capital regulation of banks providing explicit or implicit liquidity puts.

The implementation of an optimal regulation of shadow banking faces two important challenges.

First, it is difficult to identify the optimal levels of asset and institutional leverage. Second, it is even more difficult to adapt these levels to new circumstances. These challenges, however, apply as well to banking in general. A way to address them may be to provide financial regulators with some discretion under incentive-compatible regulatory governance. This is an interesting avenue for future research.

Shadow Economy

Friedrich Schneider

Department of Economics, Johannes Kepler University of Linz, Linz-Auhof, Austria

Abstract

In this paper the main focus lies on the shadow economy. The most influential factors on the shadow economy are tax policies and state regulation. The size of the shadow economy was decreasing over 1999 to 2007 from 34.0% to 31.2% for 161 countries (unweighted average).

Keywords

Shadow economy; Tax morale; Tax pressure; State regulation; Labor market

Synonyms

[Black economy](#); [Informal economy](#); [Unofficial economy](#)

Definition of the Shadow Economy

Up to today, authors trying to measure the shadow economy face the difficulty of a precise definition of the shadow economy. According to one commonly used definition, it comprises all currently unregistered economic activities that contribute to the officially calculated gross national product. Do-it-yourself activities are not included. This definition is used, e.g., by Feige (1989, 1994), Schneider (1994a, 2003, 2005), and Frey and Pommerehne (1984). Smith (1994, p. 18) defines it as “market-based production of goods and services, whether legal or illegal, that escapes detection in the official estimates of GDP.” Put differently, one of the broadest definitions is: “...those economic activities and the income derived from them that circumvent or otherwise avoid government regulation, taxation or observation.” This definition is taken from Dell’Anno (2003), Dell’Anno and Schneider (2004), and Feige (1989).

In this entry the following more narrow definition of the shadow economy is used. The shadow economy includes all market-based legal production of goods and services that are deliberately concealed from public authorities for the following reasons:

1. To avoid payment of income, value added, or other taxes
2. To avoid payment of social security contributions
3. To avoid having to meet certain legal labor market standards, such as minimum wages, maximum working hours, safety standards, etc.

4. To avoid complying with certain administrative obligations, such as completing statistical questionnaires or other administrative forms

Thus, I will not deal with typically illegal underground economic activities that fit the characteristics of classical crimes like burglary, robbery, drug dealing, etc. I also exclude the informal household economy which consists of all household services and production.

Introduction

Fighting tax evasion and the shadow economy have been important policy goals in OECD countries during recent decades. In order to do this, one should have knowledge about the size and development of the shadow economy as well as the reasons why people are engaged in shadow economy activities. This is the content of this entry. Tax evasion is not considered in order to keep the subject of this entry tractable and because too many additional aspects would be involved. Also tax morale or experimental studies on tax compliance are beyond the scope of this entry.

My entry is organized as follows: section “[Some Theoretical Considerations About the Shadow Economy](#)” presents theoretical considerations about the measurement of the shadow economy and discusses also the main factors determining its size. In section “[Size of the Shadow Economies all Over the World](#)” the empirical results of the size and development of the shadow economy are discussed. Finally section “[Conclusions](#)” concludes.

Some Theoretical Considerations About the Shadow Economy**Measuring the Shadow Economy**

The definition of the shadow economy plays an important role in assessing its size. By having a clear definition, a number of ambiguities and controversies can be avoided. In general, there are two types of shadow economic activities: illicit employment and the in the household produced

goods and services mostly consumed within the household. The following analysis focuses on both types but tries to exclude illegal activities such as drug production, crime, and human trafficking. The in the household produced goods and services, e.g., schooling and childcare are not part of this analysis. Thus, it only focuses on productive economic activities that would normally be included in the national accounts but which remain underground due to tax or regulatory burdens. With this definition the problem of having classical crime activities included could be avoided, because neither the MIMIC procedure nor the currency demand approach captures these activities: e.g., drug dealing is independent of increasing taxes, especially as the included causal variables are not linked (or causal) to classical crime activities. See, e.g., Thomas (1992), Kazemir (2005a, b), and Schneider (2005). Although such legal activities contribute to the country's value added, they are not captured in the national accounts because they are produced in illicit ways (e.g., by people without proper qualification or without a master craftsman's certificate). From the economic and social perspective, soft forms of illicit employment, such as moonlighting (e.g., construction work in private homes), and its contribution to aggregate value added can be assessed rather positively.

Although the issue of the shadow economy has been investigated for a long time, the discussion regarding the "appropriate" methodology to assess its scope has not come to an end yet. For the strengths and weaknesses of the various methods see, e.g., Dell'Anno and Schneider (2009), Feige (1989), and Feld and Larsen (2005). There are three methods of assessment:

- (1) Direct procedures at a micro level that aim at determining the size of the shadow economy at one particular point in time. An example is the survey method
- (2) Indirect procedures that make use of macroeconomic indicators in order to proxy the development of the shadow economy over time
- (3) Statistical models that use statistical tools to estimate the shadow economy as an "unobserved" variable

Today in many cases the estimation of the shadow economy is based on a combination of the MIMIC procedure and on the currency demand method or the use of only the currency demand method. These methods are presented in detail in Schneider (1994a, b, c, 2005, 2011, 2014), Schneider and Williams (2013), Feld and Schneider (2010), and Schneider and Enste (2000, 2002, 2006). The MIMIC procedure assumes that the shadow economy remains an unobserved phenomenon (latent variable) which can be estimated using quantitatively measurable causes of illicit employment, e.g., tax burden and regulation intensity, and indicators reflecting illicit activities, e.g., currency demand, official GDP, and official working time. A disadvantage of the MIMIC procedure is the fact that it produces only relative estimates of the size and the development of the shadow economy. Thus, the currency demand method is used to calibrate the relative into absolute estimates (e.g., in percent of GDP) by using two or three absolute values (in percent of GDP) of the size of the shadow economy. This indirect approach is based on the assumption that cash is used to make transactions within the shadow economy. By using this method one econometrically estimates a currency demand function including independent variables like tax burden, regulation, etc. which "drive" the shadow economy. This equation is used to make simulations of the amount of money that would be necessary to generate the official GDP. This amount is then compared with the actual money demand, and the difference is treated as an indicator for the development of the shadow economy. On this basis the calculated difference is multiplied by the velocity of money of the official economy and one gets a value added figure for the shadow economy.

In addition, the size of the shadow economy is estimated by using survey methods (Feld and Larsen (2005, 2008, 2009). In order to minimize the number of respondents dishonestly replying or totally declining answers to the sensitive questions, structured interviews are undertaken (usually face-to-face) in which the respondents are slowly getting accustomed to the main purpose of the survey. Like it is done by the contingent valuation method (CVM) in environmental

economics (Kopp et al. 1997), a first part of the questionnaire aims at shaping respondents’ perception as to the issue at hand. In a second part, questions about respondents’ activities in the shadow economy are asked, and the third part contains the usual sociodemographic questions.

In addition to the studies by Merz and Wolff (1993), Feld and Larsen (2005, 2008, 2009), Haigner et al. (2013), and Enste and Schneider (2006) for Germany, the survey method has been applied in the Nordic countries and Great Britain (Isachsen and Strøm 1985; Pedersen 2003) as well as in the Netherlands (van Eck and Kazemier 1988; Kazemier 2006). While the questionnaires underlying these studies are broadly comparable in design, recent attempts by the European Union to provide survey results for all EU member states run into difficulties regarding comparability (Renooy et al. 2004; European Commission 2007); the wording of the questionnaires becomes

more and more cumbersome depending on the culture of different countries with respect to the underground economy.

To summarize: Although each method has its strength and weaknesses and biases in the estimates of the shadow economy almost certainly prevail, no better data are currently available. Clearly, there can be no exact measure of the size of the shadow economy, and estimates differ widely with an error margin of $\pm 15\%$. These days, macro estimates derived from the MIMIC model, the currency demand method, or the electricity approach are seen as upper bound estimates, while micro (survey) estimates are seen as lower bound estimates.

The Main Causes Determining the Shadow Economy

Table 1 presents an overview of the most important determinants influencing the shadow

Shadow Economy, Table 1 The main causes determining the shadow economy

Causal variable	Theoretical reasoning	References
Tax and social security contribution burdens	The distortion of the overall tax burden affects labor-leisure choices and may stimulate labor supply in the shadow economy. The bigger the difference between the total labor cost in the official economy and after-tax earnings (from work), the greater is the incentive to reduce the tax wedge and to work in the shadow economy. This tax wedge depends on social security burden/payments and the overall tax burden, making them to key determinants for the existence of the shadow economy	E.g., Thomas (1992), Johnson, Kaufmann, and Zoido-Lobaton (1998a, b), Giles (1999), Tanzi (1999), Schneider (2003, 2005), Dell’Anno (2007), Dell’Anno et al. (2007), Buehn and Schneider (2012)
Quality of institutions	The quality of public institutions is another key factor for the development of the informal sector. Especially the efficient and discretionary application of the tax code and regulations by the government plays a crucial role in the decision to work underground, even more important than the actual burden of taxes and regulations. In particular, a bureaucracy with highly corrupt government officials seems to be associated with larger unofficial activity, while a good rule of law by securing property rights and contract enforceability increases the benefits of being formal. A certain level of taxation, mostly spent in productive public services, characterizes efficient policies. In fact, the production in the formal sector benefits from a higher provision of productive public services and is negatively affected by taxation, while the shadow economy reacts in the opposite way. An informal sector developing as a consequence of the failure of political institutions in promoting an efficient market economy and entrepreneurs going underground, as there	E.g., Johnson et al. (1998a, b), Friedman et al. (2000), Dreher and Schneider (2009), Dreher et al. (2009), Schneider (2010), Buehn and Schneider (2012), Teobaldelli (2011), Teobaldelli and Schneider (2012), Amendola and Dell’Anno (2010), Losby et al. (2002), Schneider and Williams (2013)

(continued)

Shadow Economy, Table 1 (continued)

Causal variable	Theoretical reasoning	References
	is an inefficient public goods provision, may reduce if institutions can be strengthened and fiscal policy gets closer to the median voter's preferences	
Regulations	Regulations, for example, labor market regulations or trade barriers, are another important factor that reduces the freedom (of choice) for individuals in the official economy. They lead to a substantial increase in labor costs in the official economy and thus provide another incentive to work in the shadow economy; countries that are more heavily regulated tend to have a higher share of the shadow economy in total GDP. Especially the enforcement and not the overall extent of regulation – mostly not enforced – is the key factor for the burden levied on firms and individuals, making them operate in the shadow economy	E.g., Johnson, Kaufmann, and Shleifer (1997), Johnson, Kaufmann, and Zoido-Lobaton (1998b), Friedman et al. (2000), Kucera and Roncolato (2008), Schneider (2011)
Public sector services	An increase of the shadow economy may lead to fewer state revenues, which in turn reduce the quality and quantity of publicly provided goods and services. Ultimately, this may lead to increasing tax rates for firms and individuals, although the deterioration in the quality of the public goods (such as the public infrastructure) and of the administration continues. The consequence is an even stronger incentive to participate in the shadow economy. Countries with higher tax revenues achieved by lower tax rates, fewer laws and regulations, a better rule of law, and lower corruption levels should thus have smaller shadow economies	E.g., Johnson, Kaufmann, and Zoido-Lobaton (1998a, b), Feld and Schneider (2010)
Tax morale	The efficiency of the public sector also has an indirect effect on the size of the shadow economy because it affects tax morale. Tax compliance is driven by a psychological tax contract that entails rights and obligations from taxpayers and citizens on the one hand but also from the state and its tax authorities on the other hand. Taxpayers are more heavily inclined to pay their taxes honestly if they get valuable public services in exchange. However, taxpayers are honest even in cases when the benefit principle of taxation does not hold, i.e., for redistributive policies, if such political decisions follow fair procedures. The treatment of taxpayers by the tax authority also plays a role. If taxpayers are treated like partners in a (tax) contract instead of subordinates in a hierarchical relationship, taxpayers will stick to their obligations of the psychological tax contract more easily. Hence, (better) tax morale and (stronger) social norms may reduce the probability of individuals to work underground	E.g., Feld and Frey (2007), Kirchler (2007), Torgler and Schneider (2009), Feld and Larsen (2005, 2009), Feld and Schneider (2010)
Deterrence	Despite the strong focus on deterrence in policies fighting the shadow economy and the unambiguous insights of the traditional economic theory of tax noncompliance, surprisingly little is known about the effects of deterrence from empirical studies. This is due to the fact that data on the legal background and the frequency of audits are not available on an international basis; even for OECD countries such data is difficult to collect. Either is the legal background quite complicated differentiating fines and punishment according to the severity of the offense	E.g., Andreoni et al. (1998), Pedersen (2003), Feld and Larsen (2005, 2009), Feld and Schneider (2010)

(continued)

Shadow Economy, Table 1 (continued)

Causal variable	Theoretical reasoning	References
	and the true income of the noncomplier or tax authorities do not reveal how intensively auditing is taking place. The little empirical survey evidence available demonstrates that fines and punishment do not exert a negative influence on the shadow economy, while the subjectively perceived risk of detection does. However, the results are often weak and Granger causality tests show that the size of the shadow economy can impact deterrence instead of deterrence reducing the shadow economy	
Agricultural sector	The importance of agriculture in the economy is included, since many studies endorse the idea that informal work is concentrated in highly segmented sectors, with clear prevalence for the agricultural and related sectors. One of the most important reasons for this is the minimum enforcement capacity of governments prevalent in rural areas. The importance of agriculture is measured as the share of agriculture as percentage of GDP. The larger the agricultural sector, the larger the expected size of the shadow economy, <i>ceteris paribus</i>	E.g., Vuletin (2008), De la Roca et al. (2002), Greenidge et al. (2005), Mootoo et al. (2002), Amendola and Dell'Anno (2010), Losby et al. (2002)
Development of the official economy	The development of the official economy is another key factor of the shadow economy. The higher (lower) the unemployment quota (GDP growth), the higher is the incentive to work in the shadow economy, <i>ceteris paribus</i>	Schneider and Williams (2013) Feld and Schneider (2010)
Self-employment	The higher self-employment is, the more activities can be done in the shadow economy, <i>ceteris paribus</i>	Schneider and Williams (2013) Feld and Schneider (2010)

economy. Due to space reasons, there is no detailed discussion of the various determinants/causes of the shadow economy.

Size of the Shadow Economies all Over the World

The figures below are taken from Schneider et al. (2010). The econometric MIMIC estimation results are not shown here due to space reasons; see, e.g., Schneider et al. (2010). Figure 1 shows the average size of the shadow economy of 162 countries over 1999–2007. In Tables 2 and 3 the average informality (unweighted and weighted) in different regions is shown using the regions defined by the World Bank. The World Bank distinguishes 8 world regions which are East Asia and Pacific, Europe and Central Asia, Latin America and the Caribbean, Middle East and North Africa, High Income OECD, Other High

Income, South Asia, and Sub-Saharan Africa. If we consider first Table 2 where the average informality (unweighted) is shown, we see that Latin America and the Caribbean have the highest value of the shadow economies of 41.1%, followed by Sub-Saharan Africa of 40.2%, and then followed by Europe and Central Asia of 38.9%. The lowest has the High Income OECD countries with 17.1%. If we consider the average informality of the shadow economies of these regions weighted by total GDP in 2005, Sub-Saharan Africa has the highest with 37.6%, followed by Europe and Central Asia with 36.4%, and Latin America and the Caribbean with 34.7%. The lowest again has the High Income OECD with 13.4%. If one considers the world mean weighted and unweighted, one sees that if one uses the unweighted measures, the mean is 33.0% over the periods 1999–2007. If we consider the world with weighted informality measures, the shadow economy takes “only” a value of 17.1% over the period 1999–2007.

Shadow Economy,

Fig. 2 Size and development of the shadow economy of various countries' groups (weighted averages (!); in percent of official total GDP of the respective Country Group) (Source: Schneider et al. 2010)

Weighting the values makes a considerable difference.

One general result of the size and development of the shadow economies worldwide is that there is an overall reduction in the size. In Fig. 2 the size

and development of the shadow economy of various countries' groups (weighted averages by the official GDP of 2005) over 1999, 2003, and 2007 are shown. One clearly realizes that for all countries' groups (25 OECD countries, 116 developing

countries, 25 transition countries) I observe a decrease in the size of the shadow economy. The average size of the shadow economies of the 162 countries was 34.0% of official GDP (unweighted measure!) in 1999 and decreased to 31.2% of official GDP in 2007. This is a decrease of almost 3.0 percentage points over 9 years. Growth of the official economy with reduced (increased) unemployment (employment) seems to be the most efficient mean to reduce the shadow economy.

Conclusions

In this entry some of the most recent developments in research on the shadow economy in highly developed OECD, developing, and transition countries are shown. The discussion of the recent literature shows that economic opportunities for employees, the overall situation on the labor market, not least unemployment are crucial for an understanding of the dynamics of the shadow economy. Individuals look for ways to improve their economic situation and thus contribute productively to aggregate income of a country. This holds regardless of their being active in the official or the unofficial economy.

A last question remaining is: What type of policy conclusions can I draw? One conclusion may be that – besides the indirect tax and personal income tax burden, which the government can directly influence by policy actions – self-employment and unemployment are two very important driving forces of the shadow economy. Unemployment may be controllable by the government through economic policy in a traditional Keynesian sense; alternatively, the government can try to improve the country's competitiveness to increase foreign demand. The impact of self-employment on the shadow economy is less or only partly controllable by the government and may be ambiguous from a welfare perspective. A government can deregulate the economy or incentivize "to be your own entrepreneur," which would make self-employment easier, potentially reducing unemployment and positively

contributing to efforts in controlling the size of the shadow economy. Such actions however need to be accompanied with a strengthening of institutions and tax morale to reduce the probability that self-employed shift reasonable proportions of their economic activities into the shadow economy, which, if it happened, made government policies incentivizing self-employment less effective. This entry clearly shows that a reduction of the shadow economy can be achieved using various channels the government can influence. The main challenge still is to bring shadow economic activities into the official economy in a way that goods and services previously produced in the shadow economy are still produced and provided but in the official economy. Only then, the government gets additional taxes and social security contributions.

Finally, if I ask what we know about the shadow economy, I clearly realize that we have some knowledge about the size and development of the shadow economy. What we do not know are the exact motives, why people work in the shadow economy, and what is their relation and feeling if a government undertakes reforms in order to bring them back into the official economy. Hence, much more micro studies are needed to obtain a more detailed knowledge about people's motivation to work either in the shadow economy and/or in the official one.

Definition

The Shapley value (Shapley 1953) probably is the most eminent (single-valued) solution concept for cooperative games with transferable utility (TU games)¹. A **(TU) game** is a pair (N, v) consisting of a nonempty and finite set of players N and a **coalition function** $v \in \mathbb{V}(N) := \{f : 2N \rightarrow \mathbb{R} | f(\emptyset) = 0\}$. Subsets of the player set are called **coalitions**. The coalition function assigns a **worth** $v(S)$ to any coalition S , which indicates what the players in S can achieve by cooperation. A (single-valued) **solution concept** φ on N assigns to any game (N, v) a payoff vector $\varphi(N, v) \in \mathbb{R}^N$, where $\varphi_i(N, v)$ denotes the payoff of player i in the game (N, v) .

The Shapley value on the player set N is defined as follows: A rank order on N is a bijection $\rho : N \rightarrow \{1, \dots, |N|\}$ with the interpretation that i is the $\rho(i)$ th player in ρ ; $R(N)$ denotes the set of all rank orders. The set of players up to and

¹Peleg and Sudhölter (2007) provide a good introduction to cooperative game theory.

including i in ρ is denoted by $P_i(\rho) = \{j \in N : \rho(j) \leq \rho(i)\}$. The marginal contribution of i in the game v in ρ is defined as $MC_i^v(\rho) := v(K_i(\sigma)) - v(K_i(\sigma) \setminus \{i\})$. Finally, the Shapley value, Sh , is the average marginal contribution over all rank orders, i.e.,

$$Sh_i(N, v) := \frac{1}{|R(N)|} \cdot \sum_{\rho \in R(N)} MC_i^v(\rho) \text{ for all } v \in \mathbb{V}(N) \text{ and } i \in N.$$

The marginal contribution $MC_i^v(\rho)$ measures the productivity of player i with respect to the coalition of his predecessors in ρ . By taking the average over all rank orders, the Shapley value can be viewed as an indicator of the players' productivity in a game.

Properties and Characterization

The Shapley value has a lot of properties worth mentioning, among them efficiency, symmetry, and strong monotonicity. A solution concept φ on N is called **efficient** if $\sum_{i \in N} \varphi_i(v) = v(N)$ for all $v \in \mathbb{V}(N)$. Efficiency indicates that all players from N first cooperate in order to create the worth of $v(N)$ and then this worth is distributed among them without losses (e.g., bargaining costs) or gains (e.g., subsidies). Players $i, j \in N$ are called symmetric in $v \in \mathbb{V}(N)$, if $v(S \cup \{i\}) - v(S) = v(S \cup \{j\}) - v(S)$ for all $S \subseteq N \setminus \{i, j\}$, i.e., symmetric players are equally productive. A solution concept φ on N is called **symmetric** if $\varphi_i(v) = \varphi_j(v)$ for all $v \in \mathbb{V}(N)$ and $i, j \in N$ such that i and j are symmetric in v , i.e., symmetry requires that players who are equally productive obtain the same payoffs. A solution concept φ on N is called **strongly monotonic** if $\varphi_i(v) \geq \varphi_i(w)$ for all $v, w \in \mathbb{V}(N)$ and $i \in N$ such that $v(S \cup \{i\}) - v(S) \geq w(S \cup \{i\}) - w(S)$ for all $S \subseteq N \setminus \{i\}$. Strong monotonicity requires that a player's payoff does not decrease when his productivity measured by marginal contributions does not decrease, irrespective of what happens to other players' productivity. This implies that a player's payoff only depends on his own productivity.

The Shapley value not only satisfies these three properties, but it is already characterized by them—the Shapley value is the unique solution concept that meets efficiency, symmetry, and strong monotonicity (Young 1985). This supports the view that the Shapley value is *the* measure of the players' productivities in a TU game.

Weighted Voting Games and the Shapley-Shubik (Power) Index

A game (N, v) is called **simple** if $v(S) \in \{0, 1\}$ for $S \subseteq N$; it is called **monotonic** if $v(S) \leq v(T)$ for all $S, T \subseteq N$ such that $S \subseteq T$. Important examples of simple and monotonic games are the so-called weighted voting games. A weighted voting game (N, v) is given by a quota $q > 0$ and weights of the players $w_i > 0, i \in N$ as follows. For all $S \subseteq N$, we have $v(S) = 1$ if $\sum_{i \in S} w_i > q$ and $v(S) = 0$ if $\sum_{i \in S} w_i \leq q$. The Shapley value applied to voting games is also known as the **Shapley-Shubik (power) index** (Shapley and Shubik 1954). For these games, the calculation of the Shapley value can be simplified: A coalition $S \subseteq N \setminus \{i\}$ is called a swing for player $i \in N$ in v if $v(S \cup \{i\}) = 1$ and $v(S) = 0$, i.e., if i turns S into a winning coalition. We then have

$$Sh_i(N, v) = \frac{1}{|N|!} \cdot \sum_{S \subseteq N \setminus \{i\} : S \text{ is a swing for } i} |S|! \cdot (|N| - |S| - 1)!,$$

where $|N|!$ is the number of all rank orders on N and $|S|! \cdot (|N| - |S| - 1)!$ is the number of all rank orders ρ in which player i "enters" coalition S , i.e., $P_i(\rho) \setminus \{i\} = S$.

Applications in Law and Economics

Most applications of the Shapley value in law and economics used are for cost allocation (see, e.g., Shubik 1962; Roth and Verrecchia 1979) or as a power index. For example, Newman (1981) analyzes the voting power of the Big Eight audit firms in the Accounting Principles Board (APB) and in

the Financial Accounting Standards Board (FASB). Leech (1988) and Casajus et al. (2009) use the Shapley-Shubik index in order to determine the voting power of shareholders in shareholders' meetings.

Spence's idea is that the education level of an applicant serves as a signal to indicate productivity level. The crucial assumption is that people with higher productivity incur lower costs (money, effort) of acquiring education than those with lower productivity. This leads to the fundamental insight that even if education did not contribute anything to work productivity, it can serve as a tool to separate high- from low-ability employees. In 2001, Michael Spence won the Nobel Prize in economic sciences, along with George A. Akerlof and Joseph E. Stiglitz, for their significant contribution on the analysis of markets with asymmetric information.

Definition

A signal is a choice that conveys information about the sender of the signal. When the communicating parties have different goals, the signal to be credible must be costly to fake. When selling a product, for example, the seller of a product can issue a warrantee to signal the quality to the buyer. Signalling takes place in situations of information asymmetry where one party has more information than the other party. In contract theory and economics, signalling models fall under the category of principal-agent models. Here, the “agent” has private information compared to the “principal.”

Abstract

In his seminal paper “Spence (Q J Econ 87(3):355–374, 1973)” introduced a signalling model for the job market. In this model the employer (the principal) is not sure about the ability of the potential employee (the agent).

Signalling

The need for reliable signals results from the problems of communication between parties with different goals. The solicitor for a job, for example, has an incentive to overstate her ability. The buyer of insurance, likewise, has an incentive to misrepresent her risks. Similarly, the seller of a used car has an incentive to overstate the quality of her car, while the buyer is not keen to reveal her reservation price. This is fundamentally different to communication with common goals as, for example, the communication between bridge playing partners. Here, communication is simply

a transfer of information, and the receiver of the message does not need to question its credibility.

For a signal (message) to be credible between adversaries, the signal must be costly to fake. As an example consider a certificate from a massive open online course that was gained by taking an online test. Since taking the test is not fraud resistant and hence passing the test is easy to fake, a certificate gained in this way is usually not accepted as a credible signal for ability.

In contract theory and economics, the term information asymmetry refers to scenarios where one party holds information that the other party does not have, usually represented by principal-agent models. Here, the “agent” has private information in contrast to the “principal” who has information about general statistics. When applying for a job, for example, the applicant is the agent who knows his ability for the job, while the employer, the principle, lacks this information but can usually estimate the likelihood of a candidate being capable. Typically, the agent tries to send a signal about his private information, and the principle has to decide whether this signal is credible.

The formal tools to describe and analyze the strategic scenario of signalling are provided by game theory. The following example is taken from Spence (1973) and illustrates some basic game theoretic terminology by means of a job market model. This model, together with Akerlof’s (1970) model of The Market for Lemons, belongs to the classics of games with information asymmetry. The simplest version is as follows. There are two groups of employees, workers with low or high productivity, say, productivity level 1 (low) or 2 (high). An agent knows his productivity level and applies for a job. If the employer could assess his productivity *ex ante*, she would offer wage 1 in case it is low and 2 if it is high.

Agents in the job market can choose an education level E which is visible. There is a vast literature as to what extent education *causes* high productivity. The problem, in a nutshell, is that wage differences between employees with degrees from prestigious and nonprestigious institutions cannot be entirely attributed to the education itself.

After all, many prestigious universities screen their applicants such that they are already more productive to begin with. In order to keep the model simple, however, assume that education itself does not affect the productivity of the worker (for a more general approach, see Spence 1974, 2001). Assume that the cost of education is, *ceteris paribus*, higher for low-productivity workers, where costs can be money, time, and effort. In particular, assume the cost for low-ability worker of E years of education is E , whereas it is $E/2$ for high-ability workers. Figure 1 is reproduced from Spence (2001) where the lines with a positive slope represent the costs and the bold horizontal lines represent the wages. There are three kinds of equilibria.

1. *Separating equilibria.* The low- and high-ability workers choose different education levels such that the employer can identify the sender of this signal as either “low” or “high.” The high-ability workers choose the education level E^* with $1 < E^* < 2$. This implies a wage level of $2 - E^*/2 > 1$. The low-ability workers choose an education level of 0 with a net wage of 1. Note that the low-ability workers do not have an incentive to imitate the education level of the high-ability workers as their net wage would be $2 - E^* < 1$. In order for these choices to be part of a separating equilibrium, the strategy of the employer must be a best answer to the behavior of the employees. The employer observes the education level E and offers wage 1 if $E < E^*$ or wage 2 if $E \geq E^*$, reflecting her belief about the applicant’s productivity. This belief is confirmed by the behavior of the employees. Assuming $1 < E^* < 2$ implies that there is a continuum of separating equilibria, one for each value of E^* between 1 and 2.
2. *Pooling equilibria.* All workers choose the same education level; in particular consider the case where all workers choose an education level of zero. In the absence of a separating tool, the employer pays a weighted average wage. Pooling equilibria are sustained when the fraction of low-ability workers is sufficiently small such that the effect on average

Signalling, Fig. 1 Costs, wages, and the separating education level in the model of Spence (1973)

wage is not large enough to trigger expensive signalling for the high-ability workers. To be more precise, recall that sending the signal of education E^* is costly with a net wage $2 - E^*/2$. Assume α is the fraction of the low-productivity population. In the absence of a separating equilibrium, there is no way the employer could distinguish productivity ex ante. This implies she would be willing to contract for a wage reflecting the average productivity $\alpha \cdot 1 + (1 - \alpha) \cdot 2$ which simplifies to $2 - \alpha$. For a sufficiently small population of low-productivity workers, α , the average wage paid to the high-ability worker is therefore higher than getting wage 2 with signalling costs $E^*/2$. In particular, the inequality $2 - \alpha > 2 - E^*/2$ can be simplified to $\alpha < E^*/2$. Since E^* is bounded from below by 1, this implies that for $\alpha < 1/2$ there is a pooling equilibrium in which no employee invests in education and employers pay average productivity $2 - \alpha$ as wages. As noted by Spence (2001), this is a “better” equilibrium in the Pareto sense (everybody is better off) than the separating equilibrium. The reason is that education used merely for signalling purposes costs resources without enhancing productivity. Note that zero education is not the only pooling equilibrium. It turns out that there is an $E' > 0$ such that any education level

between 0 and E' can be sustained in a pooling equilibrium (for details, see Spence 1973).

3. *Hybrid equilibria.* In this class of equilibria, one or both types randomize. For example, it is possible to show that the following can arise as equilibrium in the job market model. Low types choose an education level of 0, while the high type randomizes between 0 and a positive education level. In equilibrium, the employer identifies a high-ability worker by observing a positive education level. When the education level is zero, however, her belief that this signal comes from a high-ability worker is a probability derived from updating $1 - \alpha$ following Bayes’ rule. It relates the frequency of observing zero education from a high-ability type to the overall frequency of observing zero education (for details, see, e.g., Fudenberg and Tirole (1991), Chapter 8).

Adverse Selection in Absence of a Separating Signal

Note that $2 - \alpha$ is a very attractive wage for the low-ability worker whose productivity is in fact only 1. It is, however, less attractive to the high-ability worker such that they could have an incentive to leave the labor market (and become, e.g., entrepreneur). This would cause α to increase

such that average wages $2 - \alpha$ would drop even further. This drop, in turn, makes staying in the labor market even less attractive for high-ability workers. In the end, all workers left in the labor market may be of low ability. This phenomenon is usually referred to as the adverse selection problem: a process which attracts the less desirable potential trading partners. Adverse selection is especially relevant to insurance markets. Here, the private information is the risk profile of the policy owner (agent) which is relevant for the insurance premium. Offering insurance without deductible based on average-risk attitude will be unattractive to the low-risk type and attractive to the high-risk type. Consequently, a premium based on average risk will attract more high-risk types leading to a higher average risk and therefore an increase of the insurance premium. This in turn repels the low-risk profiles even more. In the end, only high-risk types may participate in the insurance market. In his paper "The Market for Lemons," Akerlof (1970) used the logic behind this downward spiral to explain why almost new cars sell for so much less than brand new cars. A used car in a bad state is commonly referred to as "lemon" which is private information of the seller, the agent. Buyers cannot distinguish the quality of a used car and are therefore only willing to pay a price representing average quality of the used car market. This implies that owners of good cars have a stronger incentive to keep them which implies a decrease in the average quality of cars for sale. This decrease, in turn, lowers the reservation price of the of sellers - which kicks off the downward spiral of adverse selection processes. In conclusion, Akerlof's Lemons model explains why secondhand cars are, on average, of lower quality than cars not for sale. An almost new car for sale is therefore associated with the large pool of lemons and sells only for the average price of this pool.

Signalling versus Screening and Signals versus Indices

A screening game is closely related to a signalling game. Here, the principal (the uninformed player)

chooses a strategy that induces the agent (informed player) to reveal their type. For example, insurance companies screen customers by offering different policies at different rates. High-risk types will be less likely to favor an insurance contract with deductibles (Stiglitz and Weiss 1990) and thereby revealing their type.

It is helpful to carefully distinguish between indices and signals. According to Spence (1973, 1974, 2001), "indices" are unchangeable attributes over which an individual has no control, e.g., gender, age, race, etc. A signal, however, is a visible attempt to communicate that can be changed by a person. As an example take the Irish car insurance market where males less than 25 years pay more than females of the same age. Here, age and gender are indices that are used for statistical discrimination, i.e., the practice of the insurance company to judge the risk based on gender and age. Favoring insurance contracts with deductibles, however, is a signal of the low-risk type.

The Effect of Legal Rules on Signalling

Legal rules can sometimes help to prevent inefficient equilibria in signalling games. Baird et al (1998, p. 143) offer the example of parental leave. Before signing the contract, potential employees might refrain from bargaining for parental leave in order to avoid disadvantageous inferences that the employer could draw. For example, the employer could think that employees with children are less flexible with respect to their working time. Here, workers who are likely to become parents will be tempted to imitate the behavior of those unlikely to become parents and will not ask for a clause on leave in their work contract. Demanding by law that this clause is part of all work contracts solves this problem; however, it also leads to lower average wages as the employers will internalize the extra costs. The outcome under legal regulation is efficient if the total benefit of the workers likely to become parents outweighs the total loss of the workers unlikely to become parents.

Regulation by law could also prevent informative signals. When selling a product, for example, the seller of a product can issue a warrantee to signal the quality to the buyer. The length of the warrantee signals the quality level of the product. A legal rule that mandates a warrantee would suppress this signal and might prevent that different qualities are sold at different prices. The question remains why the producer of a low-quality product has an interest to disclose this fact by offering only limited warrantee, say, only 2 months on an electronic device. To see the logic behind this principle, assume a situation in which all producers with high-quality products disclose this fact by offering a warrantee of at least 3 months while other producers remain silent, i.e., offer no warrantee at all. Without a warrantee consumers will estimate the quality of the product by the average of the unguaranteed products, say, by 1.5 months. This underestimates a product that could be sold profitably with a 2-month warrantee, which explains why the producer has an incentive to disclose this fact. By repeatedly applying this argument, any quality will eventually be disclosed. In economics, this principle is known as the full-disclosure principle (Frank 2010). It says that individuals have an incentive to disclose even unfavorable information; otherwise, their silence is taken to mean that they have something even more unfavorable to hide. The full-disclosure principle also explains why regulations on revealing information are sometimes difficult to be enforced in practice. Consider, for example, questions about marital status, children, or sexual preference which are usually prohibited by law. A job candidate, however, might have an interest to voluntarily share this information if he thinks that this speaks in his favor which leads to the unraveling process of the full-disclosure principle.

More Examples of Signalling in Law and Economics

1. **Product quality assurance.** The quality of many products is not directly verifiable by consumers, especially if a product is new and

consumer ratings are not yet known. The question is how a firm launching a new product can signal its high quality to potential customers. Besides developing a reputation, a firm can signal high quality by extensive sunk costs, i.e., extensive investments that cannot be liquidated like heavy advertising (Klein and Leffler 1981). Such a firm has a high interest to stay in business and have returning customers. This implies that consumers can take substantial sunk costs of a firm as a signal that is too costly to fake when the product is of low quality.

2. **Social norms.** Posner (2000) uses signalling to explain the rise and preservation of social norms (for secondary literature, see McAdams 2001). In line with rational choice scholars, he identifies individual's interest in cooperative opportunities as the main source of norms. The familiar problem in social or economic interaction is that individuals fail to reap all possible gains from cooperation, because defecting from cooperative behavior is a "dominant" strategy in the following sense: it provides a higher individual payoff regardless what others do. This is commonly illustrated by the prisoner's dilemma which is a classic in game theory (see, e.g., von Neumann and Morgenstern 2007). The scenario changes if the interaction occurs more than once, i.e., if the game is played repeatedly. Here, cooperative behavior can thrive because it can induce the other side to cooperate in future rounds while defective behavior may only be punished by defection in the next rounds. That cooperative behavior can arise in repeated games is illustrated by the famous computer tournament conducted by Axelrod (1981, 1984) who elicited strategies from game theorists to compete in a setup of the repeated prisoner's dilemma game. These insights are made precise in the *folk theorems* (for an overview of this large literature, see Fudenberg and Tirole 1991).

On the other hand, if the individual cares much more about immediate benefit than the discounted future payoff, the immediate benefit from defecting will exceed the prospective

gains from future cooperation. In conclusion, the more an individual discounts the future, the more likely she is to choose the one-time benefit from defection and forego future cooperation. In Posner's model an individual is characterized by his or her discount rate which separates individuals into "good" and "bad" types for cooperative relationships. People are concerned with finding and attracting cooperative partners, which, according to Posner, boils down to finding and attracting "good" partners with low discount rates. The good ones are looking for good types in order to reap the repeated gains from cooperation. The bad ones are also trying to attract good ones, but only to profit from the one-time benefit of defecting behavior when the good type cooperates. As a result, the more convincingly a person can present herself as being of the good type, the more cooperative opportunities will be offered to her. People try to "signal" a low discount rate, true or not, by making certain observable choices. As one of the many examples, Posner mentions gift giving. A good type is, other things being equal, more likely to incur a cost now for the sake of future benefits from cooperation. The following example is taken from Posner (2000). Assume that a good type values the future payoff 10 at 10% discount, while the bad type values the same future payoff at 30% discount. This leaves the value 9 for the good type and 7 for the bad type. This means, however, that the good type can distinguish herself by buying a gift that costs 8. The bad type will not do so, because the costs (8) are higher than the prospective benefit (7). This represents a separating equilibrium. A sufficiently expensive gift can therefore be interpreted as the giver trying to signal a low discount rate.

The important point in the gift example is that the costs can be observed by the receiver. Analogously, any behavior that incurs costs can be interpreted as a signal. Posner suggests that in general any conformity move like showing manners or following a fashion trend can be read as an attempt to signal low discount rates. Good types are more likely to make this

investment than bad types. The latter have an incentive to imitate the behavior of good types in order to avoid being identified as bad types. In this sense, Posner suggests that any social norm is the outcome of a signalling game with either pooling or separating equilibria.

3. **Mediation as signal.** When two or more parties are involved in dispute, there is often some resentment in turning to mediation as an alternative dispute resolution. The main reason is that, although mediation officially has to remain strictly confidential, it is difficult to prevent that the information disclosed during a mediation process will be exploited by the other party in court in case mediation fails. Holler and Lindner (2004) argue that this is not the only informational issue at stake. They claim that the call for mediation and the reaction to that call is a signal in the sense of Spence (1973), i.e., it possibly gives away information about the sender.

Game Theoretic Classification of Signalling Models

From a game theoretic viewpoint, a scenario with asymmetric information is a game with private information. In the job market example, the private information is the ability of the employee and hence the individual cost of education. In game theoretic terms, the cost or payoff (utility) of the employee is not known to the employer. Private information can also be information about the condition of a state, say, the knowledge of a market survey that other players do not have. A third possibility is the existence of alternative strategies of a player that other players are not aware of. Games with private information are referred to as games with incomplete information. In order to analyze these games, they are usually reframed with an initial choice of "nature" (Harsanyi 1967, 1968a, b). In the job market example, for example, nature chooses randomly whether the employee is of low- or high-ability type. The probability distribution of this random choice is known to all players (the parameter α in the job market example). In game theoretic terms, a type of a player indicates possible characteristics that a player can have in the view of

all players. This type is characterized by his strategy set, his possible state of information and his payoffs. With the initial random choice by nature all possible private information is included in the model and it is no longer a game with incomplete information. Instead, it is a game with imperfect information, i.e., a game in which not all players are informed about the events that have previously occurred. In the Spence model, the employer is not informed about the choice of nature. Games that have been translated from a game with incomplete information to a game with imperfect information are also referred to as Bayesian games.

Signalling games are a special class of dynamic, Bayesian games with two players, the sender of signals and the receiver. The general formal model can be found in Cho and Kreps (1987). First, player A learns about his type t drawn from a finite set of possible types T , drawn following a probability distribution π which is known by all players. With this private information of his own type, the sender can choose to send a message m from a possible set of message $M(t)$. Player B observes this message and can choose her response from a finite set of responses $R(m)$, depending on the message. The game ends with this response, and the payoff to both players are given by a utility (payoff) function denoted by $u(t, m, r)$ for player A and $v(t, m, r)$.

The common solution concept in signalling games is that of a sequential equilibrium (Kreps and Wilson 1982) which represents a refinement of the Nash equilibrium for dynamic games. A sequential equilibrium specifies not only strategies but also beliefs of the players which justify their strategy. A belief is a probability distribution on scenarios which the uninformed player cannot distinguish. In the separating equilibrium of the job market example, a belief of the employer is that she assigns probability 1 to high ability upon observing an education of at least E^* . In the pooling equilibrium, her belief is $(1 - \alpha)$ that the candidate is of high ability. A combination of strategies and beliefs represents a Bayesian equilibrium if

1. The strategies are best answers in the sense that no player can improve his situation, given the strategies of the others (Nash equilibrium).

2. The beliefs are confirmed on the outcome path of the game using Bayes' rule.

The additional requirement of a sequential equilibrium is that (1) and (2) also holds under small perturbations when the players are forced to choose every strategy with a small probability. This extra condition ensures that the beliefs are also consistent off the equilibrium path.

The concept of a sequential equilibrium is very similar to the (trembling-hand) perfect equilibrium (Selten 1975; Baird et al. 1998). The latter concept also uses perturbations in order to force players to play every strategy with positive probability. Generically (almost always), both concepts provide the same results; however, the conditions of a perfect equilibrium are stricter such that in some special cases sequential equilibria are not perfect. In a nutshell, the difference is that perfectness requires optimal behavior for any nonzero perturbation, whereas the sequential concept only requires optimality in the limit of zero perturbation.

The motivation of refinement concepts of Nash equilibria like sequential or perfect equilibria is to cut out "unreasonable" equilibria; however, in signalling games, this usually still gives rise to a plethora of equilibria. The reason is that the sequential or perfect criterion is not restrictive enough on the possible beliefs off the equilibrium path. In-Koo Cho and David M. Kreps (1987) introduce the so-called intuitive criterion which further restricts out-of-equilibrium beliefs, thereby eliminating unintuitive equilibria.

Signing Without Reading

Gerrit De Geest

Washington University in St. Louis, St. Louis,

Abstract

Most people sign standard term contracts without reading them. This gives drafters an incentive to insert one-sided, inefficient terms. This

problem can be solved directly by giving the drafter a duty to draft efficient terms or indirectly by giving the signer a duty to read (which may remove the incentive to insert one-sided terms if a sufficient number of signers do read the contract). The problem can also be solved in a more draconian way by holding all standard terms unenforceable, irrespective of whether they are efficient or one-sided (as proposed by Radin, Margaret Jane, *Boilerplate: the fine print, vanishing rights, and the rule of law*. Princeton University Press, Princeton, 2013). Finally, the problem can be solved through hybrid instruments – for instance, American law gives the signer a duty to read but intervenes when terms are unconscionable.

In this short chapter, written for Springer's forthcoming *Encyclopedia of Law and Economics* (J. Backhaus, ed.), I argue that a duty to draft efficient terms is the superior instrument. Doctrinally, this means that unread contracts are best seen as agreements to delegate the drafting task to the party that can do so at least costs, as is the case under German law. Because rational parties will never give one of them a wildcard to insert inefficient terms, standard terms should be enforced only to the extent they are efficient. Moreover, economic logic dictates that it should be upon the drafter to prove that the terms are efficient, rather than upon the signer to prove that they are inefficient.

Introduction

Contract law treatises usually assume that parties read contracts before signing them. In the real world, very few people do so. The overwhelming majority of all signed contracts on this planet are standard term contracts, and the overwhelming majority of standard term contracts are never read. This is confirmed by recent empirical studies, which find that very few people even bother to take a look at the contracts they sign, and even fewer spend enough time to understand them (e.g., Bakos et al. 2014; see also Ben-Shahar and Schneider 2014).

Not reading contracts is problematic because it gives self-interested drafters an incentive to insert one-sided, inefficient terms (as empirically confirmed by, e.g., Marotta-Wurgler 2009). For instance, drafters may insert terms that exempt them from any liability for defective products, which may lead to suboptimal incentives to deliver quality. They may also insert terms that redistribute wealth from the signer to the drafter, for instance, through hidden fees. While such terms may not seem inefficient at first glance because they do not destroy wealth but apparently only redistribute it between the parties (for instance, they create a benefit of +3 to the drafter and a cost of -3 to the signer), they may indirectly lead to inefficiency, for instance, by giving the drafter an incentive to induce breach, by discouraging the signer from breaching efficiently, or by discouraging the signer from entering into contracts in which there may be such fees in the first place.

In the absence of any legal intervention, the incentive to insert one-sided terms may be very strong. To illustrate, suppose someone orders a book at a local bookshop. The unread standard terms of the signed book order state that the book has to be picked up within a week after arrival. The buyer picks it up after 2 weeks, thus breaching this term. The unread standard terms contain a \$1 million penalty clause for any breach of contract. If the legal system enforced such terms, a contract drafter could make a million dollars simply by trapping a single consumer.

To be fair, a part of the drafter's benefit from one-sided terms may be passed on to the signer in the form of lower overall prices. Indeed, if drafters can earn rents through inserting one-sided terms, they may want to lower prices in order to attract buyers from whom they can occasionally profit. To what extent price competition will completely eliminate these rents (turning them into quasi-zents) depends on the drafter's market power. In a perfectly competitive market, all of these profits will be passed on to buyers; the result is a pure harsh-term low-price equilibrium (Goldberg, 1974). But competition is rarely perfect. Moreover, the fact that the profits are passed to the "victim" does not make the economic problem

disappear. Harsh-term low-price markets are problematic from an economic point of view for the simple reason that harsh terms are inefficient.

The problem of one-sided, inefficient terms can be solved in four ways. First, it can be solved directly by giving the drafter a duty to draft efficient terms. This is the case under German law, where the signer is presumed to have given the drafter the authority to draft reasonable terms only (see Maxeiner 2003). Second, the problem can be solved indirectly by giving the signer a duty to read; the idea is that if a sufficient number of signers read the contract and walk away when they discover one-sided terms, the drafter may no longer benefit from inserting such terms. Third, the problem can be solved in a more draconian way by holding all standard terms unenforceable, irrespective of whether they are efficient or one sided. Fourth, the problem can be solved through hybrid instruments that combine some of the previous instruments. For instance, American law gives the signer a duty to read but intervenes when the drafter has inserted unconscionable terms.

At the outset, I need to define some terms. First, I will call the two parties the "drafter" and the "signer," respectively. Strictly speaking, the drafter has to sign the document as well; therefore, the term "drafter" refers to the party that drafts and signs the contract, while the "signer" refers to the one that only signs. Second, I will use the term "standard term contract" to denote contract terms that are presented in a take-it-or-leave-it form to more than one buyer. (Note that in some of the literature, the term "adhesion contract" or the more colorful but less rhetorically neutral term "boilerplate" is used instead.) Third, I will distinguish between "efficient terms" and "one-sided terms." "Efficient terms" are given a standard definition: they are terms that increase the contractual surplus by creating obligations that generate a higher benefit to the promisee than they cost to the promisor. "One-sided terms" are given a narrow definition: they are terms that are not only pro-drafter but also inefficient in the sense that they diminish contractual surplus by costing the promisor more than they benefit the promisee. The economic question is indeed not whether the

drafter inserts terms that are to her benefit; the question is whether these terms are efficient. For instance, if the drafter inserts a term that generates a benefit of 3 to her and a cost of 1 to the signer, the drafter does something desirable from an economic viewpoint. But if the drafter inserts a term with a benefit to her of 1 and a cost to the signer of 3, there is an economic problem. Therefore, our focus is on those pro-drafter terms that are also inefficient.

Duty to Draft Efficient Terms (Solution 1) Versus Duty to Read (Solution 2)

Should the drafter be given a duty to draft efficient terms or the signer a duty to read? There are many ways to frame the problem, but they all lead to the same conclusion: a duty to draft efficient terms is a better instrument than a duty to read.

Unilateral or bilateral care problem. Should the drafter abstain from inserting inefficient terms, or should the signer read the contract, or should both do their share of the work to solve the problem? In other words, is this a unilateral care problem (in which only one party has to exert “effort” – the drafter in terms of abstaining from a profitable activity or the signer in terms of spending time to read) or a bilateral care problem (in which both parties should exert effort)? Those who defend a duty to read (a category that includes most American courts) seem to assume (at least implicitly) there is a bilateral care problem. For instance, the click-wrap rule (which states that standard terms should be easy to find rather than buried several clicks away on the website, as is the case with browse-wrap) and the plain English rule (which states that standard terms should be easy to read) seem to be based on the implicit belief that the signing-without-reading problem should be solved partly through more reading.

A more careful analysis, however, tells us that it is a unilateral care problem – though the confusion may stem from the fact that it is a bilateral care problem in individually negotiated contracts.

Reading contracts has a social cost – but what exactly is its social benefit? In individually

negotiated contracts, parties need to exchange information about their idiosyncrasies in order to discover the terms that create the most surplus. Reading contract drafts, under those circumstances, has a clear social benefit – it leads to better, more individualized contracts. Signing without reading in this case is not cooperating to this process and possibly even miscommunicating intentions.

In standard term contracts, however, there is no need to communicate individual characteristics. Standard term contracts are not adapted to individual characteristics – they are offered on a take-it-or-leave-it basis. The social benefit of reading standard contracts is therefore only to discourage drafters from inserting one-sided terms. So in standard term contracts, reading is essentially monitoring the drafter.

The problem can be analogized to theft. Should theft be prevented by giving thieves a direct incentive not to steal (by punishing them when they are caught stealing) or by giving potential victims an incentive to guard their property so that stealing attempts fail? The first-best is obviously the former. If the incentive to steal can be removed, there is no need for victims to guard their property. This differs from typical bilateral (joint) care models in the economic analysis of tort law, in which the first-best is that both parties exert some effort.

To be fair, monitoring someone else (as when potential victims monitor potential thieves) may be a second-best solution when the legal system cannot fully eliminate the first incentive problem. In a society in which theft cannot be completely eliminated because it is too costly for the police to catch a sufficient number of thieves to make theft always unprofitable, it can be desirable, as a second-best solution, to let potential victims invest in surveillance cameras and locks. But in a contractual setting, apprehension rates are naturally high – often even 100 %. If a good is stolen, we may not know who did it, but if a one-sided term is inserted into a contract, we know who did it – the drafter. Moreover, the “wrongdoer” may reveal herself to the legal system by going to court to enforce a one-sided term. In addition, it is sufficient that a single, savvy “victim” discovers the one-sided nature of a term to trigger a

collective enforcement procedure, such as a class action or a suit initiated by an agency or by a state attorney general. Therefore, it is not clear why the legal system should not try to achieve the first-best solution when it comes to the signing-without-reading problem. In addition, if the duty to read were abolished, there would still be a right to read, just like there is a right to place surveillance cameras; so second-best solutions would still be possible.

Permit ex ante monitoring only or permit both ex ante and ex post monitoring? Another way to frame the problem is to analyze it in terms of the well-known distinction between ex ante and ex post monitoring. Ex ante monitoring takes place before the “wrongdoing” may occur; ex post monitoring takes place after the “wrongdoing” occurred. For instance, vehicle safety inspections or speed controls take place before the car driver causes an accident. A tort action is brought after an accident has already happened. Similarly, an employer can prevent theft by its employees by checking them every day before they go home (ex ante) or by starting an investigation after an irregularity has been discovered (ex post).

Reading a contract before signing it is a form of ex ante monitoring. The drafter’s work is inspected before the contract is signed, that is, before the “wrongdoing” takes place. Reading a contract after a dispute has arisen (and refusing to honor one-sided terms) is a form of ex post monitoring. The drafter’s work is inspected after the “wrongdoing” has taken place – that is, after one-sided terms have been inserted into an (apparently binding) contract. The economic literature on ex ante versus ex post monitoring has identified a number of advantages of each (e.g., Shavell 1984). Ex post monitoring has the advantage that it needs to occur less often, that is, only in those cases in which something went wrong (e.g., Shavell 2013, in the context of regulation versus tort law). Ex ante monitoring may be desirable in other cases, for instance, when the harm is irreparable or the wrongdoer is judgment proof. The bottom line is that both ex ante and ex post monitoring can make sense under specific conditions, so that there seems to be no reason to forbid one of these forms of monitoring.

A pure duty-to-read rule permits only ex ante monitoring: if a one-sided term is discovered after the contract has been signed, it is too late. A pure duty to draft efficient terms permits ex post monitoring: if a one-sided term is discovered after the contract has been signed, this term will not be enforced. But a pure duty to draft efficient terms does not forbid ex ante monitoring: nothing prevents a party from reading the contract before signing it and walking away when one-sided terms have been spotted. In this sense, a duty to read permits only ex ante monitoring, while a duty to draft efficient terms permits both ex ante and ex post monitoring. The question can therefore be framed as follows: should ex post monitoring of contract terms be made impossible by the legal system? Framed this way, it is once again obvious that a duty to draft efficient terms is the superior instrument.

Should the legal system correct wrongdoing or should potential victims solely rely on self-help? A third way of framing the problem is to view a pure duty-to-read regime as an instance in which the legal system refuses to intervene when it observes socially undesirable behavior (i.e., the drafter inserting inefficient terms into a contract) but instead requires potential victims to protect themselves by walking away before the socially undesirable behavior takes place. It is not clear, however, why the legal system should tolerate socially undesirable behavior in this case – and even assist the “wrongdoer” by enforcing one-sided terms. Contract law is full of rules that attack undesirable behavior (such as overbreaching, acting opportunistically, misleading, or neglecting to mitigate). Similarly, corporate law (a specific type of contract law) is largely an attempt to prevent self-dealing in one form or another. More generally, modern legal systems consist of millions of rules, and each of these rules, at its most basic level, is designed to prevent some form of socially undesirable behavior. Why should inserting one-sided, inefficient terms receive immunity?

A duty to read is unlikely to be effective. A duty to read tries to solve the drafter’s incentive problem in an indirect way; if a sufficient number of people read the contract, the benefit of inserting

one-sided terms may disappear. The question is what percentage of potential buyers must read the terms before the mechanism becomes effective.

The question can be reframed as follows: for how many buyers is it *individually rational* to read contracts? Reading contracts costs time; understanding contracts costs even more time (Bar-Gill and Warren 2008; Ben-Shahar and Schneider 2014). Apple's iTunes licensing contract, for instance, is 55 pages long. Even a lawyer specialized in licensing contracts may need days to fully understand the significance of all the terms.

In individually negotiated contracts, the incentives to read a contract are stronger than in standard contracts because the reader is likely to internalize a significant share of the surplus created by the better terms. In standard term contracts, there is a gap between what is optimal for all buyers as a whole and what is individually rational for an individual buyer. Preventing the drafter from inserting inefficient terms is a public good for all buyers. Like all public goods, reading terms is associated with collective action problems that are likely to lead to the underprovision of the good (Katz 1990; Bar-Gill and Warren 2008).

As a matter of fact, an equilibrium in which all buyers read the contract can never be individually rational (Katz 1990). Indeed, the only reason to read a contract is to check if it contains one-sided terms. If all buyers read the contract, there will be no one-sided terms. But in that case, individual buyers no longer have an incentive to read the contract. This implies that, in equilibrium, there should be at least some contracts with one-sided terms on the market – otherwise the incentive to read and the equilibrium itself would disappear. Therefore, a duty to read can never *fully* solve the problem of one-sided terms.

What percentage of buyers should read the contract before the self-interested drafter stops inserting one-sided terms? Early economic commentators drew a rosy picture by arguing that, under some conditions, a small number of informed buyers would be enough (Schwartz and Wilde 1979; Trebilcock and Dewees 1981). While this may be true in some cases, it definitely

is not always the case; usually, the required percentage is much higher, and in some cases, the percentage may even be 100 % of the buyers (Gazal-Ayal 2007). In essence, a drafter compares the foregone profits from informed buyers with the increased profits from uninformed buyers. Depending on the magnitude of the parameters, stopping the problem may require few, many, or all reading the contract.

The results are even less rosy when drafters are able to split the informed and non-informed parties (Bar-Gill and Warren 2008). They may do so by offering the informed parties the efficient terms and the non-informed parties the one-sided terms. When such contract term discrimination is possible, one-sided terms will be offered as long as there are some non-informed parties.

Another complication is that, when too few buyers read contracts, all contracts on the marketplace may contain the same one-sided terms. This further undermines the incentive to read the contract.

In sum, a duty to read only prevents one-sided terms if a sufficient number of potential signers read the contract. But in reality, the required quorum is unlikely to be reached because of collective action problems, so that a duty to read is simply ineffective. This is another argument to conclude that a duty to draft efficient terms is the superior instrument.

A duty to read is wasteful when there are many readers. Even in the rare instances in which a duty to read would be effective, it would still be wasteful. Many consumers reading the same contract are a duplicative effort. Information is a nonrival good (that is, a good that, once produced, can be used by an infinite amount of people without being used up). Nonrival goods only have to be produced once. So if all one million consumers of a certain product could meet in a hypothetical world, they would not decide that – say – 500,000 of them would read the contract. Instead, they would pay a professional lawyer to read it for them. From this perspective, rules that encourage reading (such as disclosure rules, the plain English rule, the click-wrap rule, Kim's (2013) proposal for a "duty to draft reasonably," where "reasonably" refers to the communication process not to

the efficiency of the terms themselves; and Ayres and Schwartz's (2014) proposal to make firms put their most surprising terms in a standardized warning box) encourage wasteful behavior.

Doctrinal interpretation – delegation of the drafting task to one of the parties. From a doctrinal perspective, the question is what should be the status of signed terms that have not been read. One view is that these terms are a part of the contract, because a contract is any piece of paper that has been signed by two parties. This view conflicts with the modern view (and “modern” is defined here as the view that is dominant since late medieval times) that holds that a contract is in essence a meeting of minds. In this modern view, signed documents have only an evidentiary function; they help courts to find out what was the meeting of minds. But if courts know that these documents have not been read by one of the parties, then the documents have little evidentiary value with respect to finding the meeting of minds. So in this modern view, what is the status of signed but unread terms?

Under German law, signing without reading is seen as an act of delegation: the task of drafting terms is delegated to one of the parties. Unread terms are binding because the signer agreed to be bound by the terms drafted by the other party (Karl Llewellyn's “blanket assent” theory is a variant of this). But the drafter is presumed to have received only the authority to draft “reasonable” terms. Therefore, standard terms that are unreasonable are not binding; the signer never gave permission to draft such terms.

This view makes economic sense. Rational parties know that default rules are not always efficient (or not always adapted to their idiosyncrasies). Drafting efficient terms is costly and requires expertise. Therefore, they delegate this task to one of them. However, they will never agree to give the drafter a wild card to insert one-sided, inefficient terms because this would violate one of the fundamental principles of rational contracting – that only efficient terms are inserted into contracts.

Rational parties will not even allow one-sided, inefficient terms when the signer would be fully compensated for these terms through a lower price. Indeed, inefficient terms decrease the

surplus, and therefore, it is not possible to find a price adjustment that will make both parties better off. To illustrate, if a one-sided term generates a benefit of 1 for the seller but a cost of 3 to the buyer, the buyer would only agree to such a term if the overall price was decreased by at least 3. But the seller would never forego 3 to obtain a benefit of 1. Therefore, the argument that consumers may not be willing to pay for less one-sided terms (made, e.g., in Ben-Shahar 2013) must assume either that these one-sided terms are efficient or that consumers are uninformed or irrational.

Solution 3: Standard Term Contracts Are Never Binding

This third, more draconian solution has been proposed by Slawson (1971) and recently by Radin (2013). Under this theory, standard terms are not part of the contract because they have not been agreed to. Radin (2013) has argued that inserting egregious, rights-deleting terms should even become a tort.

Extreme as it may sound, this third solution follows in a sense logically from the previously mentioned meeting of minds (or “subjective”) theory. This theory, which is not a minority view but the dominant contract doctrine since late medieval times, holds that a contract is not a ritual nor a piece of paper but two human beings agreeing to be bound by the same terms, that is, having a “meeting of minds.” The document that is signed is thus not the contract but just evidence of the contract. But if courts know that one of the parties signed without reading, the piece of paper loses that evidentiary function. As a consequence, it is not binding – the terms were never agreed to.

From an economic viewpoint, however, this solution throws the baby away with the bath water because it invalidates all unread terms, even the efficient ones. Invalidating all standard terms in practice means that the legal default rules are always binding – as a matter of fact, all default rules then become mandatory rules in contracts that are not individually negotiated. This would be fine if default rules were always efficient and

perfectly adapted to individual situations. But it is hard to see why this would be the case.

Another way of framing the issue is as follows. The drafter has to do a job (draft the contract) and can do a good job or a bad job in this respect. Under the third solution (never enforcing standard terms), the drafter's work is always thrown away, not only when she did a bad job but also when she did a good job. But why would rational parties want to do that? Why would rational parties want to get rid of efficient terms and replace them with less efficient default rules?

Such an extreme remedy is only justifiable when (1) courts can never determine at all whether terms are efficient or inefficient and (2) courts know that standard terms are on average more inefficient than default rules. But if condition (1) is fulfilled, how could condition (2) be fulfilled – that courts know that their own gap-filling rules are better than the invalidated terms they replace? Indeed, if courts (or legislators) have no clue which terms are efficient, they will choose no better terms than those who simply flip a coin. Drafters who chose only pro-business terms may also get it right in 50 % of the cases (at least if the set of efficient terms contains 50 % pro-business and 50 % pro-consumer terms; that is not necessarily the case, but it may be the most rational assumption in the absence of more specific empirical information). Also, courts can read scholarship (or consult experts), and therefore, condition (1) comes down to the condition that scholars can never figure out which *types* of terms are efficient. This is not very plausible – even those who are skeptical about the practical value of scholarship tend to believe that scholars can at least get some things right. Moreover, if scholars could never figure out whether terms are efficient, how could courts once again know that condition (2) is satisfied that standard terms are on average more inefficient than default rules?

Solution 4: A Duty to Read with an Unconscionability Exception

This is the current solution in American common law. Unread contract terms are legally binding,

unless they are unconscionable. “Unconscionability” is a notoriously vague concept that typically requires that terms be clearly unreasonable, “egregious,” or, as one judge famously put it, “shock the consciousness.” (At least, this is the definition of substantive unconscionability; most American states also require procedural unconscionability, but this condition is easily met in practice for adhesion contracts). Although translating such vague criteria into precise economic jargon is always speculative, the criterion seems to be that terms are only invalid when they are clearly inefficient.

Still, at the end of the day, the question can be asked whether the difference between solution 1 (the German regime) and solution 4 (the American regime) is not chiefly a matter of evidentiary burdens. Indeed, solution 1 (a duty to draft efficient terms) holds that terms are binding *only if* they are efficient. Solution 4 (a duty to read terms except for when they are unconscionable) holds that terms are binding *unless* they are clearly inefficient. And this raises the next question: who should bear the burden of proof of (in)efficiency?

There are two main considerations here – the relative evidence cost to the parties and the likelihood of the hypothesis; see, e.g., Hay and Spier (1997) – and they both lead to the conclusion that the drafter should have the burden of proof. First, the drafter has more information on why terms are efficient or inefficient. After all, the drafter is the expert, who also has economies of scale, and drafting is at its core determining which terms are efficient. Accordingly, when the drafter drafted in good faith, she only deviated from default rules when she had reasons to believe that other terms created more joint surplus; since she must already know these reasons, she can reveal them at little cost. In sum, the drafter is the least-cost evidence gatherer.

Second, to the extent that evidence is inconclusive in either direction, the question is whether we have reasons to believe that markets will usually get it right or wrong. (Indeed, from a Bayesian perspective, the “prior” will dominate when the “posterior” is weak). And here, there is a difference between individually negotiated and adhesion contracts. For individually negotiated

contracts, there are theoretical reasons to believe that markets will in principle lead to efficient terms; after all, markets tend to work well when parties are well informed. For adhesion contracts, however, the theoretical reasons point in a different direction. Indeed, markets tend to fail when one of the parties is completely uninformed. Since signers almost never read the contract, the natural incentive for the drafter is to insert only terms that are beneficial to the drafter. If these terms also turn out to be efficient (that is, if the cost to the signer turns out to be lower than the benefit to the drafter), that is pure coincidence. So there is no *a priori* reason to presume that unread terms will be efficient. Therefore, there is no reason to enforce them when the drafter cannot prove their efficiency.

Simple Majority

Silvia Fedeli

Department of Economics and Law, Sapienza - University of Rome, Rome, Italy

Definition

Simple majority (SM) is a voting system whereby the highest number of votes for one alternative within those under decision designates the winner. It may refer to a voting requirement of *half* of either all ballots cast or those voting on the given alternative *plus one* and also to the highest number of votes cast for any one alternative, while not constituting a majority.

Whenever a collective decision has to be taken, SM seems the natural way to reach a solution.

Various reasons for SM's wide use have been given in the literature. May (1952), studying the issue of the relation between group choice and individual preferences in the presence of two alternatives, showed that SM is always: *decisive* (each

set of individual preferences leads to a defined/unique group choice), *egalitarian* (interchanging any two preferences of the voters, the result is unchanged, which implies anonymity/equality of voters), *neutral* (it does not favor either alternative), and *positively responsive* (if the group decision is indifferent or favorable to x and, *ceteris paribus*, a single individual changes in favor of x , then the group decision becomes favorable to x).

A further justification for the choice under SM rule has been proposed by Rae (1967) and Taylor (1967) who show that, under restrictive assumptions, SM maximizes the expected utility under the veil of ignorance.

When there are more than two alternatives, SM rule must be redefined. This, however, turns out to be tricky. The most direct method consists in confronting/voting all possible combinations in individual pairs. Each individual when confronted with any pair either prefers one or the other or is indifferent. The alternative with the highest number of preferences/votes in all pairings prevails and is called the *Condorcet winner* (Condorcet 1785). The problem is that (unlike the case of a single pair of alternatives) a Condorcet winner might not exist, and collective preferences can be cyclic (not transitive), even if the preferences of individual voters are not (*voting/Condorcet's paradox*).

Several variants of the above method differ on how they resolve such ambiguities to determine a winner. One strategy consists in arranging the alternatives in a type of elimination tournament: alternatives are paired off against each and the one chosen by SM advances to a subsequent round, while the loser is eliminated. This system can produce a group favorite and, by repeatedly invoking the system on the remaining alternatives, also a group ranking. However, the outcomes are susceptible of *strategic agenda setting*.

A different strategy (*Borda count*) tries to produce a group ranking directly from the individual rankings: each alternative is assigned a *weight* based on its positions in all the individual rankings, and the alternatives are then ordered according to their total weight (Borda 1781). Like other variants, these *positional voting systems* can originate a complete, transitive ranking

for a set of alternatives. But they suffer if competition for top spots in group ranking critically depends on the rankings of alternatives that are further down in the list. This, in turn, might induce *strategic misreporting of preferences*.

Do All These Variants Aiming to Solve the Condorcet's Paradox Mean that We Cannot Properly Decide Under SM?

In this respect, it is important to know both the probability of the paradox actually taking place and the restrictions on individual preferences that assure a Condorcet winner.

As for the probability of a cycle in collective preference, some scholars calculated that it is increasing with the number of voters and of alternatives under vote (for a survey, see Sen 1970). With three alternatives the probability is less than 10% for any number of voters, whereas with 50 alternatives and many voters, the probability of a cycle is about 90%.

This makes the second issue quite relevant: is it possible to find restrictions on individual preferences that exclude cycles?

The most famous condition is known as single peakedness. Black (1948) and Arrow (1951) showed that if all individual rankings are single peaked, then SM applied to all pairs of alternatives produces a group preference relation that is complete and transitive, so that we could produce a group ranking from it. This observation led to the *median voter theorem*, which is the basis of Downs's (1957) economic theory of democracy: with single-peaked rankings, an odd number of voters, the median individual favorite defeats every other alternative in a pairwise majority vote.

Thus, at least in this case, a decision can be taken, **but what is the quality of the decision taken by most voters? What gives most voters the right to decide for all? Moreover, SM rule presumes that all persons are equal, but what about equal ability/capability?**

Sed hoc pluribus visum est. Numerantur enim sententiae, non ponderantur; nec aliud in publico consilio potest fieri, in quo nihil est tam inaequale quam aequalitas ipsa. Nam cum sit impar prudentia, par omnium ius est. (Plinio 2 ep.12)
(But the majority gave their assent; for votes are

counted, their value is not weighed, and no other method is possible in a public assembly. Yet this strict equality results in something very different from equity, so long as men have the same right to judge but not the same ability to judge wisely. (THE LETTERS OF PLINY, Translated by Betty Radice, Loeb Classical Library 55, p. 121))

In other words, if the basis of SM is merely quantitative and not qualitative, then the resulting choice is not necessarily the best a community can make, and it is based on the reason of the strongest. Moreover, if equality depends on quantity of equal individuals, what follows is the sovereignty of the multitude and the oppression of minorities (Aristotele, *Politica* VI, 1, 6). Finally, SM rule might give ambiguous outcomes in case of “absences” and “votes to abstain” (this issue shall not be considered here, but see Freixas and Zwicker 2003, 2009; Zwicker 2009).

Nevertheless, any society has got elementary needs including that of collective decision making.

The first organized collective choices probably date back to ancient Greece, where the assembly acclaims and a leader judges prevalent favor depending on the shriek’s intensity. This means majority voting without vote count/scrutiny, with Sparta improving the method for the election of Gerontes, through the guarantee of an impartial judge (Aristotele, *Politica* II, VI, 16; on Sparta also, see Tucidide, I, 87).

In Rome the majority principle was precluded in most cases, with the prevailing rule for collective choices being the *ius prohibendi* = right of veto. Nevertheless, Romans classified the majority rule into the juridical system by means of a legal *fictio*. The decision of the majority is valid as it would be approved by all: “*quod maior pars curiae efficit, pro eo habetur ac si omnes egerint*” (“The decision taken by the majority of the senators is valid as it would be approved by all.”) (Scevola); “*refertur ad universos quod publico fit per maiorem partem*” (Ulpian). But the law recognizes only majority and assigns no right to minority.

Although the fortune of this legal *fictio* was enormous in the Middle Ages, for collective decision the primitive Church superimposed God’s will to human will, thus recovering the qualitative criterion. This precluded SM, implying that if the

majority represents God’s will, the minority denies it, which is, per se, against the dogma that the Christian community represents the body of Christ. Therefore, the Church stuck to unanimity for a long time, in spite of some problems during the Councils solved via excommunication/persuasion/conversion. The First Council of Nicaea (AD 325) produced the “Nicene Creed”: only two bishops voted against it and were excommunicated. In the Council of Chalcedon (AD 451), a minority of Egyptian bishops (12 over 600) were thought suitable for conversion.

When conversion was not possible, the Church resorted to the theory of *sanioritas* accompanying SM: the electoral bodies in the Church have the right to vote and the moral duty/obligation to vote right/well, i.e., according God’s will as recognized by a hierarchical superior. The Third Council of the Lateran (1179) accepted the Roman *fictio* only if driven by the qualitative principle of *sanior pars*. Only for the election of the Pope a majority of two third is required, with the quantitative principle merely invoked because of the absence of a superior among voters.

Without *sanioritas*, the quantitative principle simply means that force prevails (the louder *vox* or *voice* or *voix* and later *vote*, often accompanied by the din of arms) and the defeated minority has no rights, which is exactly the system used by some primitive societies:

“Si displicuit sententia, fremitu aspernantur; sin placuit, frameas concutunt. Honoratissimum adsensus genus est armis laudare” (“If his sentiments displease them, they reject them with murmurs; if they are satisfied, they brandish their spears. The most complimentary form of assent is to express approbation with their spears.”). (Tacitus, *Germania* c.11); “*Conclamat omnis multitudo et suo more armis concrepat*” “The whole multitude raise a shout and clash their arms, according to their custom” Julius Caesar. Caesar’s Gallic War. Translator. W. A. McDevitte. Translator. W. S. Bohn. 1st Edition. New York. Harper & Brothers. 1869. Harper’s New Classical Library.)

For this reason, only after the twelfth century in the Italian Medieval communes/municipalities, we find the first examples of the use of SM, whereas even the English Parliament of the origins preferred unanimity/acclamation as ideal procedure, and

only in 1554 the Parliament approved the first law by majority rule (Ruffini 1927).

It seems striking that the theory supporting majority rule only dates back to Jusuaturalism. This is mainly developed in Germany and basically assumed that the *first social contract* ought to be based on unanimity, with SM operating afterward, and being valid over the whole community, only because so established by the fundamental social contract. Grotius, first, formulated this theory; the last was Kant (notably relevant contributions are due to Pufendorf, Wolff, Hobbes, Locke, Ickstatt, Cocceius, Meyer, Rousseau, and Fichte).

But Still the Question Remains on Why a Quantity Gives a Right? And What Is the Value of the Biggest Number of Votes?

Unexpectedly, a partial answer and a rational interpretation of the majority will as the outcome closer to the truth are a mathematical one and come from Condorcet (1785): the probability for a majority outcome to be close to the truth increases with the number of voters and depends on the probability (higher than one half) that the individual voter correctly votes. This led to the *Condorcet jury theorem*. If x is the best alternative between two and each voter chooses the best alternative with some probability $p > \frac{1}{2}$, then the probability of the majority reaching a correct decision converges to one as the number of voters increases. In this sense, the theorem is an explicit formulation of the “wisdom of crowds”: aggregating the estimates of many people can lead to a decision of higher quality than that of any individual expert.

Unfortunately, the theorem does not directly apply to decisions with more than two alternatives. Moreover if $p < \frac{1}{2}$, then adding voters makes things worse: the optimal jury consists of a single voter.

Thus, we are back to our original problem, with no decisive answer on whether a rational reason, other than simply necessity, does exist as to why the minority ought to follow the will of the majority that the former does not want (the latter issue is also related to two other problems, not considered here: “tyranny of SM” (Forte 1985) and “logrolling” (Tullock 1959)).

If we have to abandon the hope to find an ex ante legitimation of the majority principle, valid for any type of society/institution, let us look at whether it is possible to find a moral foundation.

But Here We Come Back the Question About the Value of the Opinion of the Multitude

The answer would simply be:

“Was ist die Mehrheit? Mehrheit ist der Unsinn, Verstand ist stets bei wen’gen nur gewesen. (...) der Staat muß untergehn, früh oder spät, wo Mehrheit siegt und Unverstand entscheidet“. (“Majority? The majority is madness;

Reason has still ranked only with the few.

(...)

‘Twere meet that voices should be weighed, not counted.

Sooner or later must the state be wrecked, Where numbers sway and ignorance decides.”

Friedrich Schiller, Demetrius, The Perfect Library (p.18), 2010.)

or else

“La justice est sujette à dispute. La force est très reconnaissable et sans dispute. (...)Et ainsi, ne pouvant faire que ce qui est juste fût fort, on a fait que ce qui est fort fût juste”. (“Justice is subject to dispute, power is easily recognised and cannot be disputed. Thus we cannot give power to justice, because power has arraigned justice, saying that justice is unjust, and she herself truly just; so since we are unable to bring about that what is just should be strong, we have made the strong just.” (Pascal, p.67, THE THOUGHTS OF BLAISE PASCAL, translated from text of M.A. Molinier by C. Kegan Paul, London, George Bell And Sons, 1901.)

If SM is recognized to be irrational, neither just nor good, but only based on the reason of the strong, should it be avoided for social choices? Most scholars would answer *no* at least on the basis of Descartes’ “*une morale par provision*” or because, as in Bentham, SM although far from unanimity is closer to it than the opposite vote.

Justifying the majority rule is probably difficult simply because it is not a legal institute; it is rather a legal formula, which means that it does not have its own *raison d’être*, but it may get one, depending on how and where it is applied (Ruffini 1927).

Slavery

Jenny Bourne

Carleton College, Northfield, MN, USA

Abstract

Slavery is fundamentally an economic phenomenon; it occurs when the net benefits to free society are positive. From antiquity until the mid-twentieth century, slavery was primarily a profitable way of organizing the labor force, at least to those other than the slaves

themselves. Slave societies passed laws to perpetuate the peculiar institution, often acknowledging both the property value and the personhood of slaves.

Much scholarly research focuses on the enslavement of Africans on several continents starting in the mid-1400s, the subsequent four centuries of the transatlantic slave trade, and the plantation economies of the New World. But slavery has thrived in many parts of the world for most of human history, with slaves representing productive investments and tradable wealth for their owners. More recent forms of slavery depart from this pecuniary model – enslaved political enemies may not yield monetary rewards but instead serve as symbols of dominance for tyrannical governments. Nonetheless, slavery and the legal and political institutions that support it have largely been driven by economic factors.

Overview

Throughout history, slavery has existed where it has been economically worthwhile to those in power. Certain conditions enhance the probability that any given society might hold slaves – cheaply obtained supplies of foreigners with distinctive features, division of production processes into series of simple and easily monitored tasks, and well-developed commodity markets – but slavery has flourished in many places, regardless of religion, climate, or cultural attainments.

Slavery has features in common with other forms of coerced labor. Yet slavery is a species of servitude set apart: slaves typically have been aliens with minimal freedom of action, permanently deprived of the title to their human capital and, if female, to their children, and often with no higher authority than their masters.

Central to the economic success of slavery are political and legal institutions that validate the ownership of other persons. Some slave societies have considered slavery part of the natural order; others have viewed slavery as established only by positive law. Regardless of philosophy, nations have crafted finely nuanced legal rules that acknowledge the

peculiar nature of slaves as both property and persons. Most scholarship on slave law focuses on the US South, although scattered information about other jurisdictions is also available.

The law has generally considered slaves as personal chattels (movable wealth), although late Roman and Louisiana law sometimes classified slaves as chattels real, precluding their sale separate from land. Like other chattels, slaves and their offspring could typically be bought, sold, hired, exchanged, given, bequeathed, seized for debts, and put up as collateral. What few protections slaves have had typically stemmed from a desire to grant rights to their owners. Still, when slaves stole, rioted, set fires, or killed free persons, the law usually subverted the property rights of masters so as to preserve slavery as a social institution (Bourne 1998).

Early Slavery

Slavery likely developed after civilization turned from hunting to pastoral societies: agriculture brought specialization of tasks and opportunities for exploiting another's labor. Ancient Sumerian, Phoenician, Hebrew, Babylonian, and Egyptian societies used slaves to tend flocks, work fields and mines, and help with domestic chores (Finley 1961, 1987; Drescher and Engerman 1998).

Slavery flourished in the classical period, predominantly in cities open to commercial exchange. Greek slaves worked in mines, quarries, fields, handicrafts, and domestic, police, and secretarial work; skilled slaves often lived apart from their masters. A unique feature of Greek society was benefit clubs that lent slaves money to buy their freedom (Finley 1961).

Rome inherited the slave trade and expanded it by allowing field commanders to dispose of prisoners as they wished. Consequently, slave dealers traveled with the armies and conducted on-the-spot auctions. Slaves comprised about 30% of the population in Rome's heyday. Roman slaves enjoyed limited freedoms – they could acquire property and schooling and, unlike Greek slaves, citizenship upon manumission (Finley 1961, 1987).

Slavery declined – but did not end – with the decline of Rome. The Germanic tribes held slaves, sometimes using long hair as an identifying mark. Although the church tried to prohibit the slave trade in the early ninth century, it failed: the trade was one of the West's few sources of the foreign exchange necessary to purchase Eastern goods. Charlemagne's efforts to reunify Western Europe finally sparked the transition to serfdom there (Phillips 1985).

Elsewhere, slavery persisted. With the emergence of Islam along the Arabian peninsula, religious wars generated large slave populations, mostly used for domestic and military service. William the Conqueror ended the export of English slaves, but serfdom did not replace domestic slavery in England until about 1200. Scandinavians held and traded thralls until the Swedish king declared all offspring of Christian slaves free in 1335. Slavery continued unabated in Italy and the Iberian peninsula for decades, however. Genoa and Venice had active slave markets in the thirteenth century, Seville and Lisbon two centuries later. Captains of Prince Henry the Navigator brought the first black slaves to Portugal in the 1440s (Phillips 1985; Meltzer 1993; Drescher and Engerman 1998).

Out of Africa

From 1500 to 1900, an estimated 12 million Africans were forcibly taken west to the New World, with about two million dying en route. Nearly three million departed between 1811 and 1867 alone. An additional six million African slaves were sent from sub-Saharan Africa eastward to Arab, Asian, and even some European countries; another eight million remained enslaved on their own soil (Lovejoy 1983).

African slaves came with Europeans to the New World from the very beginning. Slaves accompanied Ponce de Leon to Florida in 1513, for example. The first African bondsmen in what became British North America arrived in Virginia in 1619 on a Dutch ship (Fogel 1989).

But institutional trading arrangements soon replaced small-scale trafficking. Although early

Spanish settlers at first enslaved native Americans, the indigenous population perished in droves from smallpox and punishingly hard work. Via licensing agreements, Portugal and Spain began importing African slaves into their colonies in the early 1500s to replace the dying natives. In 1517, Charles I began to import Africans to the West Indies and the Spanish-controlled mainland. Brazil commenced legal importation of black slaves in 1549. Traders could acquire slaves in specific African zones, then sell them in America – up to 120 per year per Brazilian planter, for example (Blackburn 1997).

Britain eventually replaced Spain and Portugal as the major slave-trading nation. Elizabethan-era captain Sir John Hawkins had transported slaves, but England did not figure large in the African trade until the seventeenth-century Royal African Company became the biggest slaver in the world (Galenson 1982).

The Atlantic slave trade created an infamous “triangle.” European captains plied the West African chieftains with liquor, guns, cotton goods, and trinkets. In exchange, Africans supplied slaves to suffer through the arduous “middle passage.” Slaves worked on sugar plantations in the West Indies, grew coffee and mined metals in Brazil, and raised tobacco, sugar, rice, and cotton in North America. These goods, along with molasses and rum, went back to England (Solow and Engerman 1987).

Many interests benefited from the Atlantic slave trade, including ship captains, European financiers, African dealers, and American industrialists. The Royal African Company was hardly a monopoly – individual ship captains earned upwards of a 10% return on slave cargo (Eltis 1987; Drescher 1999). European banks and merchant houses profited from lucrative credit and insurance arrangements with New World plantation owners (Engerman 1972; Menard 2006). African tribes sold slaves for horses and guns, then used these items to obtain more slaves (Lovejoy 1983). New England shipbuilders and textile producers also had strong connections to the slave trade and slavery (Bailey 1990).

Few imported slaves actually ended up in the United States. When the transatlantic trade to the

United States officially ended in 1808, only 6% of African slaves had come to North America. The remainder went further south, with the majority landing in the Caribbean and the rest primarily in Brazil (Fogel 1989; Blackburn 1997; Manning 2006).

Importation of slaves remained key for decades in keeping Caribbean plantations viable. In Jamaica, for example, the black population did not become self-sustaining until after the mid-1830s (Fogel and Engerman 1974, Menard 2006). The total Caribbean slave population increased from 150 thousand in 1700 to 1.2 million in 1790, with slaves comprising about 90% of the population in the late eighteenth century (Menard 2006).

Slavery in the US South was unique in that the rate of natural increase among enslaved blacks was nearly as large as among free whites. Compared with elsewhere in the New World, slave mortality rates in the South were lower due to a milder climate and less grueling tasks, and the ratio of females to males was far less skewed (Engerman and Genovese 1975; Solow and Engerman 1987). Among those who supported the closing of the transatlantic slave trade, in fact, were Southern slaveowners, who expected that reduced supply would drive up slave prices and hence their personal wealth. Because of the high fertility and low mortality rates among Southern slaves, masters did not fear a long-term shortage. Slaves comprised less than a tenth of the total Southern population in 1680 but grew to a third by 1790. After the American Revolution, the Southern slave population exploded, reaching about 1.1 million in 1810 and over 3.9 million in 1860. By 1825, 36% of the slaves in the Western hemisphere lived in the United States (Fogel 1989).

Slave Productivity

Slave trading was profitable because slavery was profitable. As Moses Finley (1961) puts it, Greek and Roman slaveowners went on for centuries believing they were making profits – and spending them. Robert Fogel and Stanley Engerman,

along with several of their students, have amassed empirical evidence that has convinced most scholars that slaves in the US South (particularly in agriculture) were far more productive than free Northern laborers. Slavery also worked well in industry and in urban areas (Goldin 1976; Dew 1991); in fact, workers at the Tredegar Iron Works in Richmond, Virginia, went out on their first strike in 1847 to protest the use of slave labor (Bourne 1998).

A large proportion of the reward to owning slaves resulted from innovative labor practices among growers of cash crops (Fogel and Engerman 1974). The use of the “gang” system in agriculture contributed to profits in Roman times as well as in the antebellum period. In the West Indies, for instance, sugar slaves worked in three separate gangs: one harvesting the crop, a second cleaning up after the first, and a third bringing water and food to the others (Dunn 1972; Menard 2006). Cotton planters in the US South also used the gang system to their advantage (Fogel and Engerman 1974).

Integral to many gang-oriented operations across the Americas were plantation overseers. The vigorous protests against drafting overseers into military service during the US Civil War confirm their significance. Yet law and custom alike circumscribed overseers’ abilities to administer correction, because slaves represented so much wealth to their masters (Bourne 1998). This balance between authority and accountability worked well enough to turn handsome profits for many planters, particularly those who entrusted reliable slave drivers as liaisons. By the mid-1820s, black slave managers actually took over much of the day-to-day operations in the West Indies (Dunn 1972).

Slaveowners experimented with other methods to increase productivity. Southern masters developed an elaborate system of “hand ratings” to improve the match between slave worker and the job. Slaves sometimes earned bonuses or quit early if they finished tasks quickly. Slaves – in contrast to free workers – often had Sundays off (Fogel and Engerman 1974, Fogel 1989). Some masters allowed slaves to keep part of the harvest or to work their own small plots. In places, slaves

could even sell their own crops and produce. To prevent stealing, however, many masters limited the crops that slaves could raise and sell, confining them to corn or brown cotton, for example. Masters capitalized on the native intelligence of slaves by using them as agents to receive goods, keep books, and the like (Bourne 1998). In some societies – for example, ancient Rome and her offspring, antebellum Louisiana – slaves even controlled a sum of money called a *peculium* (Schafer 1994). This served as a sort of working capital, enabling slaves to establish thriving businesses that often benefited their masters as well.

Slave Sales and Prices

Slaves benefited their owners via their marketability as well as their productive labor. Healthy male slaves were sold for a date plantation grove in Sumeria in 2000 BC. In early Athens, slaves cost about a year’s keep; prices soon rose significantly as slaves went to work as managers, secretaries, and civil servants. Eight oxen bought a slave among Anglo-Saxon tribes in the mid-400s (Finley 1961, 1987; Meltzer 1993). Prime field hands went for about five hundred dollars in the United States in 1800, about fourteen hundred dollars in 1850, and up to three thousand dollars on the eve of the Civil War (Fogel and Engerman 1974).

Several early societies set up thriving slave sale markets. Greek slaves were sold with other commodities in the agora. Judging from the distribution of Italian wine jars in Gaul, wine was evidently exchanged for Gallic slaves in the first and second centuries BC. Hernando Cortés described the large number of slaves brought to the great marketplace near Tenochtitlan (present-day Mexico City) (Phillips 1985; Watson 1987; Meltzer 1993).

Slave markets also existed across the antebellum US South. Even today, one can find stone markers like the one next to the Antietam battlefield, which reads: “From 1800 to 1865 This Stone Was Used as a Slave Auction Block. It has been a famous landmark at this original location for over 150 years.”

Professional traders facilitated exchange. Established dealers like Franklin and Armfield in Virginia and Nathan Bedford Forrest (Confederate cavalry officer and later Ku Klux Klan leader) in Tennessee prospered alongside itinerant traders who operated in a few counties, buying slaves and moving them in chained coffles to the lower South (Bancroft 1931).

Prices served as signals of market conditions. The price of Egyptian slaves in the fourth century dropped dramatically, for example, when the sale of babies became legal (Finley 1961). Conversely, the price of US slaves rose upon the close of the international slave trade, as did European slave prices after the ravages of the Black Death. Slave prices fell with cotton prices in the 1840s but rebounded in the 1850s as the demand for cotton and tobacco grew (Fogel and Engerman 1974, Fogel 1989). Slavery in the US South remained a thriving business on the eve of the Civil War: even controlling for inflation, slave prices rose significantly in the six decades before secession. By some estimates, average slave sale prices by 1890 would have increased more than 50% over their 1860 levels had war and emancipation not occurred (Fogel 1989).

Studies reveal that the prices of slaves also varied by their sex, age, skill levels, and physical condition (Fogel and Engerman 1974; Phillips 1985; Fogel 1989). Prices generally rose as slaves acquired strength and experience when they approached puberty; prices declined after slaves reached their mid-twenties (Kotlikoff 1979; Engerman and Genovese 1975; Fogel 1989).

One pricing variant appeared in the West Indian “scramble.” Here, owners and agents devised a fixed-price system, dividing slaves into four categories, penning them up accordingly, and assigning a single price per pen. Potential buyers then jumped into the pens, attempting to pick off the best prospects for the price (Dunn 1972; Menard 2006).

An interesting influence on prices has to do with childbearing. Fertile female slaves were sold for a premium in the US South because slaves’ expected life span was long enough that infant slaves had positive sale value (Fogel and Engerman 1974). In contrast, men who

impregnated female slaves in medieval Italy had to compensate their masters – because childbirth deaths were so common. Genoan men could even buy indemnification insurance against this possibility (Meltzer 1993).

Along with US slave sale markets came sophisticated methods for coping with risk, such as explicit – and even implicit – warranties of title, fitness, and merchantability (Bourne 1998). Legally, slave sellers were responsible for their representations, required to disclose known defects in their wares, and often liable for unknown defects, as well as bound by explicit contractual language. These rules stand in stark contrast to the *caveat emptor* doctrine commonly applied to antebellum commodity sales. South Carolina and Louisiana were particularly pro-buyer in slave sale cases.

One feature concerning slave sale laws deserves mention. If a slave was seized and sold unlawfully by someone other than his master, Southern courts often decided that the slaveowner was entitled to the return of his slave rather than mere money damages because, as a North Carolina court stated in *Williams v. Howard* (1819): “[F]or a faithful or family slave, endeared by a long course of service or early association, no damages can compensate; for there is no standard by which the price of affection can be adjusted, and no scale to graduate the feelings of the heart.”

Slave Hiring

Robust slave-hiring markets existed as well as slave sale markets. In the United States, slave hiring took root by the Revolutionary Period and thrived throughout the antebellum period (Martin 2004). Hiring mattered both in industry and agriculture; it was frequently used to keep slaves occupied during slack growing seasons and after an owner died but before the estate was settled (Goldin 1976; Dew 1991). Annual hire rates for young adult males approached \$150 during the 1850s.

Bond and free workers both faced a legal burden to behave responsibly on the job. Yet the law of the workplace differed significantly for the two (Bourne 1998). When free laborers suffered

injuries and brought suit, antebellum judges nearly always sided with employers. Under the doctrine of *Baker v. Bolton* (1808), English and American courts held that torts died with victims. In contrast, slaveowners often recovered damages for injuries to hired slaves. And, because the “victim” in a slave-hiring case was the master, courts did not apply the *Baker* rule.

People had duties to treat hired slaves the same as slaves they owned. Hirers retained authority to direct and discipline slaves; otherwise, they might not have elicited work. Masters feared slave exploitation, however, and often specified tasks and work locations in hiring contracts (Bourne 1998). Hirers paid when they violated such clauses, even if slaves had been disobedient, suicidal, drunk, or careless. Negligent hirers also paid for escaped slaves. But Southern hiring law recognized the personhood of slaves as well. If hired slaves were hurt or killed through their own carelessness, the loss fell on their owners as long as employers had complied with contracts. Courts also relieved employers of liability when slaveowners knew about risks of jobs their slaves were to perform.

Laws Governing Those Other than Slaveowners

Society at large shared in maintaining the machinery of slavery. In the United States, for example, all Southern states save Delaware passed laws to establish citizen slave patrols. Northern citizens often worked hand-in-hand with their Southern counterparts, returning fugitive slaves to masters either with or without the prompting of national and state law. Yet not everyone was civic-minded. As a result, the profession of “slave catching” evolved – often highly risky (enough so that insurance companies denied such men life insurance coverage) and just as often highly lucrative (Bourne 1998).

Slaves, like other chattels, constituted valuable cargo on common carriers. Unlike inanimate goods, slaves could escape from danger. But cargo they nonetheless were – unlike free passengers, slaves embodied large and easily calculated property values. Consequently, US Southern law

regarding slaves injured in transport struck a balance between the strict-liability standard governing goods and the no-liability standard for passengers (Bourne 1998).

Slaves also suffered wounds or death in accidental collisions, particularly with trains. Although some states held railroad companies strictly liable for injuries to livestock, legal authorities refused to do the same when slaves were hurt. In fact, early court opinions favored transportation interests in railroad mishaps involving any person, slave or free. But, over time, Southern courts modified liability rules: common-carrier defendants that had failed to offer slaves – even negligent slaves – a last clear chance to avoid accidents ended up paying damages to slaveowners. Slaveowner plaintiffs won several cases in the decade before the Civil War when engineers failed to warn slaves off the tracks. This “last-clear-chance” rule did not generally apply to free victims until the twentieth century (Bourne 1998).

US Southern law also shaped interactions among slaves and strangers, awarding damages more often for injuries to slaves than injuries to other property or persons, shielding slaves more than free persons from brutality, and generating convictions more frequently in slave-stealing cases than in other criminal cases (Bourne 1998). The law also recognized more offenses against slaveowners than against other property owners because slaves, unlike other property, succumbed to influence.

Despite some restrictions, strangers could discipline slaves in many circumstances and could defend themselves from slaves. Still, they faced civil and criminal penalties for wanton assaults. By comparison, free persons in the US South virtually never recovered civil damages nor saw criminal sanctions applied in assault cases.

Just as assaults of slaves generated civil damages and criminal penalties, so did stealing a slave to sell him or help him escape to freedom. Many Southerners considered slave stealing worse than killing fellow citizens. The counterpart to helping slaves escape – picking up fugitives – also created laws. States offered rewards to defray the costs of capture or passed statutes requiring owners to pay fees to slave catchers.

Among the South's concerns were activities that weakened masters' authority. Most states prohibited the sale of spirits to slaves and passed statutes to outlaw slave assemblies. Many states also forbade the sale or delivery of poison to slaves and imposed fines on people who bought goods from slaves.

The Master-Slave Relationship

In spite of the necessary subjugation entailed by slavery, the law – particularly in the 30 years before the US Civil War – limited owners somewhat (Bourne 1998). Southerners feared that unchecked slave abuse could lead to unpleasant scenes of pilfering, public beatings, and insurrection.

Many states required masters to give adequate food and clothing to slaves, just as states later required livestock owners to tend to their animals and – much later – made household heads provide for their families. Most states stopped short of permitting people to kill slaves; North Carolina, Alabama, Mississippi, and Virginia were willing to convict masters who had murdered their own slaves. Colonial South Carolina and Georgia restricted nonfatal abuse as well as murder, although Virginia, North Carolina, Maryland, and Delaware did not. Later on, the codes of ten Southern states instituted fines or imprisonment for cruel masters. Still, prosecuting masters was extremely difficult, because often the only witnesses were slaves or wives, neither of whom could testify against male heads of household.

Southern law encouraged benevolence, at least if it tended to supplement the lash and shackle. Court opinions indicate the belief that good treatment of slaves could enhance labor productivity, increase plantation profits, and reinforce sentimental ties. Courts also permitted slaves small diversions, such as Christmas parties and quilting bees, despite statutes that barred slave assemblies.

The master's ultimate kindness was to bestow freedom. Yet allowing masters to manumit slaves at will would create perverse incentives to free unproductive slaves. Consequently, the community at large would bear the costs of old, disabled, and rebellious former slaves. Roman emperor

Augustus worried considerably about this adverse selection problem and eventually enacted restrictions on the age at which slaves could be free, the number freed by any one master, and the number manumitted by last will (Watson 1987).

By the 1830s, most Southern states had begun to restrict manumission, often forcing newly freed slaves to leave the state. Some required former masters to file indemnifying bonds with state treasurers so governments would not have to support indigent former slaves. Some instead required former owners to contribute to ex-slaves' upkeep. Many states limited manumissions to slaves of a certain age who were capable of earning a living. By 1860, most Southern states had banned in-state and postmortem manumissions, and some had enacted procedures by which free blacks could voluntarily become slaves (Bourne 1998).

In addition to constraints on manumission, laws restricted other actions of masters and, by extension, slaves (Bourne 1998). Masters generally had to maintain a certain ratio of white to black residents upon plantations. Some laws barred slaves from owning musical instruments or bearing firearms. All states refused to allow slaves to make contracts or testify in court against whites. About half of Southern states prohibited masters from teaching slaves to read and write. Although masters could use slaves for various tasks and responsibilities, they typically could not order slaves to compel payment, beat white men, or sample cotton. Nor could slaves hire themselves out to others, although such prohibitions were often ignored by masters, slaves, hirers, and public officials. Owners faced fines and civil damages if their agent slaves caused injuries. In some jurisdictions, masters even paid for losses arising from willful acts (particularly theft) committed by their slaves. In this last respect, the law placed greater responsibility on owners of slaves than on masters of servants.

Slave Criminals

Slaves, like their free brethren, committed a host of crimes ranging from arson to theft to homicide. Other slave crimes in the US South included

violating curfew, attending religious meetings without a master's consent, and running away (Bourne 1998).

Southern states erected numerous punishments for slave crimes, including prison terms, banishment, whipping, castration, and execution (Bourne 1998). In most states, the criminal law for slaves (and free blacks) was noticeably harsher than for free whites; in others, slave law as practiced resembled that governing poorer white citizens. Particularly harsh punishments applied to slaves who had killed their masters or committed rebellious acts. Southern colonies considered these acts of treason and resorted to burning, drawing and quartering, and hanging.

Originally, many jurisdictions tried to spirit criminal slaves out of state. But Southern states quickly caught on and began to ban slave imports or check for criminal backgrounds of imported slaves. Transportation soon gave way to capital punishment for many slave crimes. Most states simultaneously implemented policies of compensating slaveowners for part of the value of executed slaves. These policies reduced incentives to conceal slave crimes or sell criminals to unsuspecting buyers. Yet lawmakers did not want people to abuse the state's generosity, so owners could not recover full value nor coerce slaves to confess.

Besides prohibiting coerced confessions, Southern states adhered to various other criminal procedures for slaves. Slave defendants had attorneys, in part because the alternative would have been self-representation. Slaves generally had jury trials, though obviously not of their peers. And slaves could testify against other slaves, although supportive testimony by one slave in defense of another carried little weight.

Modern Slavery

Rising British sentiment against slavery culminated in the *Somerset* case, which outlawed slavery in England in 1772. Britain and the United States abolished the international slave trade in 1808; Britain freed slaves in its colonies (except India) in 1833, with full emancipation in 1838.

Slavery in the United States officially disappeared by the end of the American Civil War in 1865.

Abolition came later elsewhere, often accompanied by an increase in other forms of servitude. Eastern Europe and Russia kept slavery alive into the late nineteenth century. In 1890, all major European countries, the United States, Turkey, Persia, and Zanzibar, signed the General Act of Brussels in an attempt to suppress slavery. Forty years later, an international labor convention acted to outlaw forced labor in the former Ottoman and German colonies. In 1948, the UN General Assembly declared that all forms of slavery and servitude should be abolished (Bush 1996).

Yet slavery in Southeast Asia, the Arabian peninsula, and Africa continued well into the twentieth century (Watson 1980; Lovejoy 1983; Klein 1993). Perhaps the saddest legacy of American slavery is that the system established to supply the New World with slaves also shaped society at home. Slavery within Africa burgeoned along with the Atlantic trade – in 1600 Africa had a minority of the world's slaves, in 1800 the overwhelming majority. The Great Scramble for Africa spread slavery further. Regrettably, the tragedy continues: Angolan slaves fought bloodily for freedom in 1961; Mauritania kept slavery legal until 1981; Nigeria still had slave concubinage in the late 1980s; and numerous African regions practice slavery today.

Some of the harshest forms of slavery have arrived only recently. Modern weaponry, increased population density, and mass communication and transportation technology have made it easy to capture and move purported enemies. The classic mechanism of modern slavery, patterned after the practices of Nazi Germany and the Soviet Union, is this: officials in power arrest suspected opponents of the current political regime, or those considered racially or nationally unfit, and throw them into forced-labor camps to work under terrible conditions. Unlike slaves in earlier societies, the unfortunates who landed in Nazi and Soviet concentration camps were not privately owned and traded in open markets. Rather, they served as property of the state, sometimes to be rented out to private interests.

Modern slaves consequently represent something much different than their historic counterparts. From preclassical times through the nineteenth century, masters typically viewed their slaves as productive investments, as book-keeping entries in their wealth portfolios, and as forms of valuable capital. Slaves in these circumstances could often count on minimal food, shelter, clothing, and time for rest and sleep. Not so for the “publicly owned” slaves of the twentieth century. Because these people were “acquired” at very low cost with public dollars and served primarily as political symbols, their masters had little incentive to care for them as assets.

To be sure, when Nazi Germany needed labor to fuel production of its war machinery, the country turned to the inmates of concentration camps. Likewise, the Soviets rounded up peasants to work on public projects and mineral extraction. Various regions across Africa, Asia, America, and Europe have done the same. Yet these sorts of “slaves” are often worth more dead than alive. Killing one’s political adversaries makes the state that much easier to run. Exterminating those labeled as unfit “cleanses” society – in a truly twisted sense of the word – and binds together the “chosen.” Accordingly, modern forms of mass slavery seem far different institutions than those of earlier times.

No type of slavery is benign, of course – despite the relatively better treatment of slaves held as productive investments, any form of slavery is at its core coercive. The behavior of American ex-slaves after abolition – who spent more time in leisurely pursuits and refused to work in gangs – clearly reveals that they valued their non-work time more highly than masters had and cared strongly about the manner of their work (Fogel and Engerman 1974; Fogel 1989). In effect, slavery is an economic phenomenon only because it neglects the costs to the slaves themselves.

Small Claims Litigation

► Class Action and Aggregate Litigations

Smith, Adam

Manfred J. Holler

Center of Conflict Resolution (CCR), University of Hamburg, Institute of SocioEconomics (ISE), Hamburg, Germany

Abstract

This entry discusses Adam Smith's theory of justice and its application to the law. Smith's theory of justice combines natural and acquired rights with a focus on commutative justice and economic reasoning. Core concepts are resentments, sympathy, the impartial spectator, and liberty. A possible conflict between liberty and economic expedience is illustrated by Smith's discussion of usury and bank regulation.

The Missing Book

In the closing lines of *The Theory of Moral Sentiments* (*TMS*), Adam Smith (1723–1790) states: “I shall in another discourse endeavour to give an account of the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society, not only what concerns justice, but in what concerns police, revenue, and arms, and whatever else is the object of law” (*TMS* 1982/

1759/1790, p. 342). However, Smith has never written this book that, given his deep insights into the working of the economy, could have become the pioneer work in what has become Law and Economics.

In the “Advertisement,” which introduces the sixth edition of *The Theory of Moral Sentiments* published in 1790, the year of his death, Smith refers explicitly to the above quote commenting: “In the *Enquiry concerning the Nature and Causes of the Wealth of Nations*, I have partly executed this promise; at least so far as concerns police, revenue, and arms. What remains, the theory of jurisprudence, which I have long projected, I have hitherto been hindered from executing, by the same occupations which had till now prevented me from revising the present work. Though my advanced age leaves me, I acknowledge, very little expectation of ever being able to execute this great work to my satisfaction; yet, as I have not altogether abandoned the design, and as I wish still to continue under the obligation of doing what I can, I have allowed the paragraph to remain as it was published more than thirty years ago, when I entertained no doubt of being able to execute every thing which it announced” (*TMS*: no page number). Thus, in order to explore Smith's concept of law and its economic analysis, we have either to rely on the references in his two published volumes, i.e., *The Theory of Moral Sentiments*, first published in 1759, and *An Inquiry into the Nature and Causes of the Wealth of Nations* (*WN*), first published in 1776/1777, or on the *Lectures on Jurisprudence* (*LJ*). The latter were compiled from notes of students who attended his lectures at Glasgow University during the sessions of 1762–1763 and 1763–1764. (This was in the years before Smith resigned from his chair of Moral Philosophy at Glasgow University and went on the grand tour of France as a tutor of Henry Scott, the young Duke of Buccleuch in 1764.) The close correspondence of parts of these lecture notes with material published in *TMS* and *WN* suggests that they are quite reliable reports of what Smith presented to his audience – as confirmed by Edwin Cannan who, in 1985, discovered “Lectures on Justice, Police, Revenue and Arms,” the first of the two

manuscripts which are edited as *LJ* by Meek, Raphael, and Stein (see *LJ* 1982/1762–1766, p. 5f). McCormick (1981, p. 244) confirms that in Division II of Part II of *LJ* “we find much of the theorizing of *The Wealth of Nations* already present in embryo.”

In the following, I will focus on the material of these three books. Sections “[Sympathy and the Impartial Spectator](#)” and “[Promises and Subsistence](#)” summarize Smith’s theory of justice and outline its building blocks: resentments, sympathy, and the impartial spectator. Section “[Selected Cases and Prominent Issues](#)” comments on Smith’s discussion of usury and bank regulation and illustrates a possible conflict between *natural liberty* and economic expediency. Some general remarks on Smith’s perspective on human nature conclude the paper. First, however, I will briefly clarify the concepts of jurisprudence, law, and justice and their relationship in Smith’s work.

Jurisprudence, Law, and Justice

Smith defines “jurisprudence” as “the theory of the rules by which civil governments ought to be directed” (*LJ*, p. 5) and, alternatively, “the theory of the general principles of law and government” (*LJ*, p. 398). “The four great objects of law are Justice, Police, Revenue, and Arms” (*LJ*, p. 398). “The object of Justice is security from injury, and it is the foundation of civil government” (*LJ*, p. 398). A “man” may be injured “as a man” and “as a member of a family” and “of a state” (*LJ*, p. 399). “As a man, he may be injured in his body, reputation, or estate” (*LJ*, p. 399). Smith considers the prevention of the body and the reputation from injury as natural rights, while he classifies the rights of estate to be acquired rights. The latter “are of two kinds, real and personal” (*LJ*, p. 399). Property falls into the category of real rights. Note that John Locke (1632–1704) claimed that man’s natural rights are life, liberty, and property. Inasmuch as acquired rights are defined by the society, Smith’s acknowledgment of property is weaker as it is not embedded in the human nature.

It is this combination of natural and acquired rights, and to justice, that distinguishes Adam

Smith from utilitarians like Jeremy Bentham and John Stuart Mill and from the core of modern scholars of Law and Economics who focus on efficiency to draw their conclusions. Smith’s reference to justice concurs with the observation, elaborated in Holler and Lerach (2010), that people are more concerned with justice than with efficiency. Of course, Smith accepts that the government can also intervene to achieve efficiency. His support for public education – “those for the education of youth, and those for the instruction of people of all ages” (*WN* 1981/1776/77, p. 723) –, the abolishment of slavery (because of inefficiency and not because of injustice), and the rigorous regulation of the banking sector are prominent examples. He is quite aware that government intervention is necessary to overcome the collective action problem (due to potential free-riding). The duty of “the sovereign or commonwealth is that of erecting and maintaining those public institutions and those public works, which, though they may be in the highest degree advantageous to a great society, are, however, of such a nature that the profit could never repay the expence to any individual or small number of individuals, and which it therefore cannot be expected that any individual or small number of individuals should erect or maintain” (*WN*, p. 723).

In addition, violations of justice are a strong argument to justify public action. Smith’s theory of justice builds on injuries and resentments. The corresponding feelings indicate violations. (“Resentment seems to have been given us by nature for defence, and for defence only. It is the safeguard of justice and the security of innocence” (*TMS*, p. 79).) As a consequence, in Smith’s theory “justice is necessarily conceived of as being corrective rather than distributive” (McCormick 1981, p. 247), i.e., the focus is on commutative justice (with a potential threat of punishment). However, whether a particular injury can prevail and triggers commonly shared resentments depends on the organization of the society. As Smith pointed out, if property does not exist or is of little importance, like in the society of hunters, then an unauthorized acquisition cannot result in injuries and resentments. But whether there is an injury and whether this injury triggers resentments

and whether these resentments are acknowledged as justified depends on the social value system as captured by the impartial spectator. That is, justice depends on the social development of the society reflected in its economic and moral conditions. Thus, “laws and legal institutions are an inherent part of the economy of a society and must be understood and explained as such” (MacCormick 1981, p. 254).

Sympathy and the Impartial Spectator

Smith’s impartial spectator “can be regarded as a ‘tool’ helping people to understand which actions, emotions and passions are appropriate. In order to gain approval and sympathy of the impartial spectator humans must exercise self-command to ensure that we are not overwhelmed by our passions” (Huber 2014, p. 11). It results from our potential to put ourselves in the position of others to see things from their point of view. In *TMS*, this potential is labeled sympathy, but today we would call it empathy. “Pity and compassion are words appropriated to signify our fellow-feeling with the sorrow of others. Sympathy, though its meaning was, perhaps, originally the same, may now, however, without much impropriety, be made use of to denote our fellow-feeling with any passion whatever” (*TMS*, p. 10).

It is not the passion of others which puts our sympathy in motion, but our *hypothetical* experience of being in the other person’s position. “Sympathy, therefore, does not arise so much from the view of the passion, as from that of the situation which excites it. We sometimes feel for another, a passion of which he himself seems to be altogether incapable; because, we put ourselves in his case, that passion arises in our breast from the imagination, though it does not in his from the reality. We blush for the impudence and rudeness of another, though he himself appears to have no sense of the impropriety of his own behaviour; because we cannot help feeling what confusion ourselves should be covered, had we behaved in so absurd a manner” (*TMS*, p. 12). Moreover, “as we have no immediate experience of what other men feel, we can form no idea of the manner in

which they are affected, but by conceiving what we ourselves should feel in the like situation” (*TMS*, p. 9). More drastically, Adam Smith observes: “We sympathize even with the dead, and overlooking what is of real importance in their situation, that awful futurity which awaits them, we are chiefly affected by those circumstances which strike our senses, but can have no influence upon their happiness” (*TMS*, p. 12).

Smith’s notion of sympathy differs substantially from David Hume’s notion as the following quotation shows: “When I see the effect of passion in the voice and gesture of any person, my mind immediately passes from these effects to their causes, and forms such a lively idea of the passion, as is presently converted into the passion itself” (Hume 1978/1739, p. 576). In Hume, it is the other’s *experience* and *passion* which triggers the fellow feelings, while Smith’s fellow feelings are due to the other’s *situation* or *action*.

There are immediate consequences of Smith’s notion of sympathy: the potential of self-evaluation and the pleasure of mutual sympathy. In the latter, it seems that Smith borrows from the everyday notion of sympathy. However, let us first look at the potential of self-evaluation. Smith (*TMS*, p. 109) observes that the “principle by which we naturally either approve or disapprove our own conduct, seems to be altogether the same with that by which we exercise the like judgements concerning the conduct of the other people. We either approve or disapprove of the conduct of another man according as we feel that, when we bring his case home to ourselves, we either can or cannot entirely sympathize with the sentiments and motives which directed it. And in the same manner, we either approve or disapprove of our own conduct, according as we feel that, when we place ourselves in the situation of another man, and view it, as it were, with his eyes and from his station, we either can or cannot entirely enter into and sympathize with the sentiments and motives which influenced it (*TMS*, p. 109).” Smith argues: “We can never survey our own sentiments and motives, we can never form any judgement concerning them; unless we remove ourselves, as it were, from our own natural station, and endeavour to view them as at a certain distance

from us. But we can do this in no other way than be endeavouring to view them with the eyes of other people, or as other people are likely to view them.” Smith concludes: “We endeavour to examine our own conduct as we imagine any fair and impartial spectator would examine it” (*TMS*, p. 109).

We could argue that people follow this pattern and that is why sympathy allows for self-evaluation and the evaluation of others. However, Smith gives a further argument: “In this...as well as in every other emotion, passion, and habit, the degree that is most agreeable to the impartial spectator is likewise most agreeable to the person himself...” (*TMS*, p. 262). As we are social beings, we do not ignore the judgment of others. On the contrary, we strive for their appreciation and are therefore willing to change our habits and our behavior such that others can agree with them. From the conduct of sympathy, we derive an impartial spectator, “a man within the breast,” that helps us to evaluate, to control, and to restructure our behavior. It influences our conduct without identifying the evaluators, i.e., their judgments or, more specifically, their preferences or value systems.

However, the impartial spectator is a rather complex creature when applied to other persons. There is a “first-person-plural perspective I share with all others to whom my judgment is implicitly addressed” (Darwall 1999, p. 160) and, secondly, I put myself into the shoes of the person being judged by me. “When I make a moral assessment of someone’s motive or feeling, according to Smith, I express a sympathy with it that I expect any one (of us) to share. I impartially project myself into that person’s standpoint, not as myself but as any of us, and (attempt to) judge what any of us would be moved to do or feel if in that person’s shoes” (Darwall 1999, p. 160).

The construct of an impartial spectator and the self-evaluation by means of sympathy presuppose that there is some common platform of experience in this society. Not friendly fellow feelings trigger the “pleasure of mutual sympathy” (*TMS*, p. 262) but the fact that sympathy can work because of the common experience which the members of a society share. The common experience creates the familiarity, paired with universality, on which

the impartial spectator functions (Witztum 1997; Leroch 2008). “Man, say they, conscious of his own weakness, and of need which he has for assistance of others, rejoices whenever he observes that they adopt his own passions because he is then assured of that assistance; and grieves whenever he observes the contrary, because he is then assured of their opposition” (*TMS*, p. 13f). If our passions (and thereby our evaluations and judgments) are confirmed by others, then we feel good, although the passions as such can result from sorrows and pain.

Smith’s moral sentiments require a “moral community of common understanding and experience” (Darwall 1999, p. 160). Given such a community, it seems that, at least in the short run, we have no control of the pleasure of sympathy and the pain of opposition as they “are always felt so instantaneously, and often upon such frivolous occasions, that it seems evident that neither of them can be derived from such self-interested consideration...” (*TMS*, p. 14). Obviously, the range of sympathizing is limited and so is the reach of moral communities. (See Holler and Leroch (2008) for a discussion.) As a consequence, “an irreducible plurality of virtues and corresponding norms” results (Sturm 2010, p. 269). It is a function of the law to propose general (obligatory and universal) standards for a society and to implement them.

Promises and Subsistence

The domain of the impartial spectator and its generalization also decides on whether we observe an injury, or not. In *LJ*, Smith argues that a contract implies a promise and “the promise produces an obligation, and the breach of it is an injury” (*LJ*, p. 472). However, the “breach of a contract is naturally the slightest of all injuries...in rude ages crimes of all kinds, except those that disturb the public peace, are slightly punished, and society is far advanced before a contract can sustain action or the...breach of it to be redressed” (*LJ*, p. 472). According to Smith the probability of injury involved in the breaching of contracts is a result of the economic

environment, the social interaction, and the rationale of the agents: “When a person makes perhaps twenty contracts in a day, he cannot gain so much by endeavouring to impose on his neighbour, as the very appearance of a cheat would make him lose. When people seldom deal with one another, we find that they are somewhat disposed to cheat, because they gain more by a smart trick than they can lose by the injury which it does their character” (*LJ*, p. 538f). Note that this argument concurs with the Folk Theorem, one of the major results of modern game theory for iterated prisoners’ dilemma situations with multiple players. Tullock (1985) applied this model to corroborate Adam Smith rationale.

Does injury extend to failures to achieve subsistence and result in sentiments that trigger redistribution? Witztum (1997, p. 255) argues that Smith “would agree with considering the failure of distributing subsistence as a violation of justice in its commutative sense (i.e., requiring positive reprisal)” as it “will create harm and injury, not only through labourer’s frustrated expectations, but through physical and mental hardship as well” (p.256). In his paper “Adam Smith on justice and distribution in commercial societies,” Salter (1994) further elaborates this argument.

Ziegler (2014, p. 41) argues “that, for Smith, distributive justice exceeds the instrument of transferring benefits – he considers it to be purely complementary and not a necessity. The system of natural freedom and freedom of trade that he propagates also provides a certain state of distributive justice that is accompanied by an increase in wealth for all individuals.” Smith’s definition of justice implies abstaining from taking what others already rightfully and legally possess. However, what is meant by rightfully and legally is subject to the impartial spectator. Given the violation of subsistence and the sentiments which it arouses, Witztum (1997, p. 248) concludes that “both familiarity and universality of such sentiments in the age of commercial society would have guaranteed the impartial spectator’s approval of their resentment and would demand an enforced recompense.” Witztum and Young (2006) claim that the right to subsistence is included in Smith’s extended notion of justice.

One should add that Adam Smith was quite aware that subsistence by appropriating the fruits of labor is not guaranteed even in societies of some surplus with the consequence of “destroying a great part of the children which their fruitful marriages produce” (*WN*, p. 98). Consequently, Witztum (1997, p. 259) concludes, “. . . such an organisation of society will clearly be unjust.” One might add, especially “when masters combine together in order to reduce the wages of their workman. . . Were the workmen to enter into a contrary combination. . . the law would punish them very severely” (*WN*, p. 158). In Adam Smith’s writings we do not find a recipe of how to overcome this injustice (if not by economic growth which makes labor scarce and pushes wages above subsistence) – although such violations of impartiality “earn the resentments of the impartial spectator, and so fail the test of justice” (Buckle 2013, p. 100).

An implication of Witztum’s reasoning is that a possible redistribution can be derived from commutative justice (and not distributive justice) if the impartial spectator is universal enough to support such a policy. However, in an earlier paper (Holler 2006), I argued that the impartial spectator is of local character, as it is based on the reference to family members, friends, members of the community, etc. In general, the various groups of a society have quite distinct impartial spectators, implying different modes of behavior (while the organization of the market economy is rather general, even transgresses national borders). This raises the question of consensus: Is there an impartial spectator that considers society as an agent and the failure to achieve subsistence as its responsibility? The social security systems of Western Europe no longer accept unemployment as individual fortune. Moreover, there is a rather lively discussion of basic income which could be considered as the consequence of an expansion of the impartial spectator.

Selected Cases and Prominent Issues

In many societies usury seems to be a challenge to the impartial spectator as well as economic reasoning (and liberty). In many cultures and legal

systems, the interest on credits has been prohibited by civil, penal, or canonical law. However, as Smith (*WN*, p. 356) observes, this “regulation, instead of preventing, has been found from experience to increase the evil of usury; the debtor being obliged to pay, not only for the use of the money, but for the risk which his creditor runs by accepting a compensation for that use. He is obliged, if one may say so, to insure his creditor from the penalties of usury.” Smith favors a regulation that fixes an upper limit to the interest and thus bans usury. He argues that this rate “ought always to be somewhat above the lowest market price, or the price which is commonly paid for the use of money by those who can give the most undoubted security.” If such a limit does not exist, a “great part of the capital of the country would thus be kept out of the hands which were most likely to make a profitable and advantageous use of it, and thrown into those which were most likely to waste and destroy it. Where the legal rate of interest, on the contrary, is fixed but a very little above the lowest market rate, sober people are universally preferred, as borrowers, to prodigals and projectors. The person who lends money gets nearly as much interest from the former as he dares to take from the latter, and his money is much safer in the hands of the one set of people, than in those of the other. A great part of the capital of the country is thus thrown into the hands in which it is most likely to be employed with advantage” (*WN*, p. 357). Obviously, the consequences of usury constitute a version of adverse selection, i.e., of market failure: Without a legal upper limit, the interest rate could reach such a level that only those will borrow money who do not intend to pay back the loan, or in the end will be unable to pay the interest while “sober people” will be crowded out – of course, with negative effects to overall economic performance.

Note that Smith does not talk about justice, when arguing against usury. It is a matter of economic reasoning, i.e., taking efficiency into account, that he uses to suggest its banning. Economic reasoning is also his justification for tight regulation of the banking sector, even at the cost of a violation of natural liberty. “To restrain private people, it may be said, from receiving in

payment the promissory notes of a banker, for any sum whether great or small, when they themselves are willing to receive them, or to restrain a banker from issuing such notes, when all his neighbours are willing to accept of them, is a manifest violation of that natural liberty which it is the proper business of law not to infringe, but to support. Such regulations may, no doubt, be considered as in some respects a violation of natural liberty” (*WN*, p. 324). However, the analysis of the banking sector told him that it needs strict regulations in order to limit the circulation of bank notes and to avoid crises that are disastrous to the economy and thus for the country. He concludes: “But those exertions of the natural liberty of a few individuals, which might endanger the security of the whole society, are, and ought to be, restrained by the laws of all governments, of the most free as well as of the most despotical. The obligation of building party walls, in order to prevent the communication of fire, is a violation of natural liberty exactly of the same kind with the regulations of the banking trade which are here proposed” (*WN*, p. 324).

Smith “defends the system of free trade, but he does so because of the benefits it delivers, not because of the inviolability of individual self-interest” (Buckle 2013, p.100). If natural liberty is considered a subject of natural rights, then, in the case of regulating banking, Smith proposes a violation of natural right in favor of economic efficiency and the “wealth of a nation.” The regulation of the banking sector, as proposed by Smith, is an illustration of *second-best liberalism*. “Creating and maintaining the conditions for the system of natural liberty tends to imply a *constant challenge*, including a set of complex tasks, institutions and practices” (Sturm 2010, p. 276). This challenge may necessitate putting a limit to liberty.

However, Smith also observes the economic forces of self-interest at work when it comes to the implementation of the law. Here is an example. “The landlord and tenant, for example, might jointly be obliged to record their lease to a public register. Proper penalties might be enacted against concealing or misrepresenting any of the conditions; and if part of those penalties was to be paid to either of the two parties who informed against

and convicted the other of such concealment or misrepresentation, it would effectually deter them from combining together in order to defraud the publick revenue. All the conditions of the lease might be sufficiently known from such a record" (*WN*, p. 831).

On the other hand, Smith is quite aware that the law does not always contribute to the common good, and in some cases, it simply fails as it cannot be executed. "People of the same trade seldom meet together, even for merriment and diversion, but the conversation ends in a conspiracy against the publick, or in some contrivance to raise prices. It is impossible indeed to prevent such meetings, by any law which either could be executed, or would be consistent with liberty and justice. But though the law cannot hinder people of the same trade from sometimes assembling together, it ought to do nothing to facilitate such assemblies; much less to render them necessary" (*WN*, p. 145). In Smith's time assemblies were rendered necessary because of a regulation "which enables those of the same trade to tax themselves in order provide for their poor, their sick, their widows and orphans" (*WN*, p. 145). Today, these obligations do no longer exist, but it seems that those of the same trade still meet.

On Human Nature

There is hardly a more controversial writer in the history of economics and the social sciences than Adam Smith inasmuch as very different "social religions" identify their roots with his work. By many he is hailed as a prophet of free markets while others point to his elaborate moral theory and the fundamental social dimension of his thought (and life). One might argue that this is due to the fact that one group studied *TMS*, while the other had his *WN* at their bedside. It is very likely that only a very small percentage of those who refer to Adam Smith to sell their ideas about how to improve the world have actually read either of these books; and certainly very few have read both – let alone having read his correspondence or *LJ*.

However, it might be superficial to blame the potential readership for not adequately accomplishing its duty of reading when it comes to Adam Smith. If there is an obvious shortcoming, then there could also be a reason for this. A possible answer to this puzzle could be that Adam Smith proposed at least two "models of man:" the self-interested individual that forms the core of his economic theory, the dominant character in the *WN*, and the moral agent controlled by the sympathy, sentiments, and impartial spectator, introduced in his *TMS*. It has been argued that the latter does perhaps not reach far enough to evaluate the outcome which corresponds to his economic theory from a *social* point of view. (See the issue of subsistence, discussed above.) Human nature could be the source of this shortcoming: Sympathizing seems to be biased. "It is because mankind are disposed to sympathize more entirely with our joy than with our sorrow, that we make parade of our riches, and conceal our poverty. Nothing is so mortifying as to be obliged to expose our distress to the view of the public, and to feel, that though our situation is open to the eyes of all mankind, no mortal conceives for us the half of what we suffer. Nay, it is chiefly from this regard to the sentiments of mankind, that we pursue riches and avoid poverty" (*TMS*, p. 50).

But there is also "the desire of bettering our condition, a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave. . . there is scarce perhaps a single instant in which any man is so perfectly and completely satisfied with his situation, as to be without any wish of alteration or improvement, of any kind" (*WN*, p. 341).

Smith refers to this desire to explain the motivation for the accumulation of capital by means of saving. It represents a disposition of "man" which follows him throughout his life, "though generally calm and dispassionate." However, there is another motivation for the accumulation of capital: to become *rich*. "In Smith's view. . . man is inspired in commercial society to pursue the rewards of sympathy and the approbation through the means of acquiring wealth and property at the

expense of seeking sympathy through virtuous behaviour. The pursuit of wealth thus tends to crowd out virtue as a means to be taken notice with sympathy” (Verburg 2000, p. 38). The argument here is that there is no theory of social justice which permits us to evaluate the overall economic outcome (see Huber 2014). The implications and consequences of the economic system narrow down the application of the individualistic moral theory embedded in the impartial spectator and corrupt its standards. It seems that there is no “Adam Smith problem,” as was widely discussed in the German nineteenth-century literature (see Sturn 2010), but a problem in the human nature: being very general and broad when it comes to economic efficiency and rather specific and narrow when thinking in terms of justice.

Acknowledgments I would like to thank Heinz Kurz, Barbara Klose-Ullmann, Martin Leroch and Rigmor Osterkamp for their helpful comments.

Social Damage

Stephan Marette

UMR Economie Publique INRA, Paris, France

Definition

The social damage is a damage suffered by the society as a whole because of corruption, bad use of public money, or wrongdoing. The social damage includes the stolen assets, the wasted money that could be alternatively spent by the society, and also ethical dimensions, like moral damages or violation of trust regarding public values.

A Nascent Concept

The social damage is a damage suffered by the society as a whole and differs from the private

damage that is incurred by a private entity. The possibility to pay a compensation to the victim who is the “society as a whole” recently emerged.

The social damage was directly mentioned in the settlement agreement related to corruption between Alcatel and the Costa Rica. In 2010, this French firm agrees to compensate for the damage coming from bribes and caused to citizens. Alcatel paid US\$10 million for compensating this social damage. This settlement does not impede additional compensations to other victims, like private compensation to ousted competitors (Olaya et al. 2010).

A lot of attention was given to this settlement agreement in Costa Rica by people or organizations who search to fight corruption (see Olaya et al. 2010 for details). The social damage was compensated in Costa Rica, because of an explicit legislation mentioning this precise topic, which is a very important point for implementing legal decision and compensation. In a 2010 workshop (in page 2 in IACC 2010), Mr. Eckert, a German judge, mentioned “that he always aimed at compensating social damages. However, he also made it clear that Germany had no definition of social damage in its penal code. Judge Eckert concluded by stating that there is a need for rules on social damage.”

The absence of explicit legislations defining social damages in many countries limits the possibility to effectively compensate society for this damage. However, the *United Nations Convention Against Corruption* signed by many countries in 2004 emphasizes the right to restitution of stolen assets to society (see United Nations 2004). This is a clear stage toward the recognition of the social damage, even if this concept is not explicitly mentioned in the convention. This nascent concept could be used for deterring firms and individuals of wrongdoing related to public goods.

An Economic Interpretation

As this concept is nascent regarding the victims’ compensation and not fully defined in many legislations, we turn to the economic approach to

help clarify this concept. The social damage can be accurately detailed by using the concept of public goods.

While private goods are traded in markets with prices reflecting quality levels, public goods are non-excludable and non-rival in consumption. As a consequence, it is often optimal for agents to let others contribute and benefit from this public good without contributing to its production or financing. The payoff structure reflects a prisoner dilemma trade-off coming from game theory, such that the dominant strategy is to invest nothing (or cheat) in the public good if they expect enough other participants decided to invest (or being honest). Public goods are rife and they include all social values related to social damages such as trust, honest administration, legitimacy of institutions, and fair competition.

The concept of public good may help to value the economic loss coming from a social damage, even if this is relatively difficult. For the corruption case, the economic loss can be estimated by comparing the collective utility for a situation with the social damage compared to the collective utility without the social damage. A so-called equivalent variation for maintaining a collective utility without social damage compared to a case with corruption could be estimated. New techniques like lab experiments focusing on corruption could give a social value relative to the absence of corruption, by extrapolating the elicited value of a small group of people attending the experiment to the whole population (see Bobkova and Egbert 2012). However, the empirical estimate of such a loss is difficult because of the nonmarket nature of public goods with no observable prices that help determine social values.

The other contribution of the economic approach consists in evaluating various legal and regulatory measures, for limiting the social damage and understanding agents’ incentives to avoid behaviors leading to social damages. This particularly raises the question of the optimal effort and sanction for deterring potential wrongdoers. When the social damage is not recognized by a legislation and de facto not compensated, there is an incentive to lean toward bad behaviors and an underinvestment in virtuous practices.

Eventually, an overlooked aspect of having private damages and social damages to be compensated for a same wrongdoing such as corruption is the risk of accumulating reparations. This accumulation of compensations may reinforce the judgment-proof problem, for which the potential defendant at the origin of damages is financially insolvent and unable to fully cover compensations. The judgment-proof problem modifies incentives to have virtuous behaviors compared to the socially optimal level maximizing the welfare of the whole economy (see Shavell 2005). In other words, the judgment-proof problem may lead some firms to adopt corruption behavior, while the society would be better off without any corruption behavior.

The concept of social damage is important for preventing cheating and bribes. This is also a fragile concept because the social damage is relatively hard to measure.

Standard Cost Model

Wolfgang Weigel

Faculty of Business, Economics and Statistics,
Department of Economics, Joseph von
Sonnenfels Center for the Study of Public Law
and Economics, Vienna, Austria

Definition

The Standard Cost Model is a tool for the reduction of administrative burdens of businesses. It rests on a fairly simple technique of identifying such activities which are found unnecessary by experts and thus have the potential of savings on expenses. The economic idea behind its application is that means are unleashed which can be used more efficient and effective, thus fostering growth. However, the tool also has a couple of shortcomings, which presently give rise to the development of a new generation of SCM (SCM 2.0).

Introduction

The Standard Cost Model (SCM) is a widely used remedy against certain kinds of red tape. It belongs to the family of devices for less and better regulation, nowadays handled under the more handy label “smart regulation” (see: <http://www.oecd.org/regreform/policyconference/46528683.pdf>.) This model aims at identifying and measuring the administrative burdens of businesses. Thus, it is an indispensable prerequisite for steps towards the reduction of administrative burdens. This is

Wolfgang Weigel was retired.

partly accomplished by simplifying obligations to comply with regulatory demands of governments and partly by checking the possibilities of abolishing them altogether. One rationale behind this measure is the gain of resources, which can be spent more productive, as suggested with respect to the annual World Bank report “doing business,” where objective measures are provided for local firms regarding the intensity of regulation (see: The World Bank (<http://www.doingbusiness.org>)).

Originally developed in the Netherlands as “MISTRAL” (Measuring Instrument Administrative Burden, where burden in Dutch is Last) between 1992 and 1994, it is by now used under its more popular label in more than 20 states. It forms part of a set of four instrumental tools for scrutiny of legal rules, where the other tools are cost benefit analysis, cost effectiveness analysis, and multicriteria analysis (asking what kind of action produces the largest expected utility).

This note provides an overview of the methodology, primarily focusing on businesses but also pointing out the attempts to apply the SCM to households. It starts with a review of the model, addresses problems and shortcomings and the way towards a SCM 2.0, followed by a short outlook.

Review of the Standard Cost Model (SCM)

The SCM aims at identifying, measuring, and assessing the cost accruing to businesses when complying with administrative demands. Such costs typically arise from obligations to provide information to a central authority (the federal government, say) or the public (customers, for example).

At the beginning, the outline of the model will be reproduced following the International Standard Cost Model Manual (<http://www.administrative-burdens.com/default.asp?page=122>, January 24th, 2008, 11.27).

In order to accomplish this task, a couple of charts will be reproduced. The rationale behind this is to give an impression of the distinction

between such costs, which have to be borne due to indispensable institutional regulations (the most prominent examples being taxes and fees) and those costs which are “administrative burdens” (the said obligations to provide information).

The first chart provides a general overview.

Chart 1: The different costs of regulation to businesses

The content of the entries is as follows.

Direct financial costs comprise all obligations for financial flows to government. The outstanding examples are taxes. However, businesses may also be obliged to fees for receiving certain permits, which are also seen as direct financial charges according to the International Standard Cost Model Manual (p. 6).

Compliance costs are all other costs with the exception of those arising from long-term structural consequences. Compliance costs can be broken down into:

- Substantive compliance costs, which contain, for example, the installation of filters or physical facilities in order to meet workplace regulations such as safety devices.
- Administrative costs, which are in the focus here. They accrue from the obligation to report about safety installations, say, or annual reports on the accomplishment of environmental standards (and many more, of course).

The latter have to be examined more closely. More specifically, administrative burdens have to be distinguished as the subset of administrative costs, which is relevant here (see Weigel 2008).

Again, the gist can be captured in a chart.

Chart 2:

While the distinction of the contents of the boxes should be evident, there is one caveat. It may be the case that some of the “administrative burdens” could be continued as deliberate administrative activities, even if the obligation were removed (such as information, which ultimately is part of a marketing strategy). However, it is very hard and laborious to make that distinction *ex ante*. It therefore is neglected.

In the next step, again making use of a chart, the way is outlined, how administrative burdens are calculated.

Chart 3:

In preparing the basis for the calculation of the cost of administrative burdens, a sophisticated

procedure is elaborated, which includes the solution of problems such as the assignment of some Information Obligations (IO) to the source, which can be European law, national law, or local regulations. Only norms of EU and the national level are taken into account (See International Standard Cost Model Manual, p. 27). Another detail worth mentioning here is whether an IO was met by the firm or had been outsourced (See International Standard Cost Model Manual, p. 35).

The whole procedure is described in detail in the International Standard Cost Model Manual (pp. 20 *passim*), and the interested reader is referred to this source.

The most important and controversial step in the course of investigations is that of determining the time and money cost at going wage rate for the cost per administrative activity. They are not raised firm by firm but rather standardized assuming a “normally efficient” firm.

The idea behind this notion is that in lieu of the time consumed for IOs as collected for each firm in the sample a representative value is chosen, which then is valued at the going wage rate (if performed by an employee, but disregarded if outsourced!) in order to arrive at the cost P according to chart 3. The core idea here is that outliers are not included in the calculation. To illustrate: some IO might take 10 min time in firms A, B, and C, whereas it takes 30 min in firm D. Then, the representative value is 10. If there was an additional firm in the sample with a performance of 2 min, this would also be excluded. However, in cases where the spread between best and lowest value becomes very large the reasons might be scrutinized by further interviews. Still the findings will not enter the outcome, since this will be taken from the average, but neither from the high nor the low performer!

Firms, which are close to the representative figure, are consequently labelled as “normally efficient.” Note that the further calculations rest only on data for “normally efficient” firms.

Surveys are carried out by experts. Following the procedure in Austria as an illustrative example experts are supported (and controlled) by special teams which are installed for each of the

ministries, for which information requirements have been identified from the law.

When the calculation was first made in Austria, for example, 561 legal provisions were identified containing 5687 information obligations. The total administrative burden was calculated at 4.6 billion € or 1.6% of GDP!

The target then was set at bringing the burden down by 25% by identifying and removing appropriate IO. Based on the insights from the World Bank's "Doing Business," the measure is supposed to push the growth of the economy considerably.

Properties, Shortcomings, and the Path Towards SCM 2.0

The following features of the SCM need to be stressed. They partly give rise to criticism and subsequently to the development of SCM 2.0, which is under way.

The first and foremost problem with the model is the implicit assumption that all legally mandated information obligations are met, both to the required extent and quality. To the contrary, large parts of the economics of property law, tort law, contracts, governance, environmental law, the economic theory of bureaucracy, and specifically the theory of corruption are based on the assumption that the agents seek their advantage under given constraints, boiling down to the neglect of regulatory demands. From the viewpoint of the regulators, no enforcement and hence no enforcement costs are taken into account. Thus, the actual administrative burdens may be lower than those calculated.

It must not be overlooked that the information obligations under scrutiny are not the only cost accruing to businesses from regulatory demands. They might face considerable compliance costs, which are rooted in overly complicated regulations, "transaction costs" of meeting the requirements through outsourced means such as expertise to appropriately understand demands and economize on them. Such considerations imply that the exercise of reducing administrative

burdens falls short of the objective. One reason could be the difficult wording or ambiguities in laws.

Another important issue relates to the rationale for regulation. In theory at least, it is rooted in some perceived market failure. Of course, regulatory requests can at the same time be a consequence of rent-seeking or simply an outflow of power. So the crucial step of deciding which IO are to be removed must not be carried out without scrutinizing the reasons for the existence of the IO at hand.

There are also problems with the "normally efficient firm". Since the extreme values of time consumed in performing IOs (both highs and lows) are ruled out by definition, distortions of the findings caused, e.g., by the presence of substantial X-inefficiency (Leibenstein 1966) within firms are not taken into account. But cases, which could serve as best practice, are also disregarded. Moreover, the way in which firms handle their IOs are also of interest. Do they employ special staff or is it done as additional business, which in turn implies that the person capable of such additional business may have comparatively high qualification.

Both points are relevant for the overall purpose of the entire exercise: to create a boost for the economy. With X-inefficiency, the relief will not become effective, since the firms by definition are not on their production possibility schedules; they may not even know them.

Likewise, firms upon relief from IOs may save on staff and not necessarily use the saved means for expansion. So the intended effects of the whole undertaking are quite uncertain.

More general objections are the following:

- In order to effectuate the objective of the SCM, it is not just necessary to enable firms to save on administrative costs but to keep them (or bring them back to be) competitive. Without such focus, the tool will create windfall profits for firms only.
- So it is not just the relief from burdens but rather the market structure, which is at stake. This in turn requires a more general focus, which includes the quest for regulation, an

issue, which is not covered by SCM, as has been mentioned earlier.

- A more general view such as that taken by Regulatory Impact Assessment (RIA) would head for maximizing the net benefits from regulation, where benefits are plotted against regulatory costs at large. SCM instead concentrates (and proofs its use) on areas of high inefficiency due to said administrative burdens only.

For the sake of completeness, it ought to be pointed out that after the first round of applications considerable effort was spent on finding out weaknesses and shortcomings in the handling of the procedure. That is to say, the institutional framework and the organization of handling the SCM was also under scrutiny (see Nijsen et al. 2009; Torriti 2007).

Thus, proponents of the SCM are fully aware of the shortcomings in what is now labelled “SCM 1.0” and therefore move towards SCM 2.0.

It is worth noting that attempts are under way to extend the SCM to private households. However, the calculus of cost per activity times frequency is hardly applicable. So research concentrates on effort in hours as well as direct costs. Moreover, qualitative aspects are considered, presently in a pilot study for Austria, for example, with the top 100 information obligations for households.

Outlook

The Standard Cost Model is a comparatively straightforward tool for the reduction of certain administrative burdens, which are consequence of governmental regulatory obligations to businesses. Given its relative simplicity, it has quickly become quite popular among governments. Said administrative burdens are quite high according to calculations in a large number of OECD member-states. To illustrate: the total burden for Austria was calculated to be 4.3 billion € (1.66% of nominal GDP). This burden is equal to those found in the UK (1.5%) and Denmark (1.9%), lower than that in the Netherlands (3.7%) but higher than that in the USA (about 1%),

according to a Review of the World Bank Group. To make these means accessible for productive purposes contains a substantial potential for economic growth (according to “Doing Business,” actual year).

The problem with what nowadays is labelled SCM 1.0 is that it may not provide accurate figures, since it rests on assumptions and procedures, which very likely lead to an overestimate of the gains. Moreover, it does not question regulation at large and obviates cost-benefit analyses, which are at the core of the more comprehensive approach of regulatory impact assessment (see Wegrich 2009).

Nowadays, these shortcomings are well understood and a SCM 2.0 is under way, which is to overcome the main sources of dissatisfaction with the first generation of the model.

State Aids and Subsidies

Régis Lanneau

Law School, CRDP, Université de Paris Nanterre,
Nanterre, France

Abstract

The power to give money is apprehended, in legal terms, through the notions of subsidies and state aids. In a conventional approach of state aids and subsidies control, it is because they have a potential effect on the competitive position of economic and create some trans-frontiers spillovers that these “spending” are or should be controlled at a supranational level. This entry will inquire into the rationale and limit of state aids control.

“The state – the machinery and power of the state – is a potential resource or threat to every industry in the society. With its power to prohibit or compel, to take or give money, the state can and does selectively help or hurt a vast number of industries” (Stigler 1971). The power to give money is apprehended, in legal terms, through the notions of subsidies (WTO, SCM agreement) or state aids (EU law), even if this latter notion is broader than direct subsidies (or financial contribution in WTO’s meaning even if this wording remains unclear, Wilcox 1999). Indeed, article 107 TFUE is characterizing state aids as “any aid granted by a Member State or through State resources in any form whatsoever which distorts or threatens to distort competition by favouring certain undertakings or the production of certain goods [...], in so far as it affects trade between Member States.” Case law is thus not restricting state aids to subsidies narrowly understood and includes loans, direct investment, tax reliefs, preferential tariffs, tax remission, free allocation of pollution rights, etc. Moreover, and in a conventional approach of state aids and subsidies control, it is because they have a potential effect on the competitive position of economic agents (because they are providing a benefit or an advantage) and create some trans-frontiers spillovers

(affect trade between member states) that these “spending” are or should be controlled at a supranational level. To strengthen this logic, both legal definitions are also including the idea of “specificity” (WTO) or “selectivity” (EU law) to distinguish between general measures (which are legal) and these legal categories.

In the remaining of this article, I will only focus on state aids, even if the framework which will be developed could largely be transposed to WTO’s subsidies (see Sykes 2003). Moreover, I will not provide a legal and economic analysis of each of the elements of qualification (advantage, using state resources, selectivity, affecting trade between member states) (for more details, see Röller et al. 2008). They are no doubt prone to interpretation (as ECJ case law would testify, see also European Commission 2008), and an economic analysis could provide some sound rationale at this level; nevertheless, a general framework for understanding state aids is a prerequisite for such analysis. This framework revolves around two questions. First, why do we need to control them at a supranational level? Second, how to design state aids control to enhance efficiency?

Why Should We Control State Aids at a Supranational Level?

If governments were only intervening in the economy to enhance efficiency (through the reduction of transaction cost and the reduction of market failures) and if that intervention would not lead to negative spillovers, controlling for state aids at a supranational level would not make sense since it will not allow for efficiency gains (quite the contrary actually because of the administrative costs it incurs). This does not mean that government failures are, by themselves, a sufficient reason to control for state aids at a supranational level (A) (even if, in some model, it would make sense; Dewatripont and Seabright 2006). The best rationale for this control seems to be trans-frontier spillovers (B) (Besley and Seabright 1999). Nevertheless, even in that case, only some spillovers should be targeted. Of course, both rationale could be and are combined to justify the actual system.

Limiting Rent-Seeking Rationale?

It is true that without any mechanism for controlling state aids, nothing, except maybe voters, would prevent governments to waste their resources to favor some successful interest groups, and there are few doubts that government spending decisions are not always promoting efficiency (Neven and Roller 2000). Knowing that it is possible to extract a rent through lobbying, interest groups will try to earn some “aids” and might even adapt their behavior even before any aid is granted. This rent-seeking approach of state intervention is quite classic (Stigler 1971; Posner 1974; Peltzman 1976) and largely documented (Persson and Tabellini 2000).

The mere prohibition of state subsidies or aids through, for example, a constitutional provision, would of course be inefficient since they are sometimes desirable; but a control at the level of each state – providing the possibility to use or design an efficient institution to achieve such end – could have made sense if the purpose is only to reduce rent-seeking. A control at a supranational level would not then seem to be required to limit the inefficiency effects of rent-seeking; after all, why would a supranational level institution be less prone to failure than national institutions? It is true that a supranational control would, in theory, insulate granting aids from political cycles (and, e.g., overspending before elections) but this rationale does not seem to be sufficiently strong to justify for a control. Indeed, in that case, the controlling institution will be perceived as “blocking” national will and might then be criticized for being technocratic – this could be privately welcomed and publicly criticized by national politicians; it is only if it appears that this institution is blocking more bad than good projects that it could earn some legitimacy (even if nationalist would, even in that case, criticize the institution as being anti-democratic). Moreover, it would be “too easy” to require another level of control to overcome known political failures.

It is true that if a supranational institution enjoys some expertise in this domain, using it could reduce administrative costs, but, once again, this logic is not sufficiently strong to justify for a systematic control of state aids.

Trans-frontier Negative Spillovers?

To justify the intervention of a supranational level, the effect of the state aids should not be strictly national (a parallel could be drawn using the subsidiarity model provided by Cooter 2000). If the aid is creating positive spillovers, it is unlikely to be criticized internationally; only perceived (but not always “real”) negative spillovers will then be targeted by litigants and institutions in charge for the control of state aids. Moreover, the potentially affected parties should agree to cooperate (which is the case for EU or WTO members; quite strangely, no control of state aids exists in the USA); otherwise, no supranational entity could exist.

There is little doubt that aids could be strategically used by states to attract companies and all their associated benefits in terms of taxes, employment, and more broadly economic dynamism. It would then be logical that, in the absence of such control, governments could compete using state aids (but not only). If governments were spending their resources efficiently, such competition would enhance welfare: the mere fact that a government is ready to spend more reveals that national spillovers will be higher than in other locations. This situation of course assumes that the national spillovers are varying across jurisdictions and that using the taxation system is not too costly. Note also that if the use of the tax system were zero, state aids would only have distributional effects and no efficiency effects (Spector 2009). Nevertheless, the use of the taxation system is costly so that transferring money to a firm costs more than the benefits the firm is receiving. If state aids were controlled, states would not waste resources to attract firms and avoid the prisoner’s dilemma game of subsidy races. Moreover, the distortions produced by an increase in taxes to insure this subsidy race are undesirable (Collie 2000).

State aid control is often justified by distortion of competition. Nevertheless, if the products are sufficiently homogenous and the market competitive, it is difficult to understand how its costs for competition would be higher than its benefits for consumers since it is unlikely to affect the market price in the long run. In an oligopolistic

structure, things could be different since the aid could lead to predatory pricing or end up with a merger between the recipient of the aid and one of its competitor. If products are differentiated, it is also unlikely that, on average, state aids will lead to inefficiencies: being differentiated, the aid will not have a tremendous impact on competitors but will benefit consumers.

How to Design State Aid Control(s) to Enhance Welfare?

To enhance welfare, it is first required to identify when a state aid is likely to be beneficial. These rationales could then be used in court to obtain their compatibility with EU law. Moreover, since a state aid control is costly, a special attention is required at its design. In here we will simply focus on state control at a supranational level. At a national level, the competitive neutrality principle could lead to substantial reduction of wasteful public spending. This principle could also be used at a supranational level, but it would then appear that the reason for the control is more paternalistic than really supranational.

Classical Justifications for Providing an “Aid”: Efficiency and Equity

Like other state intervention in the economy, state aids could enhance welfare when they are used to correct market failures. Compensation for the charges spent to fulfill public services obligations is probably the most known reason. In that case, if the money given to the firm is merely compensating the charges, it would not produce any advantage and would then be without any effect on competition or efficiency in the private sector. A state aid would also be beneficial if it is compensating for a positive externality produced by some entities (meaning that the entity will not have the possibility to capture all the benefits they are creating). This would be the case, for example, regarding research and development through knowledge spillovers and more generally through creating a company in a geographical area suffering, for example, of unemployment. Other rationale entails asymmetric information (and

especially some aids to risk capital to overcome the equity gap) or coordination failure (Neven and Verouden 2008).

EU law (article 107, (3) TFEU) also provides for the possibility to intervene for social or cultural reason. It, for example, refers to “aid to promote the economic development of areas where the standard of living is abnormally low or where there is serious underemployment” or “aid to promote culture and heritage conservation where such aid does not affect trading conditions and competition in the Union to an extent that is contrary to the common interest.” From a purely economic point of view, these reasons should find their justification in the positive externalities they are creating, and the efficient mean to achieve these ends should be considered (e.g., direct income transfers instead of aids to firms).

Designing an Efficient Framework

If economics could help to understand the logic of state aids, it reveals itself very limited at a practical level since it cannot provide clear-cut categories. It could nevertheless identify some key elements and trade-offs for aids controlled at a supranational level.

First, since enforcement is costly, it would make sense to allow for exemptions per categories or some per se condemnation of some subsidies or aids – these categories would then evolve with new theories and empirics. The WTO is doing that for aids regarding exports. EU law has developed “general block exemption regulation” (Council Regulation No 994/98 of 7 May 1998, amended by Council Regulation No 733/2013 of 22 July 2013) but no per se condemnation especially since Commission’s emphasis of the potential usefulness of state aid in improving the market outcome (European Commission, 2005, State Aid Action Plan, less and better targeted State aids). Moreover, for some exemptions (such as the one provided by 107 (3) TFEU), a balancing test is still required and the burden of the proof simply shifted. More interestingly, the standard of proof required is also playing a role. For example, in Philip Morris case (C-730/79), the ECJ showed a tendency to equate selectivity with distortion of competition. More recently, the necessity for an

empirical proof of the aid was questioned (T-479/11 and T-157/12). In any case, legal certainty is required to lower the administrative costs of state aid control (even though it will lead to a higher number of some false-positive and false-negative cases).

Second, a state aid control could be designed to work *ex ante* (through notification) or *ex post* (through litigation). The efficiency of one over the other remains unclear, and empirical data are lacking. Of course, the efficiency will depend, among other things, on the possibility to access courts, the time required for a decision to occur, and the efficiency of the *ex ante* screening.

Third, economic reasoning would recommend a differential depth of analysis depending on cases. For example, state aids in oligopolistic markets are, on average, more dangerous than in markets where products are heavily differentiated; requiring the same administrative burden to settle these situations is expected to be inefficient.

Conclusion

The economic analysis of state aids is a relatively new field with very few papers before 2000. Regarding the amount of researches in competition policy, this situation could be surprising. The fact that such a system does not exist in the USA could provide some information. Nevertheless, the fact that it is difficult to identify a simple set of core questions or core mechanisms, and the inherent complexity of state aid mechanisms requiring the use of a vast array of fields in economic theories, is probably delivering stronger explanation for the relative scarcity of researches. Considering its political importance in the EU context, this situation is bound to evolve.

State-Owned Enterprises

Michael Trebilcock

University of Toronto, Toronto, ON, Canada

Abstract

This entry reviews the performance of state-owned enterprises (SOEs) in both developed and developing countries, comparing performance with private sector counterparts in the same or other jurisdictions and their own performance before and after privatization. It then reviews alternative privatization modalities, including voucher privatizations, management buyouts (MBOs), privatization through the sale of state property by direct sale or public offerings, and partial privatization. It then reviews alternative reform strategies, including management contracts, performance contracts, policies to increase competition in sectors dominated by state-owned enterprises, and public-private partnerships (PPPs).

Trends in the Role of State-Owned Enterprises in Developed and Developing Country Economies

State-owned enterprises are sometimes referred to as “structural heretics” (Hodgetts 1971). On the one hand, they typically engage in commercial activities often associated with private enterprises. On the other hand, while owned by the government, they typically have some degree

of operational autonomy from the government, although subject to the government’s ability to appoint members of the Board of Directors and often senior management and approve major capital expenditures and sometimes long-term business plans.

SOEs were a relatively minor phenomenon in developed economies until World War II. While the share of mixed economies accounted for by state-owned enterprises had been on the rise since the early 1930s, the economic scope of the SOE sector at that time was fairly limited as such firms were concentrated mainly in a narrow range of industries or sectors, especially monopolistic public utility-type industries such as port authorities, railroads, and water and electricity distribution systems (Vernon and Aharoni 1981 at 8). However, the period following World War II witnessed a widespread expansion of the SOE sector in many developed countries, for a variety of reasons. SOEs were established in order to maintain employment in declining industries, to merge weak local firms, to prevent the acquisition of local firms by foreign enterprises, and to invest in industries for which private capital was unavailable. Prior to the onset of the privatization wave of the 1980s and 1990s, reflecting “supply-side” policies adopted throughout much of the world in the Thatcher-Reagan (Washington Consensus) era, the contribution of the SOE sector to GNP across the industrialized world was often in excess of 10 %: the share of GNP accounted for by SOEs was 22 % in Italy, 25 % in Austria, and more than 11 % in the UK. SOEs in developed countries dominated a number of strategic sectors of the economy, including energy, public transportation, communications, and in some countries forestry, iron, steel, and financial institutions (Aharoni 1986 at 1–2).

Similarly, the state sector in developing countries played an equally significant and in many cases a larger role in the economic life of these nations prior to the privatization movement of the 1980s and 1990s. Data from the 1970s reveals that the GDP share of nonfinancial SOEs fell within the 7–15 % range for most developing countries, although some countries in North Africa and Eastern Europe had state shares of GDP that approached 65 %. In several sub-Saharan African

countries, the share of wage employment attributable to SOEs ranged between 40 % and 74 %. Finally, in some developing countries, the industrial sector was almost synonymous with state-owned enterprise (*ibid.* at 17–25).

Despite extensive privatization of SOEs in both developed and developing countries in the 1980s and 1990s, they still play a significant role in many economies. A 2011 OECD working paper (Christiansen 2011) based on questionnaire responses from 27 of the 34 member countries covering the years 2008 and 2009 finds that while state ownership of enterprises has declined in recent decades, employment in state-owned organizations across the OECD still exceeds six million individuals, and the value of all SOEs combined is close to US \$2 trillion. In addition to the direct government ownership of these enterprises, in many countries the state holds minority stakes in listed enterprises that are significant enough to confer effective control on it. These enterprises, of which 54 were listed at the end of 2009, employ an additional three million people and are valued at close to US \$1 trillion. State-owned enterprises are increasingly concentrated in a few strategic sectors. Around half in value terms of all state-owned enterprises in OECD countries are located in the utilities sectors, such as transportation, power generation, and other forms of energy production and distribution, and a further quarter are accounted for by financial institutions (For the Canadian experience, see Iacobucci and Trebilcock (2012)). Among developed countries, the Thatcher Government in the UK in the 1980s initiated the most thoroughgoing privatization program, privatizing cable and wireless providers, coal, steel, gas, electricity, water, and airline and airport industries, automakers, railways, and shipbuilding (as well as public housing).

As a consequence of the privatization wave of the 1980s and 1990s, promoted by the World Bank, IMF, and other development agencies as an element of “the Washington Consensus,” developing countries have also witnessed a sharp reduction in most cases in the extent of the states’ involvement in these countries’ economies. For instance, as of 2003, 22 former communist

countries located in Europe and Central Asia possessed a private sector share of GDP that exceeded 50 % – up from only 9 % in 1994. Similarly, in China, the state share of GDP has dropped to less than 20 %, after accounting for almost 80 % in 1978 (Sunita Kikeri and Aishetu Kolo, “State Enterprises: What Remains?” World Bank. Public Policy for the Private Sector, note no. 304). However, data gathered by the World Bank suggests that on average, SOEs still account for between 20 % and 40 % of output in a number of many developing countries (Shapiro and Globerman 2012). In most sub-Saharan African countries, for example, state-owned enterprises still operate in many sectors of the economy and in aggregate account for more than 15 % of GDP, which is only a slight decrease since 1991. Similarly, state-owned enterprises continue to constitute a significant economic presence in many of the countries in the Middle East and North Africa, accounting for more than 50 % of GDP. In India, the state-owned sector produces 95 % of India’s coal, 66 % of its refined oil, 83 % of its natural gas, and approximately one-third of its finished steel and aluminum. In China, state-owned enterprises still employ almost half of the country’s 750 million workers, control 57 % of its industrial assets, and control a number of key industries, including electricity generation and distribution, financial services, and telecommunications (Kikeri and Kolo, *supra* note 7 at 2.).

Rationales for State-Owned Enterprises

While there is immense heterogeneity of experience in the developed world with respect to the creation of SOEs or the nationalization of previously private activities, Toninelli contends that the motives for such activity can be grouped into three broad categories (Toninelli 2000 at 5–9). First, there are political or ideological reasons for nationalization. In particular, historically, ideological motivations not only were fundamental to the nationalization policies of fascist and communist countries but were influential in the expansion of state involvement in countries such as France, Austria, the Netherlands, and the UK following

World War II. Nationalization programs instituted during this period were based on the belief that enlarging the public sphere could facilitate a fundamental redistribution of power within society, engendering a new equilibrium in which the power of labor was enhanced, and corporations would be responsible to the whole community for their decisions. Second, there were social motives for nationalization. These included the desire to guarantee full employment, to offer better working conditions to the labor force, and to pursue nation-building or reconstruction objectives. Finally, there were a number of economic reasons underlying the initiation of state activity, including addressing market failure in cases of natural monopoly, rescuing sectors of the economy in financial distress, and promoting economic growth in underdeveloped regions or sectors.

SOEs emerged in the developing world after World War II for a rather similar mix of political, ideological, and economic reasons. They were often formed (and subsequently expanded) to marshal support for new and fragile governments in developing countries. Developing country governments were also often influenced by the spread of socialist ideology following World War II, which dictated that the state should control the commanding heights of its economy (see, e.g., Haririan 1989 at 10; Muir and Saba 1995 at 11; Gillis 1980 at 263). Nationalism, often in the form of sovereignty concerns following decolonization from the mid-1950s onward, similarly fueled the desire for developing countries' governments to control the strategic sectors of their economies. SOEs were also advocated as a workable method of income redistribution – for example, by reducing prices of goods primarily consumed by the poor – especially in developing countries with large informal sectors in which income redistribution could not practically be accomplished through a tax-and-transfer system. The primary economic motivation behind SOEs was increased capital investment designed to address low domestic savings rates in many developing countries, which also often lacked the institutions, especially effective financial intermediaries, necessary to facilitate efficient capital allocations. Moreover, it was widely believed that developing

countries suffered from particular forms of market failures, such as low-level investment traps and a lack of basic infrastructure (see Smith and Trebilcock 2001 at 218, 219).

Evaluating the Performance of SOEs

A number of factors complicate the evaluation of the performance of SOEs. First, it is often difficult to determine or specify the objectives according to which performance should be measured. SOEs are often expected to achieve multiple and even conflicting economic, social, and political goals. The success of a firm could be assessed according to its internal efficiency or its contribution to social welfare, economic growth, or employment creation, to name a few examples. Economic theory would suggest that SOEs in general are likely to be less efficient, on conventional economic performance criteria, than private enterprises due to (1) the ownership effect and (2) the competition effect.

In the modern large corporation, there is a division between principals (the owners or shareholders) of the organization and the agents (the management and employees). The governance structure of the corporation such as the election of directors by shareholders (voice) or the ability to sell shares (exit) if disaffected with performance is designed to ensure that the principals (shareholders) have effective control over their agents' actions, and the interests of the agents are aligned with those of the principals so that agency costs are minimized. In addition, the market creates further managerial incentives to improve the organization's performance, as it rewards proven management skills and punishes inadequate performance through product market responses, markets for corporate control, markets for managerial talent, and bankruptcy laws (see Vickers and Yarrow 1998). In the context of SOEs, however, often both the governance structure of SOEs and the market have a much more attenuated impact on managerial performance. This is because SOE managerial appointments are often made on the basis of politics rather than merit and because SOEs are not subject to

traditional market risks such as takeovers or bankruptcy. In the private sector, shareholders often monitor the activities of a corporation, because they expect returns from their investments in monitoring. In the case of SOEs, the owner is the state, and thus, in some sense, each citizen can be considered a shareholder and will realize few personal gains from investing in monitoring efforts and cannot exit if disaffected with performance, while citizens as a whole face major collective action problems in coordinating their monitoring efforts. Further, because SOEs often face multiple economic and noneconomic objectives, it is difficult for SOE monitors to properly assess the performance of managers, who can blame poor enterprise financial performance on noncommercial objectives.

Another possible explanation for the inefficiencies of SOEs is the fact that, in the absence of natural monopoly, private enterprise encourages competition, whereas government ownership tends to encourage monopoly. Competition engenders allocative efficiency by removing the ability to set prices from the monopolist and placing it in the market. In theory, competition also engenders productive efficiency by encouraging producers to minimize costs. Where cost reductions permit producers to earn economic profits, new producers will enter the market, once again driving prices down to the marginal cost of supply. In these circumstances, constant attention to productive efficiency becomes a matter of an organization's very survival. In contrast, state-protected monopolists are not faced with the threat of being priced out of the market place and so do not have the same incentives to increase productive efficiency. However, the empirical evidence for both developed and developing countries does not conclusively support these theoretical predictions.

Mary Shirley and Patrick Walsh provide an extensive review of a number of these empirical studies (Shirley and Walsh 2000). Indeed, the 52 studies that are reviewed span the period from 1971 to 2001, use a variety of performance measures, and are balanced with respect to developing/industrialized nations. Additionally, a variety of competitive environments are

considered, from statutory monopoly to perfect competition. Of the 52 papers, 32 conclude that the performance of private firms is significantly superior to that of public firms, 15 find either that there is no significant relationship between ownership and performance or that the relationship is ambiguous, and five studies conclude that publicly owned firms perform better than private firms. When these studies are broken down by market environment, however, several important implications emerge in regard to the impact of ownership on enterprise performance. In particular, in both industrialized and developed nations, private enterprise superiority is evident in fully competitive markets. In fact, no study found that public ownership is superior to private ownership in such a case. However, this advantage is far less pronounced in monopolistic markets, where six studies find private superiority, five find neutral results, and five find public superiority (*ibid* at 51–52). These empirical findings are thus consistent with the conclusion drawn by Vickers and Yarrow that where firms face little product market competition and are extensively regulated, there is no generally decisive evidence in favor of either public or private ownership (Vickers and Yarrow 1991). Smith and Trebilcock provide an explanation for this finding, suggesting that, in highly regulated environments, the incentive and monitoring effects normally associated with private ownership are muted. More specifically, they suggest that excessive regulation inhibits the monitoring capacity of shareholders by allowing managers to hide poor management performance behind claims of distortionary government regulation (Andrew Smith and Michael J. Trebilcock 2001 at 225). Thus, while private enterprise is generally to be preferred on internal efficiency grounds, the empirical evidence suggests that ownership and competition both have a significant impact on firm efficiency and underscores that few gains can be expected from the privatization of state-owned enterprises into uncompetitive markets.

Another strand of empirical work compares the pre- and post-privatization performance of SOEs and finds that in most cases privatization has a positive effect on economic performance: divested firms mostly become more efficient,

more profitable, financially more robust, and increase their capital investment spending. While these results hold for transition and non-transition economies, the results are far more robust for upper- or middle-income countries than for low-income developing or transition economies (Megginson and Netter 2001 at 381). Indeed, much of the research focused on developing or transition economies finds that privatization generally increases social welfare when implemented in an appropriate institutional and regulatory environment, suggesting that unless privatization is coordinated with significant private sector reform, the lack of competition in low-income economies may result in minimal gains to society (Adam et al. 1992 at 71). David Parker and Colin Kirkpatrick argue that for privatization to have a significant impact on performance over the longer term, institutional capacity needs to be assessed prior to privatization to ensure that the scale, coverage, and sequencing of privatization are consistent with the available capital and management resources and that administrative capacities are in place to enable a privatization process that is fair, transparent, and efficient (Parker and Kirkpatrick (2005) at 535). Similarly, in their review of 34 empirical studies evaluating the effect of privatization on both macro- and micro-economic indicators in former communist countries, Saul Estrin et al. find that while privatization to foreign owners generally results in the rapid improvement of the performance of firms, the effects of privatizing to domestic owners are far less impressive and vary fairly significantly across countries (Estrin et al. 2009 at 29). Estrin et al. speculate that the performance differential between foreign and domestic owners is attributable to the fact that foreign firms often bring in strong expatriate managers, invest heavily in domestic training, and introduce more advanced systems of corporate governance, thus enabling them to compensate to a considerable extent for the underdeveloped legal and institutional system in many transition economies.

Finally, the importance of effective competition policies and appropriate regulation is of critical importance in the context of the welfare effects of privatizations in the infrastructure

sector. In theory, the gains in firm profitability and operational performance from selling an inefficient public sector monopoly to an unregulated private owner can easily be outweighed by the welfare losses imposed on consumers and the economy as a whole from suboptimal access to important products or services. While the existing empirical evidence has thus far concluded that divestiture substantially improves economic welfare on the whole by increasing investment and improving productivity, most privatizations have produced gains for some and losses for others. The distribution of these welfare effects therefore depends crucially on the fairness and the capacity of the regulatory system and effective competition and competition policies (Kikeri and Nellis 2004 at 97–100). Thus, in summary, the empirical evidence is consistent with the notion that that privatization can improve economic performance, but performance improvement relies also on other structural reforms.

Privatization

Assuming that privatization is desirable and that various economic and political prerequisites are to a greater or lesser extent in place, there are numerous methods of privatization that are available as models for implementation. In 1996, Josef C. Brada categorized various methods (Brada 1996 at 68), and, while not an exhaustive list, it provides a useful framework within which to understand the different ways in which privatization can be undertaken. Drawing on Brada's taxonomy, this section will survey four different types of privatization, assessing both the costs and benefits of each.

Vouchers

A form of privatization that has been used primarily in Central and Eastern Europe is mass or voucher privatization. This involves the distribution of vouchers for free, or at a nominal cost, that enables eligible citizens to bid for shares of SOEs that are being privatized (or financial intermediaries such as mutual funds). Although these schemes have resulted in fundamental changes to the ownership of business assets, often they have

not changed the effective control over these assets because of the wide diffusion of share ownership, thus leaving incumbent managers or small concentrated groups of shareholders in control of the assets with little accountability to the new owners (Megginson and Jeffrey Netter, 2001 at 324). Sweeping privatization (often through vouchers) of SOEs in the former Soviet Union in the early 1990s (“shock therapy”) without supporting legal and regulatory institutions was widely perceived to have led to a form of crony capitalism where political insiders (“oligarchs”) captured state assets at undervalue and sometimes looted them, contributing to a precipitous decline in GDP per capita.

Management Buyouts (MBOs)

Employee buyouts involve the transfer of the rights of ownership of industrial or commercial facilities to those who are employed in them. However, in the case of MBOs, the existing management is the buyer (Sondhof and Stahl 1992 at 210). MBOs have been advocated in situations involving small- and medium-sized enterprises (such as those formed by the dissolution of former combines or large enterprises) and as a way to draw upon a substantial pool of “privatization demand” from the people who work in the enterprise (Sondhof and Stahl, *ibid*; Bennett 1997).

However, given the importance of new human capital to the success of a divested SOE documented in many studies, MBOs are often a poor method of privatization (since enterprise management typically does not change as a result of an MBO). There are a number of other reasons why MBOs are often not an optimal method of divestiture:

- MBOs are often highly leveraged, leaving the new enterprise vulnerable to macroeconomic shocks.
- Managers of SOEs, given their information advantages and political influence, may be able to purchase their SOEs for less than the fair market value.
- Management may not be able to secure adequate financing, leaving the developing country government (acting as a *de facto* guarantor or lender) bearing the risk of enterprise failure.

Thus, notwithstanding that MBOs often have the support of the workforce, the MBO is not generally an efficient method of divestiture.

Privatization Through the Sale of State Property

The sale of state property is the method by which a government “trades its ownership claim for an explicit cash payment” (Megginson and Netter, 2001). As discussed by Megginson and Netter, this category can be subdivided into two different approaches. The first is *direct sale* whereby an SOE, or one of its component parts, is sold to an individual, a corporation, or a group of investors (typically the highest bidder). The second option is *share issue privatization* (also known as an SIP), where some or all of the government’s holding in an SOE is sold through a public share offering. The sale of state property serves several concrete objectives, including producing revenue for the state, restructuring organizations, and attracting foreign investors (Brada 1996).

This method of privatization can be controversial, however, as foreign investment represents a paradox to developing governments: while capital-starved developing countries are in need of foreign capital, foreign investment has often been perceived as a neocolonialist threat to newly emergent states attempting to fashion their own societies rather than be absorbed into the political economy of the developed world. Thus, domestic investment may be more attractive to many developing economies, implying that a country’s savings rate (savings as a percentage of GDP) will be a significant factor in the determination of the mode of divestiture adopted. This suggests that a developing country with a higher savings rate is likely not only to rely to a greater degree on domestic investment but also to employ the public offering more frequently as a means of placing some portion of large SOEs in domestic rather than foreign hands. Moreover, developing countries with higher savings rates are more likely to have the financial institutions necessary to facilitate a public offering. To date, direct sales to the domestic private sector in developing countries have been concentrated in smaller-scale activities associated with the commercial,

manufacturing, service, and agricultural sectors. The divestiture of large enterprises, such as utilities, has relied more on foreign direct investment and public share issues. There has also been a tendency for developing countries to privatize in a macroeconomic crisis when there is an urgent need for additional government revenues to finance budgeting deficits. However, the precipitous sale of SOEs may result in fire-sale prices or alternatively a proclivity to turn state-owned monopolies into private monopolies in order to enhance the sale price.

Partial Privatization

Partial privatization of an SOE may be a desirable interim option for governments for whom full privatization is not politically desirable or feasible. Partial privatization may take the form of a partial public offering that, if the stock is widely traded, will introduce stock prices (and changes thereto) as a benchmark of an SOE's performance, as well as creating a private constituency with a direct stake in SOE efficiency. Alternatively, government could sell a minority interest to a single commercial partner or joint venture partner with needed capital and expertise and a role in the SOE's governance, again with a direct stake in enhanced SOE performance. Under both options, full privatization may ultimately be rendered more politically feasible. Government credibility may, however, prove a serious problem with both of these options, in that the stakes of the minority investors are at risk of expropriation or devaluation by changes in policies by the controlling shareholder or government, being motivated by considerations other than efficiency. Hence, minority shareholders may be difficult to attract at all or only at severely discounted acquisition prices, reflecting political risk.

Alternative Reform Strategies

While there are many options in terms of how to privatize SOEs, there are also reform alternatives to privatization that should be identified. The following reforms, to a greater or lesser extent, seek to benefit from the ownership and/or competition effect.

Management Contracts

A management contract is an agreement between a government and a private party (often enforceable through international arbitration or governed by the law of a recognized center of commerce) by which the private party agrees to operate the assets of an existing SOE for a fee, which will often be tied to performance. In other words, management contracts privatize SOE management without divesting the SOE's assets.

While there is evidence providing some support for the use of management contracts as a means to improve SOE efficiency Shirley et al. (1995) at 136–139. Shirley studied the experience of 20 contracts in several countries and industries, measuring their impact on SOE performance in terms of increases in post-contract profitability and productivity, and found that 13 out of the 20 SOEs, or 65 %, were successes. Moreover, profitability or productivity improved in three other organizations. However, they have their drawbacks. First, in order for management contracts to yield significant benefits from the incentive of private management, remuneration under the contract must be tied to organizational performance. In practice, contracts often include fixed fees, and some do not even attempt to relate fees to performance. Secondly, the limited term of a management contract may create perverse management incentives. Because of uncertainties over whether contracts will be renewed – a problem compounded by the lack of credibility of many developing country governments – management may be tempted to maximize short-term gains (e.g., by degrading assets), often at the cost of long-term performance (see Daniels and Trebilcock (1996) at 404). And while a well-drafted management contract may mitigate such perverse incentives by including longer contract terms, technological uncertainties and uncertainties relating to market demand and surrounding government policies may negatively affect the risks associated with a project over the long term, making longer contract terms relatively unattractive to private organizations (see Daniels and Trebilcock, *ibid.*, at 405; although the management contracts of the most successful organizations in the Shirley study generally have longer terms.).

An important question concerns the relative efficiency of the management contract and divestiture. As stated earlier, privatization – assuming appropriate postdivestiture competition and regulatory policies – takes full advantage of both the ownership effect and the competition effect of private ownership. Management contracts, on the other hand, do not take advantage of the ownership (or often the competition) effect and hence may be less effective than divestiture. This is because of a number of factors:

- Private ownership is more likely to result in increased capital investment than management contracts.
- Provided that the privatized SOE does not have monopoly power, divestiture may not result in the same level of transaction costs as management contracts (e.g., the costs of ongoing negotiations and monitoring) (Shirley et al. 1995 at 149).

Thus, where the economic and political prerequisites for privatization are present, privatization is likely to be a better reform alternative than management contracts. However, the key benefit of management contracts is that they can be successfully implemented in circumstances where privatization is not feasible.

Performance Contracts

A key distinction between private and public enterprises is that private enterprises are generally motivated by one clear objective – profit maximization – whereas SOEs typically face multiple, sometimes conflicting, objectives. Poorly defined and shifting corporate objectives severely inhibit the evaluation of management performance SOEs, while a lack of autonomy from government decision-makers and a failure to tie management compensation to organizational performance deter good management performance. These are problems that *may* be resolved by a performance contract.

The three major components of a performance contract system are:

- A performance evaluation system, in which national goals are translated into explicit SOE objectives and quantified in performance criteria
- A performance information system which monitors actual achievements
- An incentive system, in which the welfare of the managers and workers of the SOE is linked to its objectives by a pecuniary or non-pecuniary reward system based on the achievement of particular target values (Hartman and Nawab 1985 at 28–30)

By the mid-1990s, performance contract systems had been implemented in 28 developing countries – mostly in Asia and Africa – but, unfortunately, despite some successes, there have also been many failures. Obstacles to successful implementation of performance contracts include ensuring that SOE managers, who enjoy a significant information advantage over their government monitors, do not use this advantage to negotiate easily attainable performance targets and ensuring that management remuneration is effectively tied to SOE performance. In one study (Dyer Cissé 1994, Background Paper, Policy Research Department, World Bank), only five of the twelve sample companies offered pecuniary bonuses as a performance award. This study also found a tendency for the governments of developing countries to breach their performance contract commitments with impunity, thereby seriously derogating from the significance attached to them by SOE managers.

Thus, the implementation of performance contracts does not appear to be a broad solution to the problem of SOE inefficiencies. Relative to privatization, performance contracts do not increase competition and they face serious obstacles in their attempt to induce good management. However, improvements can be made to the system, such as reducing bargaining inequality by channeling performance contracts through a centralized specialized agency or using published and frequently updated benchmarks from comparable entities in other sectors or countries to lower transaction costs. If these changes and assurances can be made to the performance contract systems

in LDCs, SOEs that cannot (or should not) be privatized for economic or political reasons may still benefit from improved enterprise management.

Increased Competition

While management contracts and performance contracts attempt to improve SOE performance largely through improvements in management incentives and monitoring, these types of SOE reform have little impact on the level of competition faced by an SOE. There are four means by which governments of LDCs may introduce greater levels of competition in their SOE sectors: (i) the unbundling of monopolies and exposing some elements of them to competition, (ii) the reduction of import barriers, (iii) performance-based price regulation using competitive benchmarks from other jurisdictions, and (iv) competition laws.

As in the case of the other alternative reform options, they are still a less effective option than privatization, which takes advantage of the ownership effect as well as the competition effect. However, such a strategy may be a preferable interim measure in situations where, for political or economic reasons, privatization is not a viable option. Like privatization, however, these strategies depend on the existence of strong institutions, including effective competition and regulatory authorities. The challenges in building these institutions in developing countries, however, are not negligible.

Public-Private Partnerships (PPPs)

“PPPs” is a term that exhibits a high degree of ambiguity in common usage, but it is often used to refer to projects in which the private sector designs and builds new or refurbishes and expands existing infrastructure, provides project financing, manages the asset, and operates the service. In other words, the arrangement typically involves “bundling” – or vertical integration – in the form of a consortium that brings together project designers, managers, construction companies, engineers, and financiers (Daniels and Trebilcock 1996 at 390). PPPs recover their costs through user fees, government payments,

or both. Whether the asset reverts to the public sector at the end of the contract depends upon the terms of the contract. Most PPPs implemented to date provide that ownership in the asset is retained by, or will revert to, the public sector. Over the past two decades, PPPs have been extensively employed in both developed and developing countries, mainly with respect to the construction or expansion of infrastructure facilities. In the case of many developing countries, infrastructure deficits are often massive, especially in electricity, transportation, and water supply, and governments lack the fiscal capacity to make the needed investments. PPPs provide an intermediate strategy between SOEs or their privatization (see Trebilcock and Rosenstock 2015).

PPPs are promoted on several grounds. The bundling aspect of PPPs incentivizes the builder-operator to incorporate long-term operating cost considerations in the design and construction phases of the project and arguably also reduces the coordination costs that would otherwise be faced by various departments or agencies of government in undertaking all of the functions performed by a vertically integrated consortium (Delmon 2009 at 10). Similarly, as the PPP transfers to the builder-operator the financial risks associated with design, construction, and operation, there is a heightened incentive to mitigate cost and time overruns. PPPs have also been viewed by some governments as a means of shifting spending off balance sheet or circumventing legislative budgetary limits. Clearly, this is problematic, as masking government liabilities does not reduce them nor is it transparent (Organisation for Economic Co-operation and Development 2008 at 21).

PPP contracts pose special problems of contractual design, monitoring, and enforcement. Typically, they involve large investments in durable, transaction-specific assets of the kind that Nobel Laureate Oliver Williamson describes as raising a bilaterally dependent contractual relationship between the parties (Williamson 1988 at 71). That is, while governments may have some choice among competing consortia *ex ante*, once they “lock into” a long-term relationship with a single consortium, there are significant risks of

mutual opportunism or “holdups” over the course of the subsequent contractual relationship.

Over the past two decades, the majority of PPP projects in developing countries have taken place in countries with relatively high incomes. Just under 60 % of total projects were undertaken in upper middle-income countries and 37 % in lower middle-income countries. Only 4 % of projects took place in low-income developing countries, although this latter number may underestimate the true extent that PPPs are used in low-income countries, especially in sub-Saharan Africa, given the increasing number of “resources for infrastructure” exchanges between Chinese SOEs and sub-Saharan African countries (although because the Chinese firms are often SOEs, these are not strictly public-private partnerships). A recent statistical analysis by the IMF found that after adjusting for population, PPP concentration was more likely in larger markets with a stronger rule of law, political stability, administrative capacity, greater consumer demand, and macroeconomic stability (Hammami et al. 2006).

A number of studies have attempted to evaluate the relative operating efficiencies of PPPs. A number of these studies have found that service quality and reliability have often improved and that labor productivity has greatly increased through substantial reductions in public sector employment (Andrés et al. 2008; Marin 2009 at 29). The effect of PPPs on user fees yields more mixed results (Marin, *ibid.*, at 110; Andrés et al., *ibid.*; Kirkpatrick et al. 2006). As predicted by Williamson, renegotiation rates of PPPs even early in their contractual terms are quite large. Another striking finding is the limited impact of PPPs on improving access to infrastructure relative to a continuation of the *status quo*. Often very poor consumers see relatively few benefits from a PPP and continue to rely on the relatively expensive informal sector for, e.g., access to potable water (Marin 2009 at 64–65; Estache 2005 at 1). In terms of expanding access to essential infrastructure, such as water distribution or electricity, developing country governments need to build stronger incentive mechanisms in PPP contracts to provide such access or alternatively to subsidize low-income consumers directly.

Static Market Power

Rafael Emmanuel Macatangay
Centre for Energy, Petroleum and Mineral Law
and Policy School of Social Sciences, University
of Dundee, Dundee, Scotland, UK

Abstract

Static market power refers to the ability of economic agents profitably to move prices away

from competitive levels during one time period. Market power, a form of market failure, prevents the achievement of an efficient allocation of resources. The simplest example of market power is monopoly, a market in which there is only one firm. Another example of market power is oligopoly, a market in which there is a small number of firms. The determination of whether or not prices profitably deviate from competitive levels is at the heart of antitrust law and economics. Methods for analysing the unilateral change in incentives arising from merging two firms have become influential as a screening device for identifying potentially anti-competitive mergers in the EU, US, and UK.

Definition

Static market power refers to the ability of economic agents profitably to move prices away from competitive levels during one time period (i.e., a one-shot simultaneous moves game).

In a competitive economy, consumers or producers assumed to be price takers behave as if the demand or supply functions they face are infinitely elastic at prevailing market prices (Mas-Colell et al. 1995). However, if there are only few agents on either side of a market, they are likely to have market power, the ability profitably to move prices away from the marginal cost (i.e., the competitive or socially optimal level). As a form of market failure, market power prevents the achievement of an efficient allocation of resources. Static market power involves agents acting in only one period (i.e., one-shot simultaneous moves). Agents possessing market power are typically sellers. The ability of a firm to exercise market power depends on whether or not consumers can find substitutes and, therefore, varies inversely with the demand elasticity (Church and Ware 2000). The potential for supply substitution depends on the extent to which consumers can switch to alternative suppliers of the same product (i.e., homogeneous goods). If consumers cannot find substitute suppliers capable of providing the same product, then the firm will have market power. The potential for demand

substitution depends on the extent to which consumers can switch to alternative suppliers of products that are acceptable substitutes (i.e., differentiated goods).

If products are sufficiently differentiated, then they are not close substitutes and consumers will not reduce their consumption when price rises above the marginal cost. The possibilities for supply or demand substitution increase the elasticity of demand.

The simplest example of market power is monopoly, a market in which there is only one firm (Mas-Colell et al. 1995). If the monopolist faces a market demand that is continuously decreasing in price, then the monopolist will find it profitable to raise price above the marginal cost. The monopolist recognizes that a reduction in the quantity it sells allows it to increase the price on all its sales and consequently to increase its profits. The monopolist's profit-maximizing output is thus below the socially optimal level. Another example of market power is oligopoly, a market in which there is a small number of firms. If the efficient scale of operation for a firm is large relative to the size of market demand, the equilibrium number of firms could be small. Competition in an oligopoly involves strategic interaction requiring the analytical tool of game theory. In a static model of oligopoly, there is only one period of strategic interaction and firms act simultaneously. A widely used oligopoly model is the Cournot model (named after French mathematician Augustin Cournot writing in 1838) in which quantity is the strategic variable (another oligopoly model, the Bertrand model, in which the strategic variable is price, yields the social optimum even with just two firms, but is not discussed here). In a Cournot duopoly, each firm forecasts the other's output choice and chooses a profit-maximizing output for itself. Price then adjusts to clear the market. In equilibrium each firm is maximizing its profits and confirms its beliefs about the other. Using the terminology of game theory, their strategies constitute a Nash equilibrium (named after American mathematician John Nash writing in 1951) if one's choice is optimal given the other's choice and the other's choice is optimal given one's choice (Varian 2010). Neither

firm will find it profitable to change its output choice once it discovers the output choice actually made by the other.

The Cournot price and profit are lower, respectively, than the monopoly price and profit, and the Cournot output is higher than the monopoly output (Mas-Colell et al. 1995). In a Cournot equilibrium, as each firm estimates the profitability of selling an additional unit of output, it does not consider the reduction in the other's profit due to the decline in the price. If for some reason the firms in aggregate produced the competitive quantity and consequently earned zero profits, either one could benefit from a slight reduction in its output. Moreover, the slope of the marginal cost function is a key determinant of the market outcome (Vives 1999). Flat marginal costs are conducive to socially optimal behavior, but steep marginal costs, indicative of inflexible technologies, are conducive to Cournot behavior. A Cournot model can be configured to nest the two extreme outcomes of social optimality on one end and monopoly on the other (Mas-Colell et al. 1995). If the number of firms is very large, price, aggregate output, and profits approach the socially optimal levels, but if the number of firms is very small (or set to one), they approach the monopoly levels. Each firm's influence on price is negligible if there are many firms.

One criticism of the Cournot model is that, in some situations, firms seem to choose prices rather than quantities (Mas-Colell et al. 1995). One way of addressing this is to interpret quantity choices in the Cournot model as long-run choices of capacity, and thus to let price determination through the inverse demand function serve as a proxy for short-run price competition, given the capacity choices. Another criticism of the Cournot model is that, in some situations, firms seem to choose both price and quantity (Vives 1999). One way of addressing this is to deploy an analytical approach in which firms compete in supply functions. Under a supply function equilibrium ("SFE"), the strategy for a firm is a price-quantity pair that is optimal given the price-quantity pairs of other firms. The market outcome is a Nash equilibrium in supply functions. One criticism of SFE is that there are infinitely many supply

functions that satisfy the optimal market price and quantity. One way of addressing this is to introduce demand uncertainty that limits the multiplicity of supply function equilibria.

The choice of oligopoly model is ultimately a function of the features of the market (Vives 1999). For example, in the world market for crude oil, the Organization of Petroleum Exporting Countries (“OPEC”) is a major player and its aims are effectively those of a cartel (Carvajal et al. 2013). In principle firms that are not colluding ought to be playing the static Nash equilibrium at each time period. A test of Cournot rationalizability determines if the market outcome could be explained as a static Nash equilibrium. If it could not, then antitrust authorities could consider alternative explanations, such as complex or possibly collusive (i.e., dynamic) forms of strategic behavior. An analysis of data on OPEC and non-OPEC countries suggests that the behavior of oil-producing countries is not Cournot rationalizable (i.e., the Cournot hypothesis is rejected).

Whether the price or quantity competition model is better for oligopolies remains an open question (Vives 2011). SFE, which appears to be a viable alternative, has been used to model bidding for government procurement contracts, management consulting, or airline pricing reservation systems. The analysis of competition in wholesale electricity markets in different countries has been a fertile area for testing alternative oligopoly models. One of the major lessons from the international experience of electricity industry liberalization over the last two decades is that the wholesale market for electricity is prone to the exercise of unilateral market power (Wolak 2014). The elasticity of electricity demand tends to be inelastic, close to zero in the short run, and well below one within a year (Stoft 2002). Market power in wholesale electricity markets is exercised strategically by reducing output that could be produced profitably at the market price (i.e., quantity withholding) or raising the price of output above the marginal cost (i.e., financial withholding). Either would steepen the supply curve and the outcomes deviate from the socially optimal levels for price, quantity, and profit. For the analysis of competition in wholesale

electricity markets, Cournot models have been used in California, the Pennsylvania-New Jersey-Maryland area, and New England and SFE models, in England and Wales and Texas (Willems et al. 2009). An analysis of competition in the German electricity market using both Cournot and SFE models shows that each model explains similar proportions of observed price variations.

The determination of whether or not prices profitably deviate from competitive levels is at the heart of antitrust law and economics. The upward pricing pressure (“UPP”) methodology and the gross upward pricing pressure index (“GUPPI”) have become influential as a screening device for identifying potentially anticompetitive mergers in the EU, USA, and UK (Davis and Fletcher 2013). The underlying rationale is to focus on the key likely anticompetitive effect of a merger, the unilateral change in incentives arising from merging two firms. One interesting implication is that high profits are not necessarily indicative of market power. High profits can occur in a situation of effective competition (e.g., through superior management), or a low profit margin could occur in monopoly (Bork and Sidak 2013). Using a firm’s profit data to infer market power might lead a court or competition authority to the wrong conclusion.

The current Merger Regulation of the European Commission (the “Commission”) ensures that competition and consumers are not harmed by excessive concentrations of market power (European Commission 2014). One of the key assessments is a test for a significant impediment of effective competition (“SIEC”). Although SIECs most prominently arise from the creation or strengthening of a dominant position, the test also addresses the issue of mergers in which the merged entity is not dominant but potentially has anticompetitive “non-coordinated effects.” In an oligopoly in which no firm is individually dominant and collusion is unlikely, merging firms may have an incentive to increase their prices unilaterally even if they do not become dominant, and the remaining firms, benefitting from the reduction in competitive pressure due to the merger, might also increase their prices. The test is designed to

address mergers which allow firms unilaterally to raise prices but do not create or reinforce a single or collective dominant position. If competitive constraints are sufficiently strong, a merger resulting in a high combined market share of the merging firms may not have a negative impact on competition or consumers.

The merger control regime in the UK generally but not exclusively involves the Competition and Markets Authority (“CMA”) for UK companies covered by the provisions of the Enterprise Act 2002, as amended; the commission for mergers under the Merger Regulation; and the relevant sectoral regulators for natural gas and electricity markets, water services, rail services, civil aviation, health, and (from 1 April 2015) financial services (Competition and Markets Authority 2014). The CMA has a duty to refer, for an in-depth “phase 2” investigation, any relevant merger situation that risks resulting in a substantial lessening of competition (“SLC”) in a UK market. UK competition authorities have been using techniques very closely related to UPP or GUPPI to diagnose unilateral price effects (Shapiro 2010). The restoration of the dynamic process of firm rivalry through remedies that reestablish the market structure expected in the absence of the merger (i.e., structural remedies, such as divestitures) is projected to address the root cause of adverse effects (Competition Commission 2008). Structural remedies are generally preferable to behavioral remedies (e.g., price caps, supply commitments, or restrictions on long-term contracts) which not only are deemed unlikely to deal with an SLC and its adverse effects as comprehensively as structural remedies but also may result in distortions to the socially optimal outcome.

The 2010 Horizontal Merger Guidelines of the US Department of Justice and the Federal Trade Commission reflect the ascendancy of unilateral effects as the theory most often pursued by US competition authorities (Shapiro 2010). A key element of the analysis is the disincentive created by the merger to sell additional units of product 1 if they cannibalize unit sales of product 2 (the disincentive is an opportunity cost borne by the merged firm for selling product 1). A merger

generates net upward pricing pressure for product 1 if the opportunity cost exceeds the efficiencies for it. The treatment of unilateral price effects rests on economic principles related to how firms account for opportunity costs (i.e., cannibalization), when pricing and promoting product lines containing substitute products, and how higher costs tend to lead to higher prices. Moreover, there is additional flexibility in the implementation of the hypothetical monopolist test (“HMT”). Under the HMT, a market consists of a product (or group of products) and a geographic area in which it is sold, such that a hypothetical, profit-maximizing firm (that is both not subject to price regulation and the only present and future seller of the product in the area) would impose a small but significant and non-transitory increase in price (“SSNIP”) above prevailing or likely future levels. The purpose of defining the market and measuring market shares is to assist in the analysis of competitive effects. The use of market shares and concentration is in the context of the smallest relevant market satisfying the HMT.

Strict Liability Versus Negligence

Vaia Karapanou
Athens, Greece

Abstract

Strict liability and negligence are the basic rules that courts apply to affirm tort liability and award damages. Law and Economics is concerned with the efficiency of the rules and therefore compares strict liability and negligence based on the incentives they provide accident parties to minimize total accident costs. To analyze the implications of the two liability rules for economic efficiency, a distinction is made between unilateral accidents, in which only the injurer can affect the probability of accident occurrence and the magnitude of the accident losses, and bilateral accidents, in which both accident parties can affect the probability of accident occurrence and the magnitude of the losses. Provided that damages are perfectly compensatory and that the due care level is set to be equal to the optimal level of care, both rules induce optimal precaution in unilateral accident settings; however, only the rule of strict liability induces the injurer to engage in the optimal activity level. In bilateral accident settings, all rules besides the rule of simple strict liability induce both accident parties to take optimal care; however,

none of the rules can simultaneously create both accident parties incentives to engage in the optimal activity level. The litigation costs per trial are higher under a negligence rule and its variations because courts have to determine if the injurer and/or the victim complied with the set level of due care. In accident contexts where a preexisting market relationship exists between the injurer and the victim, such as in the case of a defective product, a critical factor is whether consumers (victims) are aware of the risk level of the product. If they are, all liability rules create the injurer optimal precaution incentives; if they are not, only the rule of strict liability with a defense of contributory negligence creates optimal care incentives. Today, the rule of negligence is the most commonly used rule of tort liability.

Definition

The rules of strict liability and negligence are the basic rules that courts apply to affirm tort liability and award damages. Under a rule of strict liability, a person is liable for all the accident losses she causes. Under a rule of negligence, a person is liable for the accident losses she causes only if she was negligent. Being negligent implies that the person took less care than the minimum acceptable level prescribed by the law and/or by the court. Law and Economics is concerned with the efficiency of the rules and therefore compares strict liability and negligence based on the incentives they provide to reduce accident losses.

Introduction

Tort law stipulates under which circumstances a person suffering civil harm such as loss or impairment of property, reputation, health and life is entitled to damage compensation. In his seminal book *The Costs of Accidents*, Calabresi (1970) proposes that the principal goal of tort law besides justice is to improve social welfare by minimizing the total costs of accidents. These include the costs of taking precautions to avoid accident

occurrence, the accident losses that are still expected to occur, the costs involved with spreading the losses through the insurance mechanism, and the administrative costs of the legal system relating to the adjudication of tort damages. The prospect of being held liable and having to bear accident losses provides potential wrongdoers incentives to take care and to better control their activity. Economic analysis of tort law compares liability rules to determine under which circumstances strict liability or negligence is more suitable to improve social welfare by creating incentives to take precautions that reduce accident losses.

Brown (1973) and later on Shavell (1980) developed models formalizing the ideas of Calabresi (1970) with regard to the implications of various liability rules for economic efficiency. These basic models are not concerned with the costs of spreading the losses and the administrative costs of the legal system but rather focus on reducing the costs of precaution and the expected accident losses. The models assume that accidents may occur between two parties, an injurer and a victim, causing losses L . Both parties make decisions regarding their activity, depending on the liability rule that is in place, to avoid having to bear accident losses. The decisions involve choices regarding how much care x to take and how often to engage in the activity. The probability of accident occurrence, denoted by p , is affected by these decisions as well as the magnitude of the expected accident losses denoted by pL . Figure 1 provides a graphical representation of how the costs of accidents are influenced by the choices of an accident party regarding her level of care. The cost $B(x)$ of taking a certain amount of care is depicted as well as the expected accident losses given the level of care $p(x)L$ (Landes and Posner 1987; Cooter and Ulen 2011). The upward slope of line $B(x)$ indicates that the marginal cost of precaution increases as more care is taken. The downward slope of line $p(x)L$ indicates that the marginal expected accident losses decrease as more care is taken. The goal is to choose a level of care that minimizes the sum of the costs of care and the expected accident losses, which together constitute the expected total costs of accidents

(TC). The following sections make a distinction between unilateral and bilateral accidents (Shavell 1980, 1987) to discuss the implications of strict liability and negligence for economic efficiency. The analysis is mainly based on Cooter and Ulen (2011), Landes and Posner (1987), Polinsky (2011), Posner (2010), Schäfer and Ott (2005), and Shavell (1980, 1987, 2004).

Unilateral Accidents

In a unilateral accident, it is assumed that only the injurer can influence the probability of accident occurrence and the magnitude of damages, while on the other hand, only the victim incurs accident losses. In this setting a liability rule is efficient if it provides the injurer incentives to exercise optimal precaution that minimizes total accident costs.

Under a rule of *strict liability*, the injurer bears the cost of precaution and the accident losses that are still expected to occur, namely, she has to pay for the total accident costs. The injurer will take this prospect under consideration and compare the costs of taking precautions and the benefits arising thereof in the form of a reduction in expected accident losses. Given that her private costs from the accident coincide with total accident costs, the injurer takes a level of care that is also the socially optimal level of care x^* , as it minimizes total accident costs. Besides choosing the level of precaution, the injurer will also decide on how often to engage in the activity. Given that an increase in the level of activity will result in an increase of the accident probability and/or of the magnitude of accident losses, the injurer will compare her benefits from engaging in the activity more often and the costs arising thereof in terms of an increase in expected accident losses. She will therefore also be induced to choose a socially optimal level of activity.

Under a *negligence* rule, the injurer will have to pay for the total accident costs only if she did not take the level of due care set by the law and/or by the courts. Due care, frequently also referred to as reasonable care, is usually defined as the ordinary precaution that a reasonable person would have exercised under the circumstances,

compared to the precaution that the injurer actually exercised. To decide whether the injurer is negligent, the court will have to consider if the injurer took the due level of care. The most famous and commonly used test of negligence was developed by the American judge Learned Hand (1947), who suggested that an injurer is negligent if the burden B of her precautions is less than the gravity of the loss L multiplied by the probability p that an accident occurs, that is, if $B < pL$. Assuming that judge Hand had marginal values in mind, his rule implies that an injurer can escape liability if she takes additional precautions to the extent that the marginal costs of her precautions equal the marginal benefit arising from the resulting decrease in expected accident losses. The level of care that satisfies this equality is the socially optimal level of care. Expressed in algebraic terms, the rule obtained is $B'(x^*) = -p'(x^*)L$. If the due care level is set to be equal to the socially optimal level of care x^* , then total accident costs will be minimized as the injurer will prefer to comply with the level of due care to avoid having to pay for the total accident losses. The negligence rule hence implies that the injurer will be responsible for the accident losses circumscribed by the bold line in Fig. 1. Given that the injurer will only have to take due care to escape liability, she will only consider her private benefits from engaging in the activity and will not take into account the effect of the activity on expected accident losses. She may therefore choose to engage in the activity too often.

Liability Rules Compared

A comparison of the rules of strict liability and negligence shows that both rules can provide the injurer incentives to exercise socially optimal precaution that minimizes total accident costs. However, only the rule of strict liability can create incentives for choosing a socially optimal level of activity (Shavell 1980). Furthermore, the strict liability rule is efficient only if damages awarded by courts are perfectly compensatory in order to induce the potential injurer to take optimal care and engage in optimal activity levels. If damages are systematically underestimated or overestimated, then the injurer will be respectively induced to take a suboptimal or an excessive level of precaution and activity. Under a negligence rule on the other hand, the damages need not reflect the total loss incurred but rather be high enough to make taking optimal care more attractive than taking lower care. As long as the costs of taking optimal care are lower than the total accident costs with less than optimal care, the injurer will choose to take optimal care. However, inefficient precaution may also occur under a negligence rule if the level of due care is not set to be equal to the socially optimal level of care. As the injurer will always comply with the due care level to avoid being held liable, a due care level that is set below the socially optimal level of care will motivate her to take suboptimal precaution, while a due care level that is set above the socially optimal level of care will induce her to take excessive precaution. In the latter case, if the costs of

Strict Liability Versus Negligence, Fig. 1 The influence of the injurer's care choices on the costs of accidents in a unilateral accident setting

precaution exceed total accident costs, the injurer may choose to take a lower level of care that is closer to the socially optimal level. The effect of random errors will be greater under a negligence rule than under a strict liability rule. Random errors in the assessment of damages under a strict liability rule will not change the incentives for precaution as long as damages are correct on average. On the other hand, random errors in setting the due care level under a negligence rule will lead to an increase in precaution as they will induce the injurer to take more care than the due care level to make sure that she will avoid liability (Calfee and Craswell 1984, Craswell and Calfee 1986).

Another difference between the rules of strict liability and negligence regards the administrative costs of trial. Under a rule of strict liability, the court will only need to establish causation between the accident losses and the activity of the injurer, whereas under a rule of negligence, the court will also have to determine if the injurer is negligent by examining whether her level of care fell short of the due care level. It is therefore safe to conclude that the cost per trial will be higher under the rule of negligence. Given that it is easier to prove harm under strict liability, the number of damage claims is likely to be larger than under negligence; however, as it will be easier to predict the outcome of the trial, many of the claims under strict liability will be settled out of court.

Bilateral Accidents

In bilateral accidents it is assumed that both the injurer and the victim can influence the probability of accident occurrence and the magnitude of damages. In this setting a liability rule is efficient if it provides both the injurer and the victim incentives to exercise a level of precaution that minimizes the expected total costs of the accident.

Evidently, a simple *strict liability* rule cannot motivate both accident parties to exercise optimal precaution. As explained in the previous section, under the rule of strict liability, the injurer is liable for the total accident costs and therefore will take

an optimal level of care and of activity in order to minimize them. However, given that the victim's losses will be fully compensated, the victim will not be induced to take any precaution or control her activity level. Therefore, the rule of simple strict liability will not provide efficient incentives for precaution in the case of bilateral accidents.

A variation of the rule of strict liability that deals with the problem of inadequate incentives for the victim is the rule of *strict liability with a defense of contributory negligence*. Under this rule the injurer is liable for the total accident costs unless the victim was negligent, in which case the victim has to pay for her losses. Being negligent implies that the victim took less care than the due care level set by the law and/or by courts. Under this rule the victim will choose to take due care to avoid having to pay for her accident losses. If courts set the due care level for the victim to be equal to the socially optimal level of care y^* , then total accident costs will be minimized as victims will be induced to exercise optimal precaution to escape liability. The bold line in Fig. 2 shows the costs that the victim will have to bear under a rule of strict liability with a defense of contributory negligence depending on her care decisions. Note that the figure depicts expected accident costs and total accident costs as a function of both the victim's and the injurer's care decisions as both actors can influence the probability of accident occurrence and the magnitude of accident losses in a bilateral accident setting. Given that the victim will choose to comply with the due care level, the injurer will be liable for the total accident losses. Therefore she will choose to take optimal precautions and engage in a correct level of activity that minimizes the expected total costs of accidents. The rule hence induces both accident parties to take a socially optimal level of precaution. However, only the injurer will choose an optimal level of activity. The victim will just need to take due care to avoid liability; therefore, she may engage in the activity too often.

Strict liability with a defense of comparative negligence is another variation of the simple strict liability rule that can induce both accident actors to take optimal precautions (Haddock and Curran

Strict Liability Versus Negligence, Fig. 2 The influence of the victim's care choices on the costs of accidents in a bilateral accident setting

1985). This rule is similar to the previous one with the difference that if the victim is negligent, she will have to bear only the fraction of the accident losses that is in proportion to the amount of care that the victim failed to exercise.

Under a rule of *negligence*, the injurer will take due care to avoid being held liable. If courts set the level of due care equal to the socially optimal level of care, the injurer will exercise socially optimal precaution. Given that the injurer takes due care, the victim will be the residual cost bearer, namely, she will have to pay for the total accident losses as designated in Fig. 2 by the curve TC . Therefore, she will take into account the benefit arising from taking care and engaging in a correct activity level in the form of a reduction in expected accident losses and will choose to exercise a socially optimal level of care y^* and of activity that minimizes total accident costs. Hence, under this rule both actors will exercise optimal precaution. However, only the victim will consider the effect of her activity level on expected accident losses and engage in the optimal level of activity. The injurer will just need to take due care to escape liability and therefore she will only consider her private benefits arising from the activity; she is consequently likely to engage in the activity too often.

The rule of *negligence with a defense of contributory negligence* is a variation of the simple negligence rule. Under this rule a negligent injurer will be able to escape liability if the victim is also negligent. In other words the injurer will have to bear the total accident losses if she fails to take the due care level set by the law and/or by courts

while the victim does. On the other hand, the victim will have to pay for the total accident losses if she does not comply with the due care level y^* set by the law and/or by courts irrespective of whether the injurer exercised due care. It should be noted that contrary to the rule of simple negligence where the court does not have to determine a due care level for the victim, under this rule the court has to set a level of due care for both the injurer and the victim. If the due care level is set by courts to be equal to the socially optimal level of care, then both accident parties will be induced to exercise socially optimal precaution. The injurer will comply to the due care level to escape liability, while the victim will also be motivated to exercise due care to avoid having to bear total accident losses. Under this rule, if both parties are negligent, only the victim will bear the total accident losses compared to the rule of simple negligence under which if both parties are negligent, only the injurer has to pay for the total accident losses.

A variation of the negligence rule that is used to divide the accident losses between the injurer and the victim when both of them have acted negligently is the rule of *comparative negligence*. Under this rule both accident parties escape liability if they comply with the due care level set by the law and/or by the courts. However, if both of them fall short of exercising the due level of care, then each of them will be liable in proportion to her negligence. In this case the court will assign liability by comparing the actual level of precaution with the due care level that each party should have

exercised to avoid being held liable. Under this rule both parties are motivated to comply with the due care level to avoid having to pay for the total accident losses. Hence, if the due care level is set to be equal to the socially optimal level of care, both parties will be induced to take optimal care.

Liability Rules Compared

A comparison of the rules of strict liability and negligence and their variations shows that apart from the rule of simple strict liability, all other liability rules are efficient as they can provide both injurers and victims incentives to exercise optimal precaution that minimizes total accident costs. However, it is also clear that, irrespective of the rule chosen, in bilateral accidents it is not possible to provide both actors with the proper activity incentives. Only the residual risk bearer will compare her private benefit from the activity with the total accident costs; the other actor will compare her private benefit from the activity with the cost of taking due care. The rules of strict liability with a defense can therefore control the activity levels of injurers but fail to control the activity levels of victims (Shavell 1980; Landes and Posner 1987), while negligence rules can motivate victims to engage in the optimal level of activity but do not provide injurers proper activity incentives. It follows that in bilateral accident settings, the choice between the rules of strict liability with a defense and the rules of negligence depends on whose activity level one wants to control, the injurer's or the victim's.

Under the rules of strict liability with a defense, fully compensatory damages will not be necessary to induce the injurer to take optimal precaution. Given that victims will take due care to escape liability, the injurers will have to bear the expected accident losses and therefore will be induced to take optimal care to minimize total accident costs. Hence, damages need not fully reflect all losses but rather be high enough to make taking optimal care a better choice than taking lower or no care. The same will be true under the rules of negligence. Moreover, the problem of inefficient precaution that arises under negligence rules if the due care level is not set to be equal to the optimal level of care will also be relevant for the rules of

strict liability with a defense. Hence, if courts set the due care level for the victim below the socially optimal level of care, the victim will be induced to take inadequate precaution, whereas if the due care level is set above the optimal care level, the victim will be motivated to take excessive precaution. In order to determine what should be the due care level for the victim under a rule of strict liability with a defense, courts will have to consider the injurer's due care level as well, given that in bilateral accident settings the care decisions of both accident parties affect the magnitude of expected accident losses. This implies that the administrative costs of trial will be of a similar magnitude for both the rules of strict liability with a defense and the rules of negligence. Under both types of rules, courts will have to determine if the injurer and/or the victim is negligent by examining whether her level of care fell short of the due care level. Under a simple negligence rule, the court will have to determine if the injurer complied with the due care level, while under a negligence rule with a defense, the court will additionally have to determine if the victim complied with the due care level. The same will be true for the rules of strict liability with a defense, under which the court will have to set the due care levels for both the victim and the injurer but will only need to determine what was the victim's actual level of care. Therefore, in a bilateral accident setting, a simple negligence rule will impose the lowest cost per trial, whereas under a rule of strict liability with a defense, the cost per trial will be lower than under a rule of negligence with a defense.

Accidents Occurring Under a Preexisting Market Relationship

The same analysis of liability rules, albeit with some variations, holds also for accidents where parties have a preexisting market relationship such as accidents occurring as a result of a defective product. A critical factor is whether consumers (victims) are aware of the risk level of the product. If they have perfect knowledge of the risk, all rules of liability will lead to optimal care levels because the knowledge of the risk induces consumers to take optimal care, and the

force of the market drives firms (injurers) to take optimal care so as to be able to offer their product at the lowest full price, consisting of the market price and the expected accident losses. If consumers perceive the product risk correctly, then under a rule of *negligence*, consumers will regard as full price the price offered by the producer plus the expected accident losses they expect to bear themselves. Therefore, consumers will choose to exercise optimal precaution. Under a rule of *strict liability*, the price offered by the producer will already be the full price, as it will incorporate the accident losses the producer is expected to bear in the occurrence of an accident. Under both liability rules, the producer's costs of care will be included in the offered price. If however consumers are not aware of the product risk, then only *strict liability with a defense of contributory negligence* creates optimal care incentives, as in this case firms will take optimal care to minimize the expected total accident costs and consumers will take due care irrespective of their perception of the risk to avoid being held liable and having to bear the accident losses. It is important to note that the analysis of liability rules in product-related accidents changes somewhat depending on the type of the product. If the product is a service or a nondurable, the analysis above remains valid. However, if the product is a durable, then besides inducing the consumer to take due care, it will also be important to induce the consumer to engage in the optimal activity level (Shavell 1987, 2004). This may occur only under a rule of negligence if the consumer has a perfect knowledge of the risk because then the consumer will be the residual risk bearer, which will induce her to engage in optimal activity. If the consumer is not aware of the product risk, no liability rule will induce her to engage in the optimal activity level.

Strict Liability Versus Negligence and Related Topics

The rules of strict liability and negligence can be further differentiated based on their ability to create optimal incentives under special accident conditions. The rule of negligence, for instance, is,

under certain conditions, considered to be more appropriate than strict liability for cases where the injurer is judgment proof, meaning that her wealth does not suffice to cover accident losses (Shavell 1986; Dari-Mattiacci and De Geest 2005). This is so because an injurer who is unable to pay for total accident costs will have no incentive to take optimal care under a rule of strict liability but may be induced to take optimal care under a negligence rule provided she has enough wealth to afford optimal precaution because in that case she will escape liability. Both rules of strict liability and negligence will create injurers optimal incentives in cases where multiple injurers cause an accident jointly (Landes and Posner 1980; Kornhauser and Revesz 1989). However, only the rule of negligence will induce injurers to take optimal care in cases where multiple injurers cause an accident independently. In that case, under a rule of negligence, each injurer will assume that other injurers will take optimal care and therefore will be induced to take optimal care to avoid liability. On the other hand, taking optimal care under a rule of strict liability will only reduce each injurer's expected accident losses by a fraction, and hence injurers will not be motivated to take optimal care. An additional advantage of the negligence rule is that it generates information regarding safety technology (Schäfer and Müller-Langer 2009). Under a rule of negligence, firms will disclose information on their private cost levels to courts in order to enable them to determine the due level of care. The dissemination of the resulting court decisions will provide other firms valuable information on safety technology free of charge.

The preceding analysis clarifies that from a Law and Economics point of view, the choice between the rule of strict liability, the rule of negligence, and their variations in a given accident setting depends primarily on their ability to create accident parties incentives leading to the minimization of total accident costs. Litigation costs involved with the application of each rule also play a role as to which rule is most desirable. Provided that courts are able to assess damages correctly and that law and/or courts can set the due care level equal to the optimal level of care, it is

concluded that strict liability is a better liability rule in a unilateral accident setting because it induces the injurer to take optimal levels of care and activity. In bilateral accident settings, all liability rules apart from simple strict liability create optimal care incentives to injurers and victims. However, no rule can induce both actors to engage in the optimal activity level.

Today, the rule of negligence is the most commonly used rule of tort liability. The rule of strict liability (with a defense of contributory negligence) is also employed, most notably in cases where it is important to control the care and activity level of the injurer as is the case with product liability and environmental liability.

Subjective Punishment

Josef Montag^{1,2} and Tomáš Sobek³

¹International School of Economics, Kazakh-British Technical University, Almaty, Kazakhstan

²Faculty of Law, Charles University, Prague, Czech Republic

³Faculty of Law, Masaryk University, Brno, Czech Republic

Abstract

A punishment implies some discomfort for its recipient – else it would not punish. Indeed, criminal justice can be viewed as an intricate system that calibrates the severity of

punishment – and therefore the amount of the associated discomfort – to individual offenses and offenders. This is done primarily by adjusting the nominal size of punishment, given by the length of a prison sentence, the number of hours of community service, or the amount of a fine. However, the discomfort from a punishment is codetermined by a host of other factors, such as differences across prison facilities, judicial delays, the punishee's psychological setup, her wealth, luck, family relations, and so on. It is the *interaction* of the nominal punishment with these subjective factors that determine the total amount of discomfort that a punishment creates in a punishee. "Subjective punishment" (or individualized sentencing) is an umbrella term for a variety of theories that suggest these factors should be accounted for when courts decide on a punishment. Their common denominator is that – in order to maintain the equality of the (total) punitive effect for the same crime – they often imply that different offenders should receive different nominal punishment. This essay aims to provide a broad overview of these theories and their potential implications for criminal justice.

Introduction

The primary purpose of criminal sanctions is to give individuals incentives to avoid actions that are socially undesirable, or to reduce the extent of such activities, in other words to deter. In this sense, sanctions are the opposite of rewards, which give individuals incentives to do something socially desirable. For sanctions to be effective in achieving deterrence, their implementation must be associated with a discomfort, or utility reduction, experienced by the recipient. A fine, for instance, effectively reduces an individual's disposable income and thus the amount of goods and services she can afford to buy, lowering her utility. A prison term prevents an individual from undertaking actions, legitimate or otherwise, she would choose to undertake if at large, again resulting in lower utility.

Importantly, this utility reduction from sanctions is fundamentally a subjective phenomenon. As a result, the discomfort from a certain punishment is likely to vary across individuals. In this essay, we try to take a bird's eye view and look at the major factors that generate variation in punishment, other than the sentence pronounced by a court. In particular, two main sources of this variation are relevant to our discussion: (i) differences in the punishees' personae, that is their ability to cope with, or to "absorb," a particular punishment; and (ii) idiosyncratic circumstances that are external to the punishment itself but interact with it. An example of such an idiosyncratic factor is a time lag between the punishment and a crime, which results in a variation in the de facto punishment because delayed punishment is less severe due to temporal discounting. An example of individual, or psychological, factor can be differences in time preferences across individuals, which result in differences in the discounted value of a delayed punishment.

A question naturally arises, whether, to what extent, and how should be such variation in the disutility associated with a punishment taken into account when determining punishment in criminal cases. These issues were recently discussed in a series of high-profile law review articles (see, mainly, Bronsteen et al. 2009; Gray 2010; Kolber 2009; Markel and Flanders 2010). Our goal in this essay is to summarize the main points, questions, and findings in this debate and put them within the context of the law and economics of crime literature.

In order to keep the ideas focused, we make two qualifications. (i) We abstract from individual variation in the benefits from crime that may produce variation in the social cost of crime and may have implications for the punishment. To give an example, jaywalking by a surgeon on his way to an urgent operation may be socially less harmful (in fact it may be socially beneficial) than jaywalking by a student who is late for her lecture. Whenever we talk about two different individuals committing the same offense, we assume that the offenses are equivalent in terms of the total social costs as well as the offenders' benefits. (ii) When thinking about punishment, we are

mainly concerned with the consequentialist reasons for punishing individuals, particularly with deterrence, and are abstracting from retributivist approaches (see, e.g., Kolber 2009; Gray 2010; Markel and Flanders 2010, for discussion of retributivism and subjective punishment).

Punishment and Subjective Discomfort

The magnitude of the discomfort that any given nominal punishment creates in a punishee is determined by a number of factors other than the formal punishment itself. Wealth is a prominent, and controversial, example of such a factor. A fine of €50 for jaywalking is likely to produce a different amount of displeasure in a person living off unemployment benefits than in a successful rock star. This is because the goods that the rock star would buy for those €50, such as a pair of luxury socks, would be probably less valuable to her than the value to the unemployed of the goods she would purchase for her €50, perhaps a winter jacket. As a result, the utility reduction produced by this fine may differ across the two offenders. By the same token, however, a prison term may generate different amount of discomfort in a wealthy individual from say a homeless person. This is because the change in lifestyle, the opportunities forgone while incarcerated, and the postrelease repercussions of incarceration are likely to be different for the two individuals (Kolber 2009).

Wealth is not the only determinant of the discomfort an individual punishee experiences, however. Individuals' ability to adjust to prison might vary, for example, a claustrophobe is likely to suffer in prison more than an inmate without such a condition. Some prisons may be better than others in terms of food, wards treatment of prisoners, safety, or hygiene.

These idiosyncrasies in severity of the actual punishment as experienced by the punishee are inherently problematic since they imply that individuals who committed the same offense and receive the same sentence may eventually be punished differently. Put differently, individuals will, in reality, face different *de facto* sanctions for the same offense. That, in turn, means that

individuals' incentives not to offend differ, which may not be desirable.

Mechanisms Causing Variation in De Facto Sanctions

Wealth

As already noted, offenders' wealth affects the severity of monetary as well as nonmonetary sanctions. This is because a sanction can cause different amount of utility reduction, depending on individual's wealth. However, wealth also affects the ability to pay a fine, which has important implications for deterrence. Take an extreme example of a potential offender who possesses zero wealth. As a consequence, the maximum fine such an offender can pay is also zero – no fine generates any deterrence for such an offender. Because deterrence produced by monetary sanctions is clearly limited by offenders' wealth, low wealth offenders may be underdeterred. This has important implications for the design of penal system. Specifically, optimal fines and prison sentences may vary with wealth, at least in theory.

To see this, note a well-known theoretical result by Becker (1968) stating that fines should be as high as possible, that is equal to individuals' wealth, in order to allow for minimal enforcement intensity. At the same time, incarceration should be used as sparsely as possible. This is because law enforcement and nonmonetary sanctions are socially costly, whereas monetary sanctions are just transfers of money from offenders to the state. Whenever a fine can be increased and the probability of apprehension decreased while keeping the expected sanction (and thus deterrence constant), doing so increases social welfare, for fewer resources will be necessary for law enforcement in order to achieve the same crime rate.

This result, however, breaks down when individuals differ by wealth (Polinsky and Shavell 1991). Suppose there is only one type of crime that people commit and all potential offenders are the same, except for their wealth. Initially, a fine is in place that is equal to the total wealth of low-

wealth individuals. Then increasing the fine and lowering the probability of apprehension may result in the same expected sanction for high-wealth individuals, but will result in a *lower* expected sanction for low-wealth individuals, since for them the fine remains the same (equal to their entire wealth), while the probability of conviction decreases. When nonmonetary sanction is available, it is optimal to set fine equal to the total wealth of high-wealth individuals and possibly supplement it with nonmonetary sanction (Polinsky and Shavell 1984). Wealthy offenders will then pay high fine and bear low prison sentence while low-wealth offenders would pay low fine and face more severe prison sentence (Polinsky 2006).

Punishment Lag

Another important source of differences in the severity of punishment is judicial delays. A 12-month sentence that commences, say, 7 years after the crime is very different from a 12-month sentence that commences within a year. This is especially true from the *ex ante* perspective, that is when a decision as to whether commit a crime or not is being contemplated. The effects of delays on the *ex ante* punishment severity are magnified by the fact that criminals tend to discount future more heavily (Åkerlund et al. 2016). More specifically, Mastrobuoni and Rivers (2016) estimate the average yearly discount factor among criminals to be about 0.75.

We illustrate the implications of temporal discounting on sentence severity with the help of a simple model and a numerical example. Consider an individual contemplating whether to commit a crime that would carry a 12-month jail sentence if she is caught. Suppose that S is the value to her of the discomfort from a 12-month prison sentence in case it would commence immediately. The probability of apprehension is fixed and equal to P and let D denote the delay, measured in years, between the day of the crime and the commencement of the prison term. Finally, define the “certainty equivalent of an instantaneous prison sentence” (CEIPS) as the amount of discomfort associated with a hypothetical prison sentence that would commence

immediately after the crime and with 100% probability. CEIPS thus represents the cost of a potential future prison sentence to an offender in terms of a prison sentence that she would begin to serve immediately and is equal to

$$\text{CEIPS} = 0.75^D \cdot P \cdot S,$$

using Mastrobuoni and Rivers’ (2016) estimated discount factor and assuming, for simplicity’s sake, that the offender is risk neutral (and time-consistent). For an offender who is to start serving a 12-month sentence today, CEIPS is simply equal to S . Note that CEIPS is the relevant quantity that enters into the criminal’s determination whether to commit a crime or not, i.e., it is the *ex ante* cost of criminal punishment to the criminal that can be avoided by not committing the crime.

Suppose that about two-thirds of offenders are captured and convicted, i.e., the probability of conviction is $P = 2/3$. As a result, in case of instantaneous conviction, that is when $D = 0$, CEIPS is equal to $(2/3) \cdot S$, which is equivalent to receiving 8 months in prison starting immediately. Now consider a case in which it takes a year to convict a criminal and send her to prison, i.e., when $D = 1$. The implied CEIPS will be $0.75 \cdot (2/3) \cdot S = S/2$, i.e., 6 months in jail. However, court delays are in some cases are much longer. If, for example, the time to conviction is equal to 7 years, that is when $D = 7$, then the associated CEIPS will be $0.75^7 \cdot (2/3) \cdot S = 0.09 \cdot S$, just a little more than 1 month in prison. In other words, a prison sentence delayed by 7 years is worth one-sixth of the same prison sentence that would begin 1 year after the crime.

Judicial delays therefore significantly limit the deterrence that the system of criminal law provides. At the same time, judicial delays may vary from case to case. As a result, two criminals that receive formally equivalent sentence may receive very different de facto punishment, if one is sent to prison quickly and the other with a lag.

In order to compensate for these disparities, Listokin (2007) proposes maintaining constant discounted sentencing terms by adjusting individual sanctions to account for the lag between crime and punishment. By the same token, pretrial

detainees should receive “interest” in addition to credit for time served since their sentences begin earlier and have greater discounted values. Equivalent reasoning, of course, applies to monetary punishment. A fine of €100 due 10 years from now is less severe than the same fine that is due right now. Delayed fines should be higher to compensate for their lower discounted value.

Hedonic Adaptation

Another important mechanism affecting the de facto sentence severity is adaptation. A substantial body of psychological research suggests that people tend to adapt to shocks to their life, positive or negative (see Bronsteen et al. 2009, 2014). A few findings of the existing research stand out from the point of view of criminal sanctions: (i) sanctions, monetary or imprisonment, tend to generate a decline in punishees’ well-being; (ii) this is however followed by a recovery so that the negative shock from a sanction tends to be short-lived; (iii) people tend to forget about past experience of adaptation and therefore tend to overestimate the effects of future shocks to their well-being; (iv) the postrelease effects of prison experience, in the form of poor health, economic effects from the stigma, or worsened family relations generate long-term losses to ex-prisoners’ well-being that are difficult to adapt to.

The patterns of adaptation while in prison and postrelease effects of prison have profound consequences for how punishment affects individuals. As Bronsteen et al. (2009) point out the fact that individuals fail to anticipate adaptation suggest that the social cost of imprisonment is lower than previously thought. This is because adaptation mitigates the losses in punishee’s well-being during incarceration while the individuals’ tendency to ignore this effect mean that punishment retains its deterrent power.

At the same time, these findings may have important implications for the trade-off between fines and imprisonment. If individuals adapt to the negative shock from fines and if they fail to anticipate this pattern, fines too are socially less costly than they would be in the absence of adaptation, while keeping their deterrent effect. To the extent there are other costs related to incarceration itself and the postprison effects on individuals’ well-

being are substantial (for they tend to occur over a longer timespan than the prison sentence) the social costs of incarceration are increased. In addition, these long-term effects may not generate much deterrence due to discounting of future events, as discussed above. On the balance therefore, the economic case for monetary punishment may be stronger than previously thought.

Health

Individuals have different physical and psychological setup. This in turn implies differences in their ability to cope with a punishment. A claustrophobe may not be able to adapt to prison confinement as easily as a person without such condition and so may suffer in prison more. A physically weak punishee may be more likely to become a victim of prison violence, rape, or exploitation. Even in the absence of actual violence, its increased likelihood may put individuals under increased strain.

Additionally, being a prisoner is not a healthy lifestyle (Fazel and Baillargeon 2011). The prevalence of diseases such as HIV, Hepatitis, and Tuberculosis imply a higher risk of infection faced by prisoners. Prisoners also exhibit higher rates of mental disorders and higher suicide rates, particularly among women and juveniles. Importantly, the impact of prison on health does not cease upon the release. Exprisoners suffer from increased prevalence of infectious and stress-related diseases (Massoglia 2008a, b). All of these factors generate differences between individual offenders in the amount of discomfort from a punishment.

Subjective Effects of Other Types Sanctions

The subjective punishment considerations are not limited to incarceration and pecuniary penalties. A variety of other types of punishments are prescribed for various types of crimes, examples include death penalty, community service, shaming punishments, or revocation of driver’s license. The severity of all these types of punishments is codetermined by subjective factors on the side of convicted persons.

Consider perhaps the most severe type of punishment, the termination of the offender's life. A significant element of the punishment from death penalty is the loss of the rest of life. However different people may have a different expected length of life. The life expectancy of young people is larger than that of old people. Moreover the quality of life is reduced by chronic illnesses typical of old age. Therefore the capital punishment is likely to be more severe for a young person than for an old one (see Alberini and Ščasný 2011, for evidence of individual-level heterogeneity in the valuation of life).

Similarly, in the case of community service that can be more burdensome, symbolically or physically, for a white collar senior compared to a blue collar young man. The symbolical burden may be however diminished, possibly to a larger degree for the blue collar worker, by the fact that the service for the public good may not be viewed as shameful. The so-called shaming punishment is a type of alternative sanction whose purpose is to satisfy a popular expectation that punishment expresses an authoritative moral condemnation (see Kahan 1996, for a debate of alternative sanctions and shame). A thief is ordered, for example, to publish his photo with his full name together with a moralistic or self-degrading commentary. However the severity such a sanction will again substantially depend on individual punishee's circumstances. The same punishment may carry much more shame in a village community than in a big anonymous city. It may or may not result in a reputation damage, depending on the actual reputation a punishee possesses.

Potential Benefits of Tailoring Sanctions

Recognizing how nominally equivalent punishment may generate different amounts of discomfort in different punishees is relatively straightforward. Whether and how these factors should enter into the determination of punishment is a more complicated question. Indeed, the United States Sentencing Guidelines Manual discourages judges from calibrating sentences based on convicts' subjective experience (Kolber 2009).

While clearly controversial (see, e.g., Gray 2010; Markel and Flanders 2010), the idea of tailoring sanctions to individual offenders is theoretically appealing. Suppose courts are perfectly informed, that is they have exact knowledge of offenders' benefits from an offense as well as the costs to her from a sanction. Then, if a court could *ex post* set a sanction in each case so that the sanction-related costs to the criminal exceed the benefits from the crime she may have received, each offender would be perfectly deterred. As a result, no sanctions would have to be implemented and crime level would be zero (Shavell 1987).

That may sound like a theoretical possibility, however one can expect that with the progressing scientific knowledge and advances in technology, our ability to measure the discomfort associated with punishment as well as to estimate the benefits from a crime should also improve. We are already beginning to be able to see and measure the neural processes associated with pain and pleasure, although the resulting data are still highly imperfect and their usability at court is limited as of now (see, e.g., Brodersen et al. 2012; Miller 2009; Schulz et al. 2012; for philosophical discussions about advances in neuroscience and the law see Greene and Cohen 2004; Morse 2006, 2011). In the future, however, these developments will inevitably lead to an important dilemma faced by the criminal justice, namely, to what extent should such information be taken into account when determining a criminal punishment?

Experimental Evidence

While legal scholars debate to what extent should the subjective factors be accounted for by the criminal law and sentencing practice, a natural question arises as to whether such legal innovation would conform with people's preferences toward punishment and their view of justice. This question is relevant because for criminal justice to function properly and generate the desired consequences, criminal law and practice should be clear, well understood by its subjects, and should not contradict the common sense of what is just. Two experimental studies designed to

shed light on this question have been recently conducted.

In Montag and Sobek (2014), we run a vignette experiment in which about 200 subjects, mostly business or economics undergraduates, were asked to decide on a hypothetical punishment for a convicted defendant. The subjects could choose any combination of fine and a prison sentence. Each subject was presented with a sequence of two cases, one at a time, and provided stylized facts about each case. The two cases differed from each other only, but significantly, in the wealth of the defendant. In addition, the sequence was randomized across subjects so that one half first received a case with a poor defendant, after which they were presented with the same case featuring a rich defendant. For the second half of the participants, the order of cases was reversed.

This experiment thus generated two types of variation: (i) within-subject variation, when comparing the punishment for the poor with the punishment for the rich assigned by each subject; and (ii) between-subject variation when the decisions of the group that first received the case featuring poor defendant are compared with the decisions of the group that first received the case with rich defendant. Both sources of variation allow us to look at the relationship between wealth and punishment, but with a slightly different interpretation. The within-subject variation is essentially telling us what is the explicit *rule* that the subject would adhere to – under the assumption that their first decision is a precedent, i.e., it is binding when subjects are deciding their second case. The between-subject variation, i.e., comparing the first decisions of the two groups, allows us to look at subjects' "gut feelings" about the appropriate punishment, since this decision is done in the absence of any precedent.

The within-subject results suggest that a slight majority of subjects, about 55%, would give higher fine to a wealthier defendant. At the same time, a vast majority, 87%, assigned the same prison sentence to both defendants, strongly rejecting the notion that rich defendants could receive shorter sentences. In addition, the rules elicited via within-subject variation were highly

consistent with the between-group results: the subjects that first received the rich defendant assigned higher fines on average than the group who first had to punish the poor defendant. However, both groups assigned the same average prison sentence in their first decisions. These results suggest that the subjects had a rather consistent notion of whether and how wealth should enter into the determination of criminal punishment.

However, vignette experiments are subject to criticism due to the absence of incentives. Furthermore, the subjects' decisions in this experiment had no consequences, the punishments assigned were purely hypothetical. At the same time, it is also possible that the subjects did not perceive wealth as a cause of potentially differential effects of prison on the punishee.

Montag and Tremewan (2016) therefore run a laboratory experiment that aims to address these criticisms. The "crime" in this experiment consists of subjects decision whether to take back a donation to a charity (the Red Cross) that would be otherwise subtracted from their earnings at the end of the experiment. They run six experimental sessions with two treatments, monetary and non-monetary: In the monetary treatment, the punishment is a fine between €0 and €5 subtracted from subjects' earnings in the experiment. In the non-monetary treatment, the punishment consists of the punishee having to place between 0 and 100 sliders displayed on the computer screen exactly in the middle (using mouse only) at the end of the experiment.

Importantly, the authors elicit subject's willingness to pay, i.e., the maximal amount each subject would be willing to pay, to avoid placing the sliders. This is a measure of subjective discomfort associated with placing sliders. During this elicitation, the subjects earned between 0 and €5, depending on how quickly they place 100 sliders. In addition, subjects receive a random payment of 0 to €5. So there are two sources of income: earned and a windfall.

Then the punishers were matched with punishees and given three pieces of information: the punishee's willingness to pay to avoid placing the sliders, her earned wealth, and her random wealth. This allows looking at the role of these

factors as punishment determinants. The results of the experiment suggest that that people tend to apply higher fines to wealthier individuals and assign fewer punishment sliders to those with a higher willingness to pay to avoid this tedious task. These results generally seem to support the notion that subjective discomfort should enter into punishment determination.

Summary

Every criminal justice system faces a trade-off between the principle of systemic consistency and the premises of individualized justice. The former demands equal treatment before the law, rule-guided judgment, predictability, and legal certainty. The latter holds that judges need some measure of discretion and flexibility because they should impose sentences that are appropriate according to relevant circumstances of particular case. However, the two principles may not be in conflict once it is recognized that nominally equal treatment may lead to treatment that is unequal de facto.

Legal scholars have recently proposed that improvements in scientific knowledge and advancements in technologies (such as functional magnetic resonance imaging), which allow us to measure subjective perceptions and feelings, need to be and should be incorporated in our penal systems. This would facilitate calibrating the punishment not only for the crime but also to the offender's persona, so that different people experience equally tough punishment for the same crime. These developments raise a number of interesting questions as to the nature, the purpose, and possibly the future of punishment.

The experimental evidence available so far suggests that in the case of monetary punishment, calibration to the individual punishee's circumstances may well conform to people's perception of justice and punishment. In the case of non-monetary punishment, the results are rather inconclusive. More research is required in order to better understand the costs and benefits of accounting for subjective factors in punishment determination.

to strengthen the accountability, transparency and integrity of government and public sector entities as well as to make a difference to the lives of citizens. Moreover, SAIs should notify policy makers of the emerging trends and future challenges in order to help them to take action to avoid crises. Despite their differences and various models from country to country, SAIs are often mentioned as “*watchdogs*” or “*cornerstones of transparency and accountability*” of public financial management and they constitute essential components in a democratic system.

Definition

Each country has a supreme audit institution (SAI), which is responsible for exercising oversight over government revenues and expenditures and publishing an annual report to inform the parliament and the public.

These institutions are organized according to different models (i.e., Anglo-Saxon model (National Audit Office), Court of Accounts (Cour des Comptes), etc.), which reflect the different policies and systems of governance and different regimes and cultures of each country. Despite their differences, their main objective is to oversee the management of public funds as well as the quality and reliability of financial data included in the reports addressed to governments.

Supreme Audit Institutions

Abstract

Supreme Audit Institutions (SAIs) are independent external services charged with the audit of public funds. Their main objective is

Introduction

Public expenditure in a democratic society should rely on an effective financial management and control system. “SAIs help the executive to make the best possible use of public funds, in other words to ensure that the political objectives of the expenditure are achieved at a minimum cost and that the accounts drawn up are transparent. Furthermore, the publication of audit findings enables citizens to become familiar with and to legitimise the actions of their government and representatives” (Vallés 2005, Foreword, p. xi).

According to the International Standards for Supreme Audit Institutions (ISSAIs), SAIs are external audit services and do not constitute part of the organizational structure of the audited entities (INTOSAI, ISSAI 1, Sect. 3, § 1). Their legal mandates, reporting relationships and effectiveness, vary, reflecting different governance systems and government policies (Stapenhurst and Titsworth 2001).

However, each country has the choice of its own SAI model, and the way in which it operates varies greatly from one country to another.

Theoretical Framework

SAIs vary according to the different legal, financial, and political traditions of each country. Although the literature mentions several categories of SAIs, according to ISSAIs (1000, § 47), the three most common systems are:

The Jurisdictional Model (Napoleonic System or Court of Accounts)

In this system, the SAI, also known as the Court of Accounts (Court of Audit), is a judicial and administrative authority independent of legislative and executive powers. The SAI is an integral part of the justice system, making judgments on government compliance with laws and regulations and ensuring that expenditures are justified.

According to this model, the SAI is an integral part of the judicial system functioning independently of the executive and legislative powers. One of the main differences of the judicial model is the fact that public officials are normally held personally responsible for any unauthorized or illegal payments in installments. The Court of Accounts is competent for imposing penalties where illegal transactions are found.

Under judicial models, the SAI often has significant independence from the parliament. Susceptibility to political influence should be relatively low through this arm's length relationship but depends on the autonomy of the judiciary and the specific terms of tenure for judges. A potential incentive problem can arise in

circumstances where financial penalties imposed flow to the court itself rather than back to central government budgets (Clench 2010).

Judicial systems traditionally concentrate on compliance with detailed rules and regulations to ensure that money has been properly spent. However, there is often less focus on wider financial management issues relating to the economy, efficiency, and effectiveness of expenditure (Blume and Voigt 2011).

The drawbacks include that the system is inherently complex and can be difficult to operate effectively if there is limited human capacity (in either numerical or knowledge terms) or a lack of other resources. In such circumstances, controls may be applied mechanistically or not applied at all. This model is widespread in countries that have a French legal origin and is followed in France, Italy, Spain, Portugal, Brazil, Belgium, El Salvador, Turkey, Greece, and in most Francophone and Latin American countries (DFID 2004).

The Anglo-Saxon Model (Westminster Model or Monocratic Model or Auditor General-National Audit Office Model)

In this model, the SAI is headed by a single auditor general (comptroller and auditor general – C&AG) and often acts as an auxiliary body in the parliament. The Office of the Auditor General is an independent body reporting to the parliament, namely, the parliamentary committee (PAC). Traditionally, the head of the PAC is a member of the opposition (Blume and Voigt 2011).

With one individual at the top of the SAI, power is considerably centralized. As a result, much of the integrity of the institution rests on the credibility and personal motivations of the auditor general. However, susceptibility to political influence should generally be low, given that the auditor general answers to the legislature as a whole, and typically cannot easily be removed from office (Clench 2010).

The Office of the Auditor General does not have legal competence, but when necessary, the results can be transmitted to the judicial authorities for further investigation (Stapenhurst and

Titsworth 2001). Its priority is to provide support to the parliament and secondarily to provide assistance to judicial institutions.

The Westminster model has a strong focus on financial audit and on the value for money with which audited bodies have used their resources, with less emphasis on compliance with detailed legislation and regulations (DFID 2004). This model focuses much more on financial aspects than the Napoleonic model.

It is widespread in Anglo-Saxon countries, the United States, Australia, India, the United Kingdom, Canada and Latin America, Chile, Colombia, Mexico, Peru, in several Caribbean and Pacific countries, and in English-speaking African countries.

The Collegiate Model (Board Model)

In this model, the emphasis is on the collective decisions of the organization, but without legal responsibility. Its main task is to analyze public revenue and expenditure and to present the report on its findings to the parliament.

The basic structure of an SAI's relationship with the parliament, the government, and the administration is very similar to the Westminster model except for the internal structure of the audit institution. This system is independent of the executive and assists the parliament in the exercise of oversight but is not managed by a single person (as in the Westminster model) but by a board made up of several people who make decisions on operations and management by consensus (Clench 2010; Blume and Voigt 2011). This can be both an advantage and a disadvantage: the result of the work does not depend so much on one person, but on the other hand, its collective structure can lead to a complex and slow decision-making process. Clench (2010) mentions that depending on the degree of autonomy of each board member, there is a potential for multiple and conflicting interests. This can undermine the consistency of auditing across different government bodies with difficulties in imposing minimum standards. These risks can be minimized by the use of international standards that may be a point of reference for achieving consensus across the board.

This model is very widespread in Asia, Indonesia, Japan, Argentina, and the Republic of Korea.

Discussion

Generally, the Napoleonic model is more common in countries where the system has a French legal origin and the Westminster model in countries where the system has a common law origin, but it is also widespread in countries such as Chile and Peru, which, although included in the French system, have SAIs following the Westminster model (Blume and Voigt 2011).

Santiso (2006) points out the most important differences between these models, which include:

- Time of the audit: (ex ante or ex post audit)
- The nature of the audit: if the SAI focuses on compliance or performance (audit performance)
- The effects of the audit: (follow-up of audit recommendations)
- Their status: (the legal status of audit decisions)

The OECD mentions that the two major types of SAIs are generally described as "courts" and "offices." However, in practice, SAIs are unique hybrids that do not easily fit into a traditional separation of powers and can combine various elements of these models.

Given above, it is obvious that in the field of external public financial auditing, almost every country has a unique system, different even from the country that seems closest to it in terms of norms.

Abstract

This entry discusses the economics of eminent domain, which is the government's power to take or regulate privately owned property for the common good. It discusses the origins of the power as well as its limits, particularly as embodied in the public use and just compensation requirements. It also reviews the economics literature on how eminent domain affects incentives for efficient land use.

JEL codes: K11, K32

Definition

Takings: The acquisition of privately owned property by the government using its power of eminent domain.

The right of the community to exercise eminent domain and thereby expropriate individually held property for the common good seems to have been universally acknowledged and practiced by societies throughout history. As Reynolds (2010, p. 11) asserts, "...the principle that land might

be taken from individuals when the community needed it has been so generally accepted that it did not need to be stated or argued about until recent times." For example, the very phrasing of the Takings Clause in the US Constitution, which states "nor shall private property be taken for public use, without just compensation," implicitly acknowledges that governments have the right to take property; its main purpose is to limit that power by requiring that the taking be for a public purpose and that just compensation be paid.

The idea that compensation should be paid when land is taken also has ancient roots and is therefore taken for granted in the law of most countries. Even in communist China, where land is collectively owned, the 1982 Constitution provides for farmers to receive compensation for "use rights" (as proxied by crop yield) when their land is taken in the "public interest." In cases of physical takings, the debate about compensation has always been about the *amount* of compensation that should be paid, not about whether it should be paid. However, the question about the specific meaning of "common good" or "public purpose" seems to be primarily an issue in American law and likely reflects the explicit inclusion of "public use" as a limitation on eminent domain in the US Constitution.

Takings questions also arise in contexts where land is not physically taken, but its use is restricted in some way, for example, through land use regulations. Such regulations are often termed

“regulatory takings.” In addition to the provisions for compensation for acquisitions under eminent domain, laws governing compensation for land use regulations exist in most countries, though they tend to vary greatly in the rights to compensation that they afford. In a study of 13 countries, including the USA, Canada, several European countries, Israel, and Australia, Alterman (2010) found a range of compensation rights, from very little to nearly full, with the USA lying in between. Notably, there seems to be no way to correlate a country’s laws with its geographic, legal, demographic, or other attributes.

From a theoretical perspective, the issue of eminent domain has generated an enormous amount of legal scholarship and case law. Much of the discussion focuses on the meaning of the “public use” and “just compensation” requirements in the US Constitution, which together restrict the scope of government acquisition of private property. However, the economic questions regarding the appropriate limits on the power to take property or restrict its use are relevant in all countries where governments are granted these powers. The economic literature asks whether there is an economic rationale for bestowing the right to acquire property or restrict its use without the owner’s consent on the government alone (and not on private parties) and seeks to understand the limits of that right, as embodied in the public use and just compensation requirements. The primary focus is on how granting and restricting that right affects incentives for efficient land use.

Public Use

On its face, a public use requirement would seem to limit the use of eminent domain to provision of public goods like highways, airports, or parks. This interpretation is appealing both in terms of the plain meaning of the phrase “public use” and in view of the well-accepted role of the government in providing these types of goods. Specifically, because public goods have the characteristic of non-excludability, meaning consumers can enjoy the benefits of the goods without first

having to pay for them (i.e., to free ride), ordinary markets will underprovide them. Economists have long argued, therefore, that the government should provide public goods so as to ensure that the efficient quantity will be supplied and then use its tax powers to coerce consumers to contribute to the cost. In this sense, government provision and financing of public goods amount to a kind of “forced purchase” by consumers. Merrill (1986) refers to the proposition that the government alone should have the power of eminent domain and should only use it to provide public goods, as the “ends approach” to defining public use because it concerns the use to which the taken land will be put (also see Miceli (2011), Chap. 2).

The logic of the ends approach, however, does not explain why the land (and possibly other inputs) needed to provide a public good must also be forcibly acquired from the owner(s). The economic justification for this form of coercion, which involves a “forced sale” from input owners to the government, is a different kind of market failure, referred to as the holdout problem. The holdout problem arises in the context of any development project requiring the assembly of multiple contiguous parcels of land. The difficulty developers face in this context is that once the scope of the project becomes public knowledge, individual landowners acquire a kind of monopoly power, given that each parcel is essential for completion of the overall project. Imagine, for example, a road or railroad builder who has decided on the optimal route and has assembled several parcels. Refusal of any additional owners to sell would greatly increase the cost of the project, and as a result, all owners can hold out for prices above their true valuations. The likely result is underprovision of projects involving assembly (Miceli and Segerson 2012). One solution to the holdout problem is to take away an owner’s right to refuse a sale at the offered price. The power of eminent domain represents such a forced sale at a price set by the court. Merrill (1986) refers to this justification for eminent domain – i.e., as a response to the holdout problem – as the “means approach” to public use because it concerns the manner by which land for a government project is acquired.

From an economic perspective, the ends approach is the correct justification for eminent domain, but that does not mean that it is the correct interpretation of the “public use” requirement. The reason for this paradox is twofold. The first derives from the fact that the holdout problem and the attendant inefficiencies are not unique to public projects. Private developers also face holdouts for large-scale commercial developments, as do local development authorities undertaking urban renewal. In some cases, private developers can mitigate the problem by means of secret purchases (Kelly 2006), but at some point the scope of the project becomes apparent, and the holdout problem arises. The logic of the above argument therefore implies that, from an efficiency perspective, the power of eminent domain should be available to any developer, private or public, engaged in land assembly.

Second, in explicating the constitutional basis for a public use requirement, courts routinely invoke the ends approach by appealing to the “public purpose” behind the project in question. This is an easy argument for truly public goods because the benefits of the resulting project are available to all, but the logic is less persuasive when the project is largely private, as has been true in most US Supreme Court cases involving the public use issue. For example, in the case of *Kelo v. New London*, despite the fact that the primary beneficiaries were private businesses, the US Supreme Court upheld the city’s use of eminent domain to assemble land for purposes of a redevelopment project by emphasizing the jobs and enhanced tax revenues that would materialize from the project (125 S. Ct. 2655, 545 U.S. 469 (2005); also see Merrill (1986) and Kelly (2006) for a discussion of other notable cases in this vein). As Merrill (1986, p. 67) notes, however, this strategy is not unusual, as courts strain to make their reasoning consistent with the plain meaning of the US Constitution. The difficulty in defining the public use requirement therefore comes down to a divergence between the economic and legal justifications for eminent domain. Whereas economists focus on the use of eminent domain as an efficient response to the holdout problem, regardless of the context,

courts often emphasize the need to identify some public benefits as flowing from the use of government coercion.

Just Compensation

A second requirement for the use of eminent domain is generally that the landowner must be paid “just compensation.” Although no further definition of what amount of compensation is “just” is given, courts have typically interpreted it to mean “fair market value.” Economists, however, argue that this measure systematically undercompensates owners because it ignores their “subjective value” (Fischel 1995a). The idea can be easily illustrated in a simple supply-and-demand diagram for some particular category of land (Miceli and Segerson 2007, p. 20) (Fig. 1).

In the graph, the demand curve represents the willingness to pay for individual parcels of land by potential buyers, while the supply curve represents the reservation price, or opportunity cost, of current owners. The equilibrium price, P^* , can be interpreted as the market value of a unit of the land in question, reflecting the price of recently sold parcels. Note that the price partitions the market into the parcels that are sold over some time period (those between 0 and Q^*) and those that are not sold (those to the right of Q^*). In other words, owners between 0 and Q^* voluntarily sold because the price exceeded their opportunity cost,

Takings, Fig. 1 Subjective value

but those to the right of Q^* did not sell because the price was below their opportunity cost.

Now suppose that one of the parcels to the right of Q^* is taken by the government for use in a public project, necessitating the payment of just compensation. In order for the transaction to be consensual on the part of the seller, compensation would have to be set at or above the relevant point on the supply curve. The problem with this “value-to-the-owner” measure of compensation is that it is a private information of the seller and therefore can be misrepresented, thus creating the risk of a holdout problem (Knetsch and Borcharding 1979). Market value, in contrast, is observable but clearly undercompensates owners, with the difference between market value and value to the owner representing the owner’s subjective value, as shown in the graph.

Epstein (1985) has argued that the loss that market-value compensation imposes on landowners is only justifiable in two circumstances. The first is when the surplus created by the taking – the difference between the value of the parcel in its new use minus the owner’s opportunity cost – is widely distributed rather than being concentrated in a few hands. In essence, Epstein is arguing for the ends approach to public use – that is, eminent domain should only be used to provide public goods – for in that case the distributional requirement is clearly satisfied (also see Ulen (1992)). Epstein’s argument is motivated primarily by concerns about distributional equity, but it also reflects the idea that when gains from coerced transactions are dispersed, private interests will not find it worthwhile to engage in rent-seeking efforts to acquire eminent domain power.

The other circumstance in which undercompensation in a monetary sense is justifiable according to Epstein is when the government action provides “in-kind” compensation. An example is a zoning ordinance that deprives owners of some uses of their land, particularly those that would be harmful to their neighbors. Although an owner could claim that this type of regulation prevents him from engaging in certain profitable activities, like opening a gas station in a residential area, that “loss” is calculated based on his unilateral departure from an efficient land use pattern in which all other owners refrain from

engaging in the externality-producing activity. In fact, when all landowners comply with the regulation, and assuming the regulation is efficient, their property values are enhanced relative to a situation in which no regulations are imposed. In this sense, all owners receive in-kind compensation from the regulation and therefore are not entitled to further monetary compensation. This is in contrast to regulations that “single out” individual owners to surrender their land for the benefit of others, in which case monetary compensation is required.

Compensation and Land Use Incentives

The preceding discussion of compensation has focused on its role in limiting excessive takings. However, most recent economic scholarship on eminent domain, especially since the publication of the seminal article by Blume et al. (1984) (hereafter BRS), has been to evaluate the incentive properties of the compensation rule regarding the land use decisions of property owners whose land is at risk of a taking. The incentive effects of compensation can be shown using a simplified version of the BRS model. Specifically, let $V(x)$ be the value of a piece of land after x dollars have been invested in improvements, where $V' > 0$ and $V'' < 0$. Also let p be the probability that the land will be taken by eminent domain, let B be the value of the land in public use, and let $C(x)$ be the amount of compensation paid to the landowner, which may depend on the amount of improvements. Initially, both p and B will be treated as exogenous.

The timing of events is as follows. First, the landowner chooses the level of investment, which is irreversible, taking the probability of a taking and the compensation rule as given. Once x is in place, the taking decision is made. If the land is taken, the landowner is paid compensation and the land is converted to public use. The requirement that x must be chosen before the taking decision occurs is crucial because otherwise, the landowner could simply wait until the taking decision is made and only invest if the land is not taken. (This assumption is not restrictive in the sense that private land is always subject to a taking risk.)

Similarly, the irreversibility of x precludes salvaging the cost of the investment if the land is taken.

In this setting, the socially optimal level of investment maximizes the expected value of the land:

$$(1 - p)V(x) + pB - x. \quad (1)$$

The first-order condition defining the optimal investment, denoted x^* , is

$$(1 - p)V'(x) - 1 = 0. \quad (2)$$

Note that the resulting investment is decreasing as the probability of a taking increases and is generally less than what the owner would invest in the absence of a taking risk, reflecting the fact that any improvements are lost if the land is converted to public use.

The actual level of investment by the owner maximizes the expected private value of the land, which includes the expected amount of compensation:

$$(1 - p)V(x) + pC(x) - x. \quad (3)$$

The resulting first-order condition is

$$(1 - p)V'(x) + pC'(x) - 1 = 0. \quad (4)$$

Comparing this to Eq. 2 shows that $C' \equiv 0$ is necessary and sufficient for efficiency – that is, compensation must be lump sum. Intuitively, compensation potentially creates a moral hazard problem. If, for example, landowners expected to be fully compensated, or $C(x) = V(x)$, they would overinvest because they would ignore the possibility that the land might be taken, which would render any improvements worthless. At the other extreme, zero compensation, or $C(x) \equiv 0$, results in the efficient level of investment. This represents the famous “zero compensation result” from BRS. (Of course, any positive lump-sum amount would also be efficient.)

The conclusion that zero compensation is efficient, however, is at odds both with general notions of fairness and constitutional requirements for just compensation. This raises the question of whether this result would hold under a more realistic depiction of the taking decision. For example, the above

argument assumes that the probability that the land will be taken is independent of its private value. In reality, a government that behaves in a benevolent or “Pigovian” way (see Fischel and Shapiro 1989) will only take land when it is efficient to do so, thereby making the probability of a taking dependent on the landowner’s decision. Suppose, for example, that the value of the land in public use is a random variable whose value is only observed after landowners have made their investment decisions. Upon observing the realized value of B , the government takes the land if $B \geq V(x)$, that is, if the land is more valuable in public use, given its current value to the owner. The resulting probability of a taking from the landowner’s perspective, prior to the choice of x , is now $1 - F(V(x))$, where $F(V(x))$ is the probability that $B \leq V(x)$, with $F' > 0$.

The expected social value of the land in this case is

$$\begin{aligned} & F(V(x))V(x) \\ & + [1 - F(V(x))]E[B|B \geq F(V(x))] \\ & = F(V(x))V(x) + \int_{V(x)}^{\infty} B dF(B) - x, \end{aligned} \quad (5)$$

and the first-order condition defining x^* is

$$F(V(x))V'(x) - 1 = 0, \quad (6)$$

which is the analog to Eq. 2 with $F(V(x)) = 1 - p$. The expected private value is

$$F(V(x))V(x) + [1 - F(V(x))]C(x) - x, \quad (7)$$

and the first-order condition defining the privately optimal level of investment is

$$\begin{aligned} & F(V(x))V'(x) + [1 - F(V(x))]C'(x) \\ & + F'(V(x))V'(x)[V(x) - C(x)] - 1 = 0. \end{aligned} \quad (8)$$

Note that $C' \equiv 0$ is no longer sufficient for efficiency, but it is still necessary. Now, in addition to being lump sum, compensation must also equal the value of the land at its efficient level of investment; that is, $C = V(x^*)$. The reason for this additional requirement is that landowners view the probability of a taking as depending on their

level of investment. In particular, by investing more (less), they can reduce (increase) that probability of a taking because it becomes less (more) likely that $B \geq V(x)$. Consequently, if compensation is less than full ($C < V(x)$), owners will overinvest to decrease the probability of a taking, and if compensation is more than full ($C > V(x)$), they will underinvest to increase that probability. Combining this with the lump-sum requirement yields $C = V(x^*)$ (Miceli 1991).

Hermalin (1995) shows that two other compensation rules will also achieve the efficient outcome in this context. The first requires the government to pay owners the full value of the land in public use, or $C = B$. In this case, landowners invest efficiently because they internalize the full social value of the land. Alternatively, compensation could be set at zero, but the landowner could be given the option to “buy back” the land in the event of a taking for a price equal to the realized value of the land in public use, B . The difference between these two rules depends on the assignment of property rights in the land when it potentially has public value. Under the first rule, the landowner holds the right, whereas under the second, society holds the right.

The preceding discussion assumed that the government behaved in a socially benevolent way in making its taking decision, but many have argued that an important reason for requiring compensation for takings is to prevent the government from converting too much land to public use (Johnson 1977). A government that considers the dollar costs of a taking as embodied in the compensation rule, rather than the true opportunity costs, is said to have “fiscal illusion” (BRS). To reflect this view of government behavior, suppose that once B is realized, a taking occurs if $B \geq C(x)$. It follows that “full” compensation will be necessary to prevent excessive takings, but simply setting $C(x) = V(x)$ will revive the moral hazard problem that initially gave rise to the BRS no-compensation result. One solution is the lump-sum rule, $C = V(x^*)$, which will simultaneously eliminate moral hazard by landowners (because compensation is lump sum) and induce only efficient takings by the government (because compensation is full).

Consider also the two rules proposed by Hermalin, both of which were shown above to induce efficient investment. Under the rule that sets $C = B$, the government will be indifferent between taking the land and not taking it for any realization of B . The landowner, however, will only want efficient takings to occur – that is, those for which $B \geq V(x)$. Thus, efficiency of the takings decision will depend on whether the government conforms to the wishes of the landowner. As for the buyback rule, since compensation is nominally set at zero, the government will initiate a taking for any $B > 0$, but the landowner will buy back the land whenever $V(x) \geq B$ or whenever a taking is not efficient. Thus, the outcome will be efficient.

A final compensation rule that balances the incentives of landowners and the government is the threshold rule proposed by Miceli and Segerson (1994). According to this rule, the government pays full compensation if it acts inefficiently to take (or regulate) the land, but it pays zero compensation if it acts efficiently. Formally, the rule is written as follows:

$$C = \begin{cases} V(x), & \text{if } B < V(x^*) \\ 0, & \text{if } B \geq V(x^*) \end{cases} \quad (9)$$

The efficiency of this rule is established as follows. Assume the landowner invested efficiently. Then, once B is realized, if $B \geq V(x^*)$, the taking is efficient and compensation is zero. Thus, a government with fiscal illusion will incur a net benefit of $B > 0$ and so will go ahead with the taking. In contrast, if $B < V(x^*)$, a taking is not efficient and compensation is full. Thus the government will incur a net loss of $B - V(x^*) < 0$ and so will refrain from the taking. In both cases, the government acts efficiently. Moving back to the land use decision, the landowner, who anticipates the government’s behavior, will choose x to maximize

$$F(V(x^*))V(x) - x, \quad (10)$$

which has x^* as its solution. The Nash equilibrium therefore involves efficient behavior by both the landowner and the government.

The noteworthy feature of the compensation rule in Eq. 9 is that, in an efficient equilibrium, no compensation is paid for takings. This is clearly contrary to legal practice in takings cases involving physical acquisitions where compensation is typically required, but, as will be discussed below, it is consistent with not paying compensation in regulatory takings cases.

A final class of takings models, referred to as “constitutional choice” models, views landowners as designing the compensation rule from behind a veil of ignorance regarding which parcels will be taken for public use. In this setting, all landowners are equally at risk of having their land taken, given that it is efficient to devote some land to public use, but landowners also know that any money paid to takings victims must be raised by taxes assessed on all landowners. Thus, rational individuals will presumably account for both sides of the public budget in designing the compensation rule and will therefore not be overly stingy (in case their land is taken) or overly generous (in case it is not).

The prototypical model of this sort is by Fischel and Shapiro (1989) (also see Nosal (2001)), which is identical to the BRS model except that the probability of a taking is written as $p = s/n$, where n is the total number of parcels in the jurisdiction and s is the number that will be randomly taken. The public benefit is written as $B(s)$, which will be enjoyed by all landowners (including those whose land is taken), where $B' > 0$, $B'' < 0$. Compensation is written as a fraction of property value, or $C = \alpha V(x)$, where α is a nonnegative constant, and per-person tax liability is also assessed as a fraction of property value, or $T = tV(x)$, where t is the tax rate. The resulting expected wealth of a landowner is

$$(1 - p)V(x) + pC + B(s) - T - x \\ = (1 - p + p\alpha - t)V(x) + B(s) - x. \quad (11)$$

The landowner chooses x to maximize this expression, taking p , s , α , and t as given. The resulting first-order condition is

$$(1 - p + p\alpha - t)V'(x) - 1 = 0. \quad (12)$$

As for the government, if it has fiscal illusion, it will choose s , the number of parcels to take, to maximize

$$nB(s) - sC. \quad (13)$$

The resulting first-order condition is

$$nB'(s) - C = 0. \quad (14)$$

Equations 12 and 14 jointly determine the optimal behavior of landowners and the government, given the compensation rule, as reflected by α , and the tax rate t . As noted, these parameters are determined by citizens from behind a veil of ignorance to maximize overall welfare, subject to a balanced budget condition. The latter is given by $sC = nT$ or

$$p\alpha V(x) = tV(x) \quad (15)$$

for any x . It follows that $p\alpha = t$, which immediately implies that $x = x^*$ in Eq. 12. Thus, landowners invest efficiently regardless of the value of α . Although both the compensation rule and the proportional property tax are potentially distortionary with respect to the choice of x , in the current model the two distortions exactly offset through the budget constraint, resulting in an efficient level of investment for any amount of compensation (Miceli 2008). Finally, substituting for C in Eq. 14 implies $nB'(s) - \alpha V(x^*) = 0$. If $\alpha = 1$, this becomes

$$nB'(s) = V(x^*), \quad (16)$$

which says that parcels should be taken until the aggregate benefit from the last parcel taken just equals the opportunity cost. This, of course, is the Samuelson condition for efficient provision of a pure public good. Thus, if compensation is full, the efficient level of the public good is provided. This, therefore, is the choice citizens would make in designing the optimal compensation rule.

Regulatory Takings

Much more pervasive than physical acquisitions are government regulations that reduce the value of land without seizing title to it. Examples include zoning, environmental and safety regulations, and historic landmark designations. As noted, many courts have granted the government broad police powers to enact such regulations in the public interest without requiring them to compensate landowners, but in some cases the regulation goes so far in reducing the value of the regulated land that courts have declared it to be a regulatory taking for which compensation is due. The question is where the dividing line should be between compensable and non-compensable regulations (Michelmann 1967; Fischel 1995b).

From an economic perspective, there is no substantive difference between a government action that seizes land for purposes of providing a public good and one that merely regulates that same property for purposes of preventing an external harm. In both cases, the government imposes costs on some landowners in order to confer benefits on others. The only difference is the extent of the taking. This point is clear in the context of the above models, which apply equally to full or partial takings. From a legal perspective, however, the two types of cases are often treated very differently by courts – as noted, full takings typically require payment of compensation, whereas partial takings do not. This dichotomy poses a significant challenge for developing a positive economic theory of the compensation question.

One answer is provided by the threshold compensation rule in Eq. 9, which, recall, only requires compensation to be paid for government actions that are inefficiently imposed. In this sense, the rule resembles the famous test for compensation announced by the US Supreme Court in the landmark case of *Pennsylvania Coal v. Mahon* (260 U.S. 393, 1922). According to this rule, referred to as the “diminution of value” test, compensation is only due if a regulation “goes too far” in reducing the landowner’s value, where, in light of Eq. 9, “too far” can be interpreted as

“inefficient.” The efficiency of the Nash equilibrium under this rule, as demonstrated above, implies that compensation will be rarely paid, which is consistent with legal practice in many regulatory takings cases.

Another perspective on the distinction between full and partial takings as regards compensation is Epstein’s idea, discussed above, that compensation need not always be monetary – it can also be in kind. Regulations that are enacted for the purpose of preventing externalities impose costs on individual landowners by limiting those things they can do with their property, but they also confer reciprocal benefits that serve as in-kind benefits. If the regulation is efficient, the benefits exceed the costs on average, which justifies non-payment of monetary compensation. In contrast, physical takings are more likely to “single out” a small number of landowners to bear costs for the benefit of many, as when land is taken from a few to provide a public good. Since in-kind compensation is not generally available to these takings victims, monetary compensation is necessary to satisfy a just compensation requirement.

Tax Amnesty

Carla Marchese

Dipartimento di Giurisprudenza e Scienze Politiche, Economiche e Sociali, POLIS Institute, Università degli Studi del Piemonte Orientale “Amedeo Avogadro”, Alessandria, Italy

Definition

Tax amnesty is the opportunity given to taxpayers to write off an existing tax liability (including interests and fines) by paying a defined amount. Such offers are usually presented as being exceptional and available for only a limited period of time. Amnesties can either be general or restricted to certain groups of taxpayers or taxes, and they routinely include the waiving of criminal and civil penalties.

Prevalence and Types of Tax Amnesties

Both local and central authorities grant tax amnesties. Over the past 50 years, the central governments of some developing countries (e.g., Argentina, Colombia, Brazil, India, the Philippines, Turkey) have repeatedly offered amnesties (Le Borge and Baer 2008), as have the central governments of developed countries plagued by specific economic problems such as recession, financial crisis, and large public debt (e.g., Ireland, Italy, Spain, Greece, Portugal). Many developing and developed countries have also occasionally resorted to some form of amnesty to foster flight capital repatriation or to ease economic liberalization and openness to international trade. Local governments, too, often resort to tax amnesties. Many US states have made repeated use of waves of amnesties (Alm and Beck 1993; Mikesell et al. 2012) in response to a variety of motivations, including decreased central support for local tax enforcement in the 1980s (Dubin et al. 1982) or the dwindling of local tax revenue coupled with a mandatory balanced budget in the 2000s.

Lawmakers and local administrators are constantly devising new types of tax amnesties. Innovation and differentiation in this field is likely sparked by the need to capture the attention of the public and, where tax amnesties are frequent, to appeal to groups that have not yet been reached by previous offers.

In terms of the immediate financial benefits to participants, some tax amnesties not only reduce or waive sanctions and interest but also reduce the principal on the tax. These are the so-called extensive tax amnesties (Franzoni 1996; Macho-Stadler et al. 1999), which also often provide immunity from audits for past, and sometimes future, tax liabilities.

The timing of amnesties is a key feature in their functioning: how long the program is available, whether or not extensions will be granted, and the frequency with which amnesties are offered clearly affect their results (Mikesell 1986). In many countries, unaudited taxpayers who spontaneously report tax evasion can be granted a standing permanent tax amnesty (Andreoni 1991), although these amnesties are never of the extensive type and are sometimes available only for a limited time after the violation. Standard tax amnesties instead can be designed to cover recent or past liabilities that still fall within the expiration term of the tax obligation. The benefits of amnesties for the participants sometimes also extend to the future, as various provisions can be introduced to reduce expected future liabilities. For example, in some amnesties, participants who increased their subsequent reported income by a given percentage for several years were exempted from future audits on those years, barring major violations. Portugal granted an amnesty of this type in 1986 (Baer and Le Borgne 2008, p. 10).

Another important aspect of tax amnesties is the information disclosed by participants, which serves to condition their future expected payments. Some amnesties even provide for the free writing-off of past liabilities, so long as the taxpayer's latest tax return was honest (Pommerehne and Zweifel 1991). When a new tax return is filed, the tax administration ordinarily maintains its full powers of auditing. Taxpayers participating in an amnesty may also be subject to special

surveillance in subsequent years. Of course, these policies reduce the amnesty's appeal and its potential as an immediate revenue source. If the government is primarily interested in raising revenue and encouraging participation to boost the immediate amnesty's proceeds, the auditing powers can be limited or excluded, and anonymity can be offered to the amnesty participants. One way this can be achieved is by allowing participants to disclose their liabilities and to make the amnesty payments to a third party (such as a bank), which releases a certificate to be used as a shield in case of future tax audits: the 2001 Italian tax amnesty for capital repatriation with these characteristics was called a "scudo fiscale" (tax shield). However, it is also true that the government's commitment not to access such information may be more or less credible. In Italy, a 2011 law introduced a new tax on capital that benefited from that 2001 amnesty. The new tax was justified on the basis of the benefit principle, with the benefit being continued secrecy to those who entered the amnesty despite newly introduced legislation granting the tax administration easier access to taxpayers' bank accounts.

In terms of the extent of coverage, amnesties are often granted only to taxpayers not yet under investigation. These could be taxpayers who missed a filing deadline (e.g., for VAT), or who failed to file one or more tax returns, or simply those who reported regularly but cheated. However, amnesties can also include those whose liability has already been assessed or liquidated (i.e., the so-called accounts receivable). By granting an amnesty, the tax administration surrenders the right to collect payments from taxpayers through standard means, such as audits, injunctions, or litigation in courts. The ensuing opportunity cost is likely to be larger if the ordinary collection process has already been initiated, as in the case of accounts receivable. Another aspect of coverage is the type of tax or tax base to which the amnesty refers. From this point of view, in principle, all types of payments can be considered, including social contributions, charges and fees, and so on. Amnesties tend to be general to assuage taxpayer fears that further audits will ensue if one specific hidden tax base is disclosed. With

reference to the tax base, it is also important to distinguish standard amnesties from those specifically targeted to flight capital, since the latter involve problems of international relations and tax competition. Amnesties can also involve leverage, so in some cases participants have been required to invest the hidden tax base in special public debt bonds. These securities delivered no yield or a low yield and could not be traded before a given date. As in the case of intermediation by third parties, these special bonds could be used as a shield in case of tax audits. An amnesty of this type was granted in Spain in 1991 (Macho-Stadler et al. 1999). In other cases (e.g., the 1987 amnesty in Argentina) the evaded tax base could also be invested in private enterprises, provided that the investment was twice the evaded tax base amount.

Amnesties are also characterized by the interventions supporting them, which range from global reforms of the tax system to specific provisions aimed at strengthening tax enforcement. The underlying reasoning is some stick should be given along with the carrot represented by the amnesty, in order to avoid negative effects on compliance. These further interventions often include harsher penalties for tax evasion, reorganization of the activities and of the legal capabilities of tax auditors, modifications of laws regulating tax shelters, and use of the funds collected through the amnesty for financing enforcement activities. Moreover, specific information can be sent to the perspective participants to inform them of their likely tax liability, together with the threat of naming and shaming evaders who do not participate or of increasing penalties specifically for them.

A traditional justification often provided for granting a tax amnesty is that special circumstances may motivate unwanted breaches of the law or mistakes by citizens. This is mainly true for amnesties that accompany huge reforms in taxation or other related fields or that are granted after major upheavals such as political regime change, changes in currency, and so on. In these cases, the amnesty is well grounded in terms of equity and should not be harmful in terms of efficiency, since it should be unexpected (and will not induce an ex ante evasion

increase) and unlikely to be repeated (and will not encourage subsequent evasion). The resort to tax amnesties, however, is more frequent and widespread than one would expect on the basis of exceptional circumstances alone. The Philippine government, for example, called its 1980 amnesty the “final amnesty,” although many others followed.

Amnesties are actually a well-established, ancient, and widely used institution. There is evidence of a tax amnesty in the Rosetta stone (from around 200 B.C.): the priests of a Memphis temple thank the Monarch for not demanding a large sum of tax arrears due by the people. Tax amnesties can also be considered a form of pardon that shares some features with other past or recent institutions (Cassone and Marchese 1999) in the field of religion (jubilees, indulgences), criminal justice (plea bargaining), and penal or civil violations (amnesties for illegal immigration, breach of regulatory rules, and so on). The provision of statutes of limitation for some legal obligations and even for crimes can also be considered as a limiting case of a permanent standing amnesty, which might be rationalized on the basis of the fact that as time passes without any actual law enforcement, the net advantages of delayed enforcement tend to vanish or even turn to disadvantages. These considerations suggest that amnesties might exert some positive social function. However, since tax amnesties are also harshly criticized, it is important to understand both the pros and the cons of this institution.

Pros

Among the pros is the idea that amnesties encourage repentance of violators and/or foster their willingness to behave cooperatively in the future (Malik and Schwab 1991). People may be unable to clearly assess ex ante the costs and benefits of violating rules, such as engaging in tax evasion, and while ex post repentance may ensue, the fear of heavy sanctions for past conduct sometimes discourages disclosure of the violation. Amnesties have the positive effect of rendering repentance less costly and the return to honest behavior (such

as the regular payment of future taxes) therefore more likely. The benefits of amnesties in this case are the partial restoration received by society (through payments or other forms of contribution by the violators) and by expected improvement in future compliance.

While repentance implies some form of limited rationality, the full rationality of taxpayers can also be assumed when justifying the participation of citizens and the granting of tax amnesties by governments. Participation can be justified if it is in the best interest of the taxpayer to revise her economic calculus because the costs of evasion have increased, as a result of actual or anticipated changes in law enforcement, for example, which increase the expected sanctions for past misconduct. These revisions, however, are more likely for small evaders that can easily adapt to even marginal changes in the law, while the effects on repeat evaders who have hidden large sums are probably limited.

Good economic news might also provide the motivation for granting an amnesty. If the economy is growing quickly thanks to policies of liberalization and of opening to international trade, it may be the case that firms can benefit more in the new environment if they are legal and have a clean tax record, as this paves the way for accessing the credit market or for listing on the stock exchange and so on. For a firm that has been operating for some time in the hidden economy, however, shifting to legality could imply a huge cost in terms of sanctions for past evasion, and an amnesty can grease the wheels of change. The results of the amnesty in this case should be evaluated not only with reference to the effects on tax revenue but also in terms of the effects on GDP that should ensue thanks to productivity increases in firms that were able to shift to legality (Bose and Jetter 2012).

Amnesties can improve efficiency when they are designed as an optimal discriminatory policy in the field of taxation (Marchese and Cassone 2000). Amnesties are in general discriminatory since they imply a more favorable treatment for those who evaded tax – and for those who can regularize their position at a discount – than for those who complied from the outset on the one

hand or for those who were discovered and punished before the amnesty on the other. Amnesties can perform a role similar to that of price discrimination which can increase a firm's profits. For example, selling a good in different markets at different prices can boost a firm's revenue, and this might occur even if some arbitrage arises; in other words, for example, even if a few of those who were expected to buy at a higher price manage to buy at a lower one. Amnesties can be seen as a way of opening another market beyond that of compliance. If such an offer appeals to a large enough number of new "customers", government revenue can increase even if the number of regular tax compliers decreases somewhat. Price discrimination, however, can be optimally designed only if there are characteristics that distinguish markets or, in our case, that distinguish perspective evaders and compliers.

For a case in which an efficient discrimination can be applied, consider economic shocks that affect particularly some firms or individuals (e.g., sectorial crises, adverse life events, and so forth). Tax evasion can work as an extreme method of increasing disposable income in such circumstances. Those more likely to be harshly hit by a negative shock are also those more likely to resort to such extreme measures. In this case, an amnesty helps the unluckiest to improve their circumstances as well as easing their return to legal behavior. Since there might always be a share of the population experiencing these problems, a standing permanent tax amnesty can be justified both in terms of efficiency (supplying insurance) and of equity (helping those more in need) (Andreoni 1991).

Another possible efficiency-based rationale for resorting to amnesties as a discriminatory policy is related to the exploitation of differences in the visibility of tax evasion (Marchese and Cassone 2000). Citizens who are more confident about their ability to remain undetected are less likely to file their tax returns regularly, but they may still be willing to pay to eliminate the risk of evading the law and thus be interested in an amnesty. While it might be difficult to distinguish *ex ante* those who are more difficult to tax, it should become clear *ex post*, since the more visible should comply immediately, while the less visible

dare to wait. If a favorable amnesty is offered, the latter can enter it. The tax administration bears an opportunity cost since without the amnesty it might have enforced sanctions on the evaders, but if the payment asked for entering the amnesty equals the expected sanctions plus a risk premium, the result could be positive in terms of government revenue. Note that this approach can justify expected, repeated, and periodic tax amnesties, which should work like a form of sales (Cassone and Marchese 1995). Sales, too, aim at discriminating among customers according to their impatience. It is well known that efficient periodic sales can be compatible with a market in equilibrium, in which the share of customers buying in periods in which the full price is applied is stable and the total revenue is larger than if sales are not held. Similarly efficient periodic tax amnesties are compatible with the stability of the number of regular compliers. A characteristic of both efficient amnesties and sales is the greater exploitation of those with the lowest demand (those who buy during sales or those who participate in a tax amnesty), while a better deal should be offered to regular buyers or compliers. This might seem somewhat counterintuitive, but the idea is that those who buy during sales and those who participate in amnesties, while paying less in absolute terms, should be fully expropriated of their willingness to pay, while those characterized by high demand (regular buyers and compliers) should be left with some net gain.

When amnesties are offered to tax evaders already under investigation, they can be rationalized as a form of plea bargaining. In other words, the tax administration uses the amnesty to profitably renounce part of the expected proceeds as long as this also involves a partial cashing of its credits and a substantial reduction in the implementation costs it would have borne. As in the case of plea bargaining, it is expected that those who are more willing to participate in the amnesty are also those who more patently violated the law, since they would lose if they tried to contest their liability. It is widely held that plea bargaining can be considered as an efficient selection tool, as on the one hand the guilty, who risk more, should reveal themselves by pleading guilty and thus be

properly sanctioned, while by not pleading guilty, the innocent should go on to trial, where they are likely to be acquitted (Grossman and Katz 1983). A similar type selection is possible through amnesties. However, some problems may ensue with tax evasion, as long as only monetary sanctions are foreseen. In this case, *ceteris paribus*, the amnesty is more appealing to those who have enough wealth to bear the liability and are thus easier to reach through standard means of enforcement. An amnesty, instead, is not relevant for those who are sanction-proof, as they have nothing to lose if an audit occurs.

While efficient discrimination is a potential, overall justification for tax amnesties in both developed and developing countries, in the latter countries, a further motivation is that they can help compensate for organizational problems related to performing audits and dealing with taxpayers' tax-related appeals. Here, the main idea is that, whenever the productive capacity of the tax administration is modest and fixed in the short run, performance can be improved by using the amnesty to deal with the oldest unsolved cases, in order to concentrate resources on the most recent and probably more visible and thus easier to resolve ones. Moreover, amnesties can also be used by governments to periodically curtail the rents extracted from evaders by corrupted auditors seeking bribes. As long as the amnesty provides a large enough discount, taxpayers will prefer to settle their liabilities directly with the state.

Cons

On the efficiency grounds, the main argument against tax amnesties is that credibility problems may arise concerning the ability and/or commitment of the state to enforcing the tax law (Stella 1991). The idea is that governments in general, when granting an amnesty, try to look tough for the future, in order to induce compliance. Citizens, however, base their beliefs on past experience. Even if amnesties are accompanied by declarations about new stronger enforcement efforts, taxpayers, who take past auditing policy into account, are likely to only slightly correct

their perception of the riskiness of tax evasion. Hence, the collection of resources from past evaders is likely to be low, and the expectation of future amnesties can induce previous compliers to evade. If an amnesty leads to larger evasion, a further subsequent amnesty might appear even more justified, but this might lead to a slippery slope, in which more and more generous and frequent amnesties are granted. Amnesties, in sum, could reveal the weakness behind the feigned tough stance of a government, thus permanently endangering its taxing capacity, i.e., reducing the overall taxpayers' willingness to pay, either through regular compliance or in amnesties.

As long as a government lacks the commitment to enforce the tax law, the aforementioned discriminatory function of amnesties would actually be impossible to implement due to the lack of credibility of the threat of punishment. Discriminatory policies have also been criticized because the tax administration might lack enough information to design them, if taxpayers' attitudes differ along many dimensions (such as income, age, sex, location, and so on). It might even be technically impossible to devise a sufficiently fine-grained discriminatory mechanism.

A further problem raised by amnesties is that they are costly, and their costs are difficult to anticipate and to correctly evaluate (Baer and Le Borgne 2008). As already seen, a large share of these costs is represented by the opportunity costs of renouncing pursuit of the standard enforcement activity over the participants, thus renouncing the revenue that they would otherwise have produced. When the amnesty foresees payment by installment, some installments may be missed, and the initial assessment of the amnesty's proceeds proves incorrect. Other costs can be due to a temporary suspension of enforcement activities, which is often granted during the period in which the amnesty is pending. Moreover, amnesties need to be well designed and advertised: "Get to us before we get to you" is the famous slogan used to advertise the Michigan 2002 tax amnesty. Interventions can include mass mailings of information to prospective participants, the provision of an information hotline, and so forth. Last but not

least, if amnesties endanger the future compliance of honest taxpayers, this prospective revenue loss also needs to be accounted for. Difficulty in evaluating the total costs involved in an amnesty may actually contribute to their popularity, as they would thus be based on a kind of fiscal illusion.

In terms of equity, most critics are of the view that amnesties are unacceptable because they introduce discriminatory treatment of citizens according to law enforcement. More specifically, when an amnesty is granted *ceteris paribus*, the participants can fulfill their tax obligations by paying different amounts than those who complied from the outset or from those who were caught in the meantime. On the other hand, if one focuses not on the equity of rules but on the social outcome instead, one sees that even without amnesties, honest taxpayers and tax evaders routinely end up with differences in their actual contributions to the financing of the public budget. Moreover, as long as the amnesty collects revenue from tax evaders, these differences are reduced, thus securing more horizontal equity. Even vertical equity could increase, if the rich evade more and take advantage of tax amnesties more often. Here too, as is generally acknowledged, focusing on justice in procedures or on justice in outcomes leads to different conclusions.

Even by considering amnesties as discriminatory in principle, the economic approach would suggest considering the potential equity efficiency trade-off resulting from possible compensation for those who are negatively hit thanks to the proceeds that an efficient amnesty should produce. However, the compensation principle is problematic and a source of widespread debate: it would either have to involve the actual payment of compensations (and this would be difficult to plan for and is therefore practically never done) or a comparison on paper of utility gains and losses, which is not acceptable to those who claim there is no objective unit of measurement for making these calculations. At any rate, some types of amnesties, such as those aimed at capital repatriation or at easing the opening of the economy to international trade, have clear-cut and widely recognized general economic benefits extending beyond the effects on tax revenue. They are

therefore often considered more acceptable from an equity point of view.

Another criticism of amnesties is that external incentives might endanger internal incentives to legal behavior. In other words, as long as tax compliance in modern societies largely rests on the internal incentive represented by a moral imperative, the introduction of external incentives based on the gains that an amnesty can produce for both those who participate and those who do not could push the public reasoning away from the moral perspective. This might have negative effects on compliance, since in many cases, pure economic calculus shows that tax evasion pays, so widespread evasion should be expected. Amnesties, however, are generally considered as acceptable on the grounds of equity if they discriminate in favor of more deserving people: amnesties that work as a form of insurance for the most unfortunate or exceptional amnesties granted to citizens faced with the difficulties posed by large-scale overhauls of the tax code or other major changes.

Not everyone who files for an amnesty is a tax evader. Even honest taxpayers may fear having made mistakes on their tax returns and want to avoid being audited or going to court or they may also wish to avoid the inconvenience and cost of being audited. Particularly in developing countries, where enforcement is often intrusive and burdensome for citizens, amnesties can appeal to honest taxpayers. The role of amnesties in this case is ambiguous. On the one hand, they produce a benefit for participants who are honest and deserving from a social point of view; but, on the other, they can imply perverse incentives for the tax administration (Franzoni 2000) to capitalize on its own malfunctioning.

The Observed Effects of Amnesties

As for participation, amnesties tend to deliver somewhat extreme results. Either the entire potential population participates or only a very few members do. This is due to the fact that amnesties ordinarily reduce the perspective workload of auditors, who no longer need to focus on those who entered the amnesty and can thus target

nonparticipants more. Hence, the risks for non-participants (and thus their motivation for taking part) increase with the number of those who have already applied. In a certain sense, there is a network effect, and even in successful amnesties, participation tends to accelerate toward the end of the period of validity, as people wait and see how large participation has been. It is thus suggested that the period in which an amnesty is pending should not be too long (around 90 days), in order to avoid wasting time and to reduce costs. Moreover, this period should not coincide with that in which tax reports are filled-in, since it has been shown that this might exacerbate the trade-off that might arise between reporting for the amnesty and reporting for paying taxes of the current year (Alm and Beck 1990). If both reports have to be made at the same time, when confronted with two ways for reducing their risk in the field of taxation, past evaders can more easily assess the relative advantages. If the amnesty is very cheap, they might even reduce the overall amount they pay, with a negative result for the public budget.

The economic effects of amnesties can be estimated using econometric techniques. The reliability of the results is limited by the fact that one either studies a specific amnesty – but then the data collection should be very detailed, and the results might at any rate not have general significance – or one can pool many amnesties, but then one needs to control for the specificities of each case considered. Moreover, it is not easy to disentangle the specific effects of amnesties from those of the supporting programs often jointly enacted.

Many studies have focused on the large number of amnesties granted in the USA, which present the advantage of providing a large data set of cases sharing a common legal and economic background. Mikesell and Ross 2012 arrive at a total of 117 amnesties granted by 41 States in the period 1980–2011. The results of these econometric studies show that some features of amnesties are decisive for boosting the proceeds, such as the effort made in advertising, the inclusion of accounts receivable, and the possibility for installment payments. Other relevant variables are those

linked to tax evasion opportunities, either in terms of self-employment or with reference to less auditing in the state by the central government. While the amnesties granted in the 1980s also included cases where eligibility was very restricted, the most recent amnesties are more often characterized by large admission criteria. Moreover, recent amnesties tend to waive interest to a larger extent (whereas the principal is never reduced) and are less often accompanied by supportive measures aimed at reinforcing future compliance. This might also be due to the repetition of amnesties over time, a fact that tends to reduce the number of new enforcement interventions not yet enacted that can be introduced and to undermine the credibility of further threats, so that they are mainly dispensed with. From the point of view of gross revenue collected, US states tax amnesties were sometimes successful (with an impact at any rate always below 3% of the yearly tax revenue), while their long-term effect is unclear and probably nil or negative (Alm and Beck 1993; Luitel and Sobel 2007). It has been noted that the participants totally unknown to the tax administration mainly continued to report after they entered an amnesty, but their contribution to the tax revenue has often been scant (Christian et al. 2002), thus raising some questions about the role of amnesties in significantly enlarging the future tax base. The average sums paid in amnesties were often small and related to recent years. Since there is no reason to expect this on an objective basis, the explanation may either be a lack-of-recall of past evasion or a rational calculus about the fact that evasion made far in the past and not yet discovered is even less likely to be found out in the future. In general, there seems to have been some change over time in the goals that the states pursued by granting an amnesty, which mainly ranged from boosting future compliance to providing an immediate source of revenue.

For countries that often granted tax amnesties (including Italy, Ireland, India, the Philippines, and Turkey), the best results seem to have been reached whenever an amnesty was offered together with a policy aimed at strengthening enforcement capacity and at improving the overall efficiency of the tax collection system (Baer and

Le Borgne 2008). In some cases, instead, such as in Argentina, where measures of this type were not introduced, amnesties gave rise to a spiral in which forgiveness for not paying what was due according to a previous tax amnesty was also offered and participation in amnesties faded out over time. When a negative spiral is avoided, amnesties mainly modify somewhat the intertemporal profile of tax revenue; that is, they imply a temporary increase, also due to the fact that they anticipate the cashing in of some future revenue that would have been obtained through ordinary enforcement activity, followed by a subsequent decrease, with no change in the revenue trend.

Experiments have also been used to assess the effects of tax amnesties (Alm et al. 1990). It turns out that amnesties actually do foster subsequent increases in evasion. However, combining amnesties for the past with harsher penalties for the future prompts greater compliance. This combination is reminiscent of a feature that has also been deemed necessary for the efficient and equitable functioning of plea bargaining, where it is found that the judge should use discretionary power to threaten harsher penalties, so that those who plead guilty, while obtaining a discount compared to the new level of penalty, are actually given the sanction due (Grossman and Katz 1983).

Amnesties as a Public Choice Issue

Amnesties imply a kind of temporary modification of the social contract between citizens and the state on taxation. As with contract renegotiations, such modifications can be justified by the arrival of new information not available when the pact was signed or by changes in the preferences and objectives of the parties involved. It might, however, also arise out of intertemporal inconsistency, whenever the parties find it in their interest to renege on their past promises. In the specific case of taxation, the former case would occur with efficient amnesties that ease the adjustment to major changes or perform discriminatory tasks, while the latter would correspond to cases in which governments risk their credibility as law

enforcers in order to secure an immediate increase in revenue. The short-run perspective that often plagues the functioning of democratic governments can easily lead to intertemporal inconsistency. Notwithstanding the long-term benefits of tough tax enforcement, politicians who stay in power for a limited period are likely to be tempted by amnesties that grant immediately available proceeds, while they might not be so worried about the damage that will materialize only in the long run, after they step down. To avoid these drawbacks, in some countries, amnesties can only be introduced with the approval of large parliamentary majorities (as in Italy for amnesties waiving criminal offenses) or they are subjected to approval by referendum (as in Switzerland).

Amnesties can be tempting from the political perspective, too, because they represent means of gaining a quick increase in revenue without burdening the entire tax-paying population with changes in the tax law and rate increases. This might be particularly welcome in preelection periods, as politicians are keen on spending to boost economic growth and consent (the so-called political business cycle). Amnesties, however, might also be seen as a way of squeezing taxpayers, besides offending regular compliers. In fact, from the point of view of political consent, amnesties have not performed well. The US state governors granting one during the electoral year proved more likely not to be reelected (Le Borgne 2006).

Amnesties are relevant for politicians also when they participate in one. If information leaks and reaches the press, it can damage the social reputation and the possible political career of participants. Companies also risk damaging their reputation if it is discovered that they took advantage of an amnesty.

Economic psychology has characterized the implicit psychological contract between the state and the citizens concerning taxation. While citizens are obliged to pay taxes, the state must treat them respectfully yet punish those who fail to comply. If it does not punish them, the citizens who did comply may feel betrayed. In fact, in experiments where there are collective gains from cooperation, the participants often demand punishment for violators. In many cases, it turns

out that those who cooperated are ready to sacrifice a share of their gains in exchange for implementing the punishment. If amnesties are perceived as a breach of the psychological contract of taxation, they will encourage further tax evasion. However, it is also true that honest taxpayers might consider participants in an amnesty as willing to change their behavior. Frustration that some evaders may go unpunished in amnesties can also be dealt with if the hidden evaders are threatened with harsher penalties. In fact, punishment can serve two main purposes: retribution for illicit conduct and restoration of legal order. While the retribution recouped via amnesties is lower than that provided for by standard rules, amnesties can convey some advantages in terms of restoration as long as they foster greater future compliance. From this point of view, amnesties should be favored by those who are more generally in favor of alternative penalties aimed at facilitating the social rehabilitation of those who breached the law (Rechberger et al. 2010). The ambiguous role that amnesties can play implies that public debate over an amnesty program may have important consequences. This is confirmed by experiments in Switzerland and in Costa Rica conducted by Torgler and Schaltegger in 2005. They found that only amnesties approved by referendum lead to increased compliance. This effect can be traced back to the formation of public opinion through the public discussions among participants in the experiment that accompanied the referendum. Participants perceived the amnesty not as an imposition from above but as an agreed-upon intervention with useful functions, and this in turn increased the social pressure for cooperation.

As for public opinion on amnesties, the Bank of Italy (Cannari and D'Alessio 2007) conducted interviews in 1992 and 2004 in which questions were asked about the government motivations for granting an amnesty, the results expected, and the respondent's evaluation of such a policy. Regarding the first question, the majority of respondents think that the Italian state resorts to amnesties either because it is powerless to punish evaders or because groups of evaders had lobbied for preferential treatment. Yet in reference to the evaluation of the consequences and the moral

judgment of this policy, only about 30% of respondents have clear-cut negative feelings (that evasion will increase and the policy offends honest citizens), while the remaining respondents express more nuanced opinions. The negative feelings, however, were more frequent in 2004 than in 1992, possibly due to some deterioration of the government's credibility in light of repeated tax amnesties.

Besides being relevant for internal political affairs, amnesties can also be linked to the state of cooperation or competition between governments or levels of government, since they represent a means of dealing with externalities in taxation and in enforcement policies. It is also the case that forms of imitation or competition often arise among neighboring countries, so amnesties sometimes spread from one country to another. The importance of externalities in this field is confirmed by an empirical analysis of the motivations leading states in the USA to grant an amnesty, which revealed that the likelihood of amnesties increased as the effort of the federal government in auditing taxpayers within the state decreased (Dubin et al. 1982; Le Borgne 2006). In the field of international relations, in 2010, the OECD suggested offshore voluntary disclosure programs as a solution to help governments benefit quickly in terms of revenue from the effects of improvements in international cooperation for information exchange and transparency that have occurred since the onset of the financial crisis. Voluntary disclosure implies a "limited-time offer by the government to a specified group of taxpayers to settle undisclosed or unpaid tax liabilities for a previous period in return for defined concessions over civil or criminal penalties. In some cases, there are also concessions over the amount of tax and/or interest payable" (OECD 2010, p. 11): the definition is very close to that of an amnesty.

International organizations such as the IMF have studied more in general the policy of tax amnesties (Baer and Le Borgne 2008). They arrive at a substantially negative evaluation of this institution. Their suggestion in this field is to avoid the resort to amnesties, while pursuing alternative policies instead, such as: (i) trying to reduce tax evasion by addressing its basic determinants (unsustainable

tax system, insufficient and improper enforcement, the malfunctioning of courts, etc.); (ii) resorting to permanent programs for encouraging disclosure of tax evasion and for granting extended payment agreements to taxpayers under economic stress for personal or conjunctural reasons; and (iii) improving the functioning of the tax administration, for example, by granting it with the power of disposing of cases unlikely to lead to net contributions to the revenue. The basic idea is to consolidate taxpayers' expectations about the commitment of the state to fighting tax evasion, while also dealing with the problems that often motivate the granting of an amnesty in other ways. These policy suggestions have sound economic foundations. They can be likened to the commercial practice that uses price discrimination systematically rather than intermittently, so that, for example, special sales can be replaced by permanent offers at outlets specializing in major discounts. Following these suggestions, however, is not easy, particularly when one considers developing countries and countries where corruption is frequent. Whenever interventions such as a standing amnesty are introduced, it is possible that corrupt auditors will accept bribes in order to say that a taxpayer voluntarily disclosed her evasion. Problems of this type have arisen in the past even in the USA (Andreoni 1991). Likewise, whenever a personalized deal (such as an individual installment plan for tax payments) must be designed, the risk of corruption of officials tends to be greater than when general public interventions such as tax amnesties are implemented, given that they are often regulated by the law. These considerations, coupled with the existence of genuine unanticipated phenomena that cannot be dealt with efficiently through other means or with discrimination opportunities not available elsewhere, suggest that amnesties are and are likely to remain an accepted tool in tax administration.

Tax Evasion by Firms

Laszlo Goerke

IAAEU (Institute for Labour Law and Industrial Relations in the European Union),

University Trier, Trier, Germany

Abstract

A standard finding in the analysis of tax evasion and avoidance by firms is that the decision about the firm's activity level can be separated from the evasion choice and vice versa, irrespective of the tax under consideration. The implications, relevant empirical evidence, and the robustness of this separability feature are surveyed. The article finishes with speculations about topics of future research with regard to tax evasion or avoidance by businesses.

JEL-Classification: H 25, H 26, K 34

Definition

Tax evasion (avoidance) by a firm represents the attempt to illegally (legally) reduce the payment of taxes which have to be remitted by a profit-maximizing entity to below the level prescribed by law.

Introduction

A substantial fraction of tax revenues in OECD countries is remitted by firms (OECD 2013). This is the case either because firms are legally obliged to pay, for example, corporate income, payroll, property, or consumption taxes, or because firms act as withholding agents, inter alia with respect to personal income taxes and social security contributions. Therefore, firms and businesses have ample scope for tax avoidance and tax evasion

activities. Slemrod (2007, p. 28), for example, reports that the average tax gap in the United States – that is, the difference between the amount of taxes due and the amount paid voluntarily and in time – was about 16% in 2001. Moreover, the tax gap for income taxes of small corporations and for business income was substantially higher. As a further piece of evidence, the VAT compliance gap is estimated to exceed 10% in a number of European Union member states (Keen 2013). Consequently, tax evasion and avoidance by firms is not only feasible but also seems to be widespread.

Despite this evidence, the vast majority of contributions on tax evasion has focused on and analyzed the decision by individuals to evade income taxes. (The relevant literature is surveyed, for example, by Andreoni et al. (1998), Alm (1999), Slemrod and Yitzhaki (2002), Marchese (2004), Franzoni (2009), and Sandmo (2012). The contributions by Cowell (2004) and Slemrod (2007) also include substantial sections on firms. See also ► “Tax Evasion by Individuals”, this encyclopedia.) The extant literature on tax evasion by firms has then focused on results which are specific to these entities. Such features which differentiate a firm from an individual are, inter alia, (1) all payoffs can be defined in terms of money; (2) firms often have market power; (3) risk neutrality may be an appropriate approximation of preferences; and (4) within a firm, conflicts of interest between owners and managers are likely to arise.

Basic Model

Subsequently, we take up some of these features and analyze a firm’s tax evasion and avoidance behavior. We consider a single firm which maximizes expected profits. In order to do so, the firm determines the level, x , of economic activity and the extent of tax evasion or avoidance. The overall rate of all taxes the firm has to remit is labeled t . If the firm does not evade or avoid taxes, its (legitimate) profits are given by $\pi(x, t)$. We assume that a profit-maximizing level of activity, x^* , exists. This activity choice, x^* , is defined by

$\pi_x(x^*, t) = 0$ and $\pi_{xx}(x^*, t) < 0$, where subscripts denote partial derivatives. Taxes remitted by firms will generally reduce profits, implying that $\pi_t < 0$ holds. This will be the case unless firms (1) can fully shift taxes forward to customers or backward to employees or suppliers of input goods or (2) act as withholding agents. In such a situation, $\pi_t = 0$ will apply. Furthermore, a pure profit tax will generally not affect a firm’s optimal activity choice ($\pi_{xt} = 0$). In general, however, higher taxes will reduce the incentives to exert an economic activity. This implies that the gain from higher activity shrinks with the tax rate ($\pi_{xt} < 0$).

If the firm avoids or evades taxes, it decides about the under-declaration of taxes, which is labeled E , such that the resulting monetary gain amounts to Et . We subsequently assume that taxes are under-declared ($E > 0$) and that E is less than the tax base, in contrast, for example to Virmani (1989) and Cremer and Gahvari (1992), who analyze models of tax evasion by firms which allow for corner solutions, i.e., outcomes in which either no tax evasion takes place or no taxes are paid. To ensure an interior solution, evasion or avoidance has to be costly. These costs are given by $C(E, t, F)$, where C is increasing in the under-declaration, E , for $E > 0$ at an increasing rate ($C_E(0) = 0 < C_E(E > 0)$, $C_{EE} > 0$) and also rising in the tax rate, t ($C_t > 0$), and a parameter F , which can capture the penalty which a tax-evading firm has to pay if evasion is detected ($C_F > 0$).

In the case of tax avoidance, profits may be considered as certain with regard to the outcome of tax payments. If tax evasion takes place, there is a probability, p , that evasion is successful and profits amount to $\pi(x, t) + Et$ and a converse probability $1 - p$ that the firm is audited and evasion is detected, so that profits are given by $\pi(x, t) + Et - C(E, t, F)$. If the firm evades taxes, expected nonlegal profits hence equal

$$\pi^N(x, E) = \pi(x, t) + Et - (1 - p)C(E, t, F). \quad (1)$$

The maximization of nonlegal profits π^N implies two first-order conditions:

$$\pi_x = 0 \quad (2a)$$

and

$$t - (1 - p)C_E = 0. \quad (2b)$$

The optimal activity choice, x^* , maximizes legal profits, π , while the optimal under-declaration, E^* , balances the marginal gain in terms of lower tax payments with the greater expected costs of evasion or avoidance.

Major Findings

From conditions (2a) and (2b), a number of fundamental insights can be derived:

1. Analytically, there is no difference between tax evasion ($0 < p < 1$) and tax avoidance ($p = 0$). This is the case because a penalty or, alternatively, the costs of avoidance affect the firm's payoff, namely, expected profits, qualitatively in the same way. Consequently, from now on, we will only refer to tax evasion, although the exposition obviously applies to avoidance activities as well.
 2. The firm's activity decision is separable from its evasion choice. That is, the model predicts, first, that the firm will always choose that level of economic activity, x^* , which it would have selected in the absence of evasion activities. Second, the optimal extent of tax evasion, E^* , is the same, irrespective of activity choices. Accordingly, large firms, which are characterized by a high activity level, under-declare the same amount as otherwise identical small firms which exhibit a lower activity level. Note that this separability feature will also arise if the audit probability, $1 - p$, depends on the under-declaration, such that $p = p(E)$, because the firm's optimal activity choice is still determined by (2a).
- The separability prediction is due to two features. First, the monetary gains from legal profits, π , and from tax evasion, $E t - (1 - p)C$, affect the firm's payoff in qualitatively the same way and do not reinforce or weaken each other. This is in contrast to usual findings
- with regard to tax evasion by individuals because an increase in activity, say in working time, reduces leisure which, in turn, alters the marginal utility from income (see ► [“Tax Evasion by Individuals”](#)). Second, the net gain from tax evasion, $E t - (1 - p)C$, is independent of the activity level, x .
- The empirical evidence on the lack of a correlation between firm size and tax evasion activities is mixed (Rice 1992; Nur-tegin 2008; Hanlon et al. 2007; Cai and Liu 2009; Tedds 2010; Hoopes et al. 2012). Since firm size in these studies is measured by the number of employees, value added, or assets, these measures are imperfect proxies for economic activity. Moreover, the costs of evasion may vary with firm size. Accordingly, the empirical findings do not necessarily provide comprehensive evidence with regard to the separability prediction.
3. A higher tax rate, t , will raise evasion activities as long as a rise in t does not increase the marginal costs of evasion, C_E , by more than $1/p$. This will, for example, always be the case if the costs of evasion depend neither on the tax rate ($C_t = 0$) nor vary with the amount of taxes evaded, $E t$. Accordingly, if adhering to the law becomes more expensive, violations of these regulations will become more severe. This is a straightforward and intuitive prediction which also generally obtains in standard models of the economic analysis of crime but does not always apply in the case of tax evasion by individuals (see Yitzhaki 1974 and the literature cited above in section [“Introduction”](#)). The theoretical prediction that higher tax rates induce firms to expand evasion activities is generally consistent with empirical findings (Rice 1992; Nur-tegin 2008; Cai and Liu 2009).
 4. If a higher fine, F , raises the marginal costs of tax evasion, so that $C_{EF} > 0$ holds, a rise in F will reduce tax evasion. A greater probability, $1 - p$, of being audited will have the same effect. The empirical evidence, although scarce, is consistent with these predictions (Nur-tegin 2008; Hoopes et al. 2012). Moreover, the separability feature implies that changes in tax enforcement have no impact on a firm's activity level.

5. The results outlined above are not affected by the type of tax considered (Yaniv 1995). Accordingly, the findings are independent of the tax base (such as corporate income, the payroll, value of property, sales, value added), the curvature of the tax schedule, and whether firms act as withholding agents or not. In addition, the theoretical analysis implies that empirical findings for one tax are applicable to others as well.

Robustness

Many analytical contributions of tax evasion by firms have investigated the robustness of the separability result and of its implications and have identified conditions under which the result will no longer hold. In terms of Eq. 1, this can be the case if nonlegal profits, π^N , are affected by a variation in activity, x , not only via official net profits $\pi(x, t)$, i.e., if $E t - (1 - p)C$ varies with activity, x . Such dependence can result under a variety of circumstances, and we discuss four of them below:

1. Assume that $p = p(x)$ holds. (Cf. Virmani 1989). This could be the case, for example, because tax authorities condition the audit probability, $1 - p(x)$, on firm size or because it is related to the frequency of transactions between buyers and sellers which, in turn, are positively correlated to activity. Instead of directly assuming a relationship between p and x , Lee (1998), Marrelli (1984), Marrelli and Martina (1988), and Wang (1990) indirectly include the activity level into the respective specification of the audit probability. Further, Bayer and Cowell (2009) derive such linkage on the basis of a relative auditing rule. According to this rule, the audit probability is positively related to tax payments by other comparable firms and their output levels in an oligopolistic market.

Given the modification of $p = p(x)$, the first-order conditions for a profit maximum are given by $\pi_x + p'C = 0$ and by (2b). If the audit probability, $1 - p(x)$, declines with

activity, because larger firms can avoid detection more easily, tax evasion will induce a firm to expand activity. Fighting tax evasion, for example, by raising the fine, F , and the marginal costs of evasion, C_E , will still reduce evasion activities for a given activity level. Therefore, the gain from an activity expansion will become less pronounced and the overall activity change in response to a higher fine will generally be ambiguous. Even more surprising, a rise in activity, x , enhances the gain, $(1 - p(x))C_E$, from evasion because of the decline in the audit probability. Consequently, the change in evasion activities resulting from a higher fine is also potentially ambiguous (Virmani 1989). Note finally that if knowing the activity level would enable tax authorities to infer the tax base, the assumption of $p = p(x)$ could be inconsistent with the notion of the firm being able to evade taxes. However, knowledge of activity, x , does not necessarily imply that the true tax base is known, unless they are perfectly correlated as, for example, in the case of a unit tax on output.

2. Assume, alternatively, that the firm is not free to choose the under-declaration, E , but can only select a fraction or multiple, e , of activity, x , so that $E = ex$. Such a situation may arise if activity is easily observable, for example, in the case of output levels. The first-order conditions for a profit maximum are given by $\pi_x - e(t - (1 - p)C_E) = 0$ and $t - (1 - p)C_E = 0$. Therefore, activity and evasion decisions are separable if firms can select e optimally. However, if institutional restrictions limit a firm's choice of e , $t - (1 - p)C_E \neq 0$ will hold, and the separability feature will no longer apply (Marrelli 1984; Wang and Conant 1988; Yaniv 1995). Since the restriction on evasion will only be relevant if it is binding, the above result suggests that firms which are easier to monitor and cannot choose e optimally will evade less tax, while evasion and activity choices will be related. The empirical evidence that state-owned companies (Nur-tegin 2008) and publicly traded firms (Rice 1992; Hanlon et al. 2007; Tedds 2010) evade less is consistent with this interpretation.

3. A relationship between economic activity and tax evasion can also arise due to market equilibrium effects. To illustrate, suppose that aggregate activity is positively related to profits because higher profits will induce more firms to enter the market. A higher fine, F , not only raises the costs of evasion ($C_{EF} > 0$) and reduces profits but also makes market entry less attractive. In consequence, the market structure will change along with any policy to reduce tax evasion, and such a policy may actually mitigate competition. Conversely, policies to enhance competition, such as the abolition of product market regulations, may have the detrimental effect of intensifying tax evasion activities by firms (cf. Cai and Liu 2009; Goerke and Runkel 2011).
4. Finally, consider the existence of principal-agent problems. They are likely to arise, for example, in firms run by managers. Managers are unlikely to maximize profits but will pursue their own objectives, at least to some extent. In the presence of such principal-agent problems, the objective function of the firm's decision-maker could be given by $\pi^N(x, E) + K$, where K represents the manager's additional objective. K may be increasing in x and could depend on the under-declaration, E . Moreover, K will vary with the fine and audit probability if the manager is legally or otherwise responsible for tax evasion activities by the firm. Hence, $K = K(x, t, E, F, p)$. Since the manager's first-order condition for a maximum with regard to output is given by $\pi_x + K_x = 0$, it is obvious that activity, x , may vary with tax enforcement and that separability may no longer hold if the decision-maker's marginal payoff is altered by evasion (i.e., if $K_{xE} \neq 0$). As a consequence, changes in the structure of corporate governance; the relative importance of the nonprofit objective, K ; restrictions on the level and composition of a manager's remuneration; and the manager's preferences can affect the choice of economic activity, x , and create a relationship, as well as influence the possible linkage between activity and tax evasion activities (see, e.g., Joulfaian 2000; Crocker and Slemrod 2005; Goerke 2007).

Future Directions

In lieu of a summary, we may speculate about future areas of research. For example, the interaction of evasion and avoidance behavior of individuals on the one hand and of firms and businesses on the other can play a greater role in the future. Moreover, the relationship between the structure of input and output markets and tax evasion by firms which are active on these markets is likely to become a more prominent topic. Furthermore, the ability of firms to shift activities across jurisdictions can affect tax evasion and avoidance behavior. In addition, firms are likely to have better outside options than individuals in negotiations with tax authorities. Such bargains between tax payers and authorities also appear to be a promising area of future work. Additionally, the consequences of the division of labor have been an issue which has hardly been looked at. The tax declaration may, for example, be decided upon by a different agent within the firm or outside its realm (think of tax preparers, etc.) than the one who determines the activity level. Such a separation of responsibilities will create additional principal-agent problems. When looking at individuals, recent years have seen intensified attempts to apply various facets of behavioral economics to the analysis of tax evasion (Hashimzade et al. 2013). This may also be an aspect which becomes relevant to the investigation of firm behavior (Alm and McClellan 2012). Finally, it is noteworthy that the economic analysis of crime focuses very much on normative issues. The question of how much tax evasion is optimal has not been an issue looked at intensively with reference to taxes remitted by firms. Hence, it can be conjectured that welfare issues will also play a more prominent role in the future.

Tax Evasion by Individuals

Abstract

The basic deterrence model of tax evasion is described, its main predictions are derived, and limitations and flexibility are outlined. Further, the model is interpreted in light of some key institutional features characterizing tax enforcement in OECD countries. Throughout the survey, findings originating from the deterrence model are contrasted with predictions which result from a simple model of criminal activity and law enforcement.

Definition

Tax evasion by individuals represents the attempt to illegally reduce the payment of taxes which

have to be remitted by an individual tax payer to below the level prescribed by law.

Introduction

The analysis of income tax evasion by economists has covered many issues, and most extant surveys focus on a selection of relevant aspects (see, e.g., the contributions by Andreoni et al. (1998), Alm (1999, 2012), Cowell (2004), Slemrod and Yitzhaki (2002), Marchese (2004), Slemrod (2007), Franzoni (2009), and Sandmo (2012)). In many of these reviews, the investigation of tax evasion is interpreted as a special case of the approach which is employed in the economic analysis of crime. In this survey, we explicitly adopt such a perspective and relate findings originating from the analysis of income tax evasion to the broader economics literature on crime. In doing so, we first take a theoretical perspective, present the basic deterrence model of tax evasion, derive its main predictions, and indicate its restrictions as well as the analytical flexibility. Second, we adopt a more institutional viewpoint and confront the theoretical predictions with basic features of real-world enforcement systems. Finally, we compare selected aspects which are discussed in both the literature on tax evasion and the public enforcement of law (as reference for the literature on the public enforcement of law, we use the article in the *Handbook of Law and Economics* (Polinsky and Shavell 2007)).

Basic Theory

We consider a representative, risk-averse individual who is endowed with an exogenously given income Y . This income represents the tax basis and is subject to a linear tax at the rate t . The individual can decide on the amount of income X he/she does not report to tax authorities. Therefore, the gain from evading taxes will equal Xt if tax evasion remains undetected. This takes place with an exogenously given probability p , $0 < p < 1$, and the individual's income then amounts to $Y^s = Y(1 - t) + Xt$. With the opposite

probability, $1 - p$, the individual or taxpayer will be audited, and tax evasion will be detected. In this case, a fine F is imposed, and the resulting income equals $Y^c = Y^s - F$. While the fine is assumed to be a function of undeclared income X in the seminal contribution by Allingham and Sandmo (1972), Yitzhaki (1974) argues that the penalty is usually based on the amount of taxes evaded, Xt . Consequently, we define the fine F as a linear combination of both determinants, $F := fX[\alpha t + (1 - \alpha)]$, where $f, f > 0$, is labeled marginal fine. The parameter α , $0 \leq \alpha \leq 1$, depicts the relative importance of the amount of taxes evaded. For $\alpha = 1$ (0), this implies that the fine is solely a function of taxes evaded (undeclared income). The specification of F reflects the fact that the penalty rates in many OECD countries vary with amount of undeclared taxes but include fixed components or change with other determinants than the underdeclaration (OECD 2009, p. 136 ff). As the final building block, we assume that utility u is increasing in disposable income at a decreasing rate, $u' > 0 > u''$, and that the individual can be described by von Neumann-Morgenstern preferences. Accordingly, expected utility $U(X)$ is given by

$$U(X) = pu \underbrace{(Y(1 - t) + Xt)}_{:=Y^s} + (1 - p)u \underbrace{(Y(1 - t) + Xt - fX(\alpha t + 1 - \alpha))}_{:=Y^c} \quad (1)$$

Maximizing U with respect to the underdeclaration, X , yields as first-order condition

$$U'(X) = pu'(Y^s)t + (1 - p)u'(Y^c)(t - f(\alpha t + 1 - \alpha)) = 0 \quad (2)$$

The first term in Eq. 2 describes the utility gain from underdeclaring an extra unit of income if tax evasion is successful, while the second term depicts the loss because income declines when being punished. The underdeclaration which results when these two effects are balanced out

is indicated by X^* . Note that there will only be an underdeclaration if the gain from evading the first euro of taxes is positive, that is, if $U'(X)$ is greater than zero for $X = 0$ and, hence, for $Y^s = Y^c$. This implies that there is an upper level for the marginal fine $f_{\max} = t/[(1 - p)(\alpha t + 1 - \alpha)]$. Furthermore, tax evasion will only be costly if disposable income Y^c shrinks with the underdeclaration in the case of detection. Accordingly, there is a minimal marginal fine $f_{\min} = (1 - p) f_{\max} = t/(\alpha t + 1 - \alpha) > t$. The setting described above focuses on tax evasion. While evasion is the illegal attempt to reduce tax payments, tax avoidance is often interpreted as its legal counterpart. By setting the detection probability, $1 - p$, equal to unity and adding a cost function which increases in the amount of taxes avoided at an increasing rate, the above framework can be amended in order to analyze tax avoidance. Furthermore, many findings derived with regard to tax evasion also hold in an avoidance setting.

Central Results

How does the optimal underdeclaration, $X^* > 0$, vary with income, Y , the parameters of the tax enforcement system, p and f , and the tax rate, t ? The respective effects often depend on whether the fine, F , varies with the tax rate, t , i.e., on the value of the parameter α and on the relationship between income and the Arrow-Pratt measure of absolute risk aversion, $R_a(Y) := -u''(Y)/u'(Y)$.

Income, Y , exerts a positive impact on the optimal underdeclaration, X^* , if the individual exhibits decreasing absolute risk aversion, R_a , that is, if the willingness to engage in risky activities rises with income. To provide an intuition, note that a higher exogenous income, Y , raises disposable income for a given underdeclaration, irrespective of whether tax evasion is detected or not. If this general increase in income makes the individual more willing to take risks, the gain from higher income shrinks by less than the costs in terms of utility. Therefore, the optimal underdeclaration, X^* , rises. Since the tax basis, Y , becomes larger, the amount of taxes paid, that is, $(Y - X^*)t$, may nevertheless increase. If, however, absolute risk aversion, R_a ,

does not vary with income, there is no income effect, and the underdeclaration remains constant, while the amount of taxes paid surely increases.

A higher marginal fine, f , and a greater detection probability, $(1 - p)$, both reduce the optimal underdeclaration, X^* . If the marginal fine, f , rises, two consequences strengthen the incentives to pay taxes. First, there is an income effect since a higher fine payment decreases disposable income, Y^c , if evasion is detected. Therefore, the marginal utility of income in this state of the world rises, and the utility loss resulting from the fall in income if penalized becomes larger. Second, the penalty on the last euro of underdeclared income rises. A higher probability of detection, $1 - p$, makes it more likely that an income loss occurs. Consequently, the individual responds by reducing the loss in disposable income if this more likely event takes place.

The consequences of a higher tax rate, t , hinge on the specification of the fine and on absolute risk aversion, R_a . Suppose, initially, that the fine, F , depends on the amount of taxes evaded ($\alpha = 1$). The optimal underdeclaration, X^* , will decline with the tax rate, t , if the individual exhibits constant or decreasing absolute risk aversion, R_a , while the impact is theoretically ambiguous otherwise. For $\alpha = 1$, F is a multiple of the tax rate, t . Accordingly, a rise in t alters the gain and costs from evasion proportionately. Therefore, the impact of the tax rate, t , on the optimal underdeclaration, X^* , is solely determined by the income effect. A higher tax rate, t , reduces disposable income and does so more if evasion is detected than if it remains unobserved. If a decline in income, in turn, raises absolute risk aversion, the optimal underdeclaration, X^* , will shrink. If, alternatively, the fine, F , depends on the underdeclaration ($\alpha = 0$), X^* will rise with the tax rate, t , if absolute risk aversion, R_a , is constant or increasing with income, while the relationship will once again be ambiguous otherwise. In this case, a higher tax rate, t , reduces the penalty relative to the gain from evasion, namely, the lower tax payment. A relative decline in the penalty induces the individual to raise the underdeclaration, X^* , *ceteris paribus*. This substitution effect will be mitigated or reversed by the

income effect which provides greater incentives to underdeclare if absolute risk aversion is declining with income.

While the above analysis has assumed a representative individual, one can easily incorporate heterogeneous taxpayers, for example, in terms of gross income, Y ; the degree of absolute risk aversion, R_a ; or the marginal tax rate, t . Thus, the analytical model can be used to predict that individuals facing a higher marginal tax rate, t , are more likely to evade and not to pay any taxes, since the maximal and the minimal fines $f_{\max}$ and $f_{\min}$ increase with t for $\alpha < 1$.

Relating the predictions derived above to the findings obtained in the analysis of crime, it may be observed that the model of criminal activity often employed is based on the assumption that a crime is either committed or not, while the extent of criminal activity per individual is constant. Higher fines and a greater detection probability reduce the incentives to undertake criminal actions, while a higher potential gain will raise them. The latter prediction may be compared to a change in the tax rate, t , derived above. The impact of a higher gross income, or of wealth, depends on whether income also increases disposable income when the criminal is penalized, *inter alia*. However, the degree of risk aversion does not play a role in the basic setup. These partial differences with respect to the effect of changes in exogenous parameters indicate that predictions can depend crucially on the underlying view of the illegal activity. Does it represent a simple portfolio choice with one safe and another risky asset, as in the case of tax evasion, or does it constitute an endeavor which can be separated from other income-generating activities?

Extensions

The basic deterrence model of income tax evasion has been expanded in numerous ways. We subsequently sketch two extensions which further clarify the sensitivity of the predictions but also the flexibility of the analytical approach. First, we incorporate the idea that individuals will generally

be able to decide on the amount of gross income they earn. This decision is likely to result from a trade-off between higher disposable income on the one hand and a greater disutility from generating this income on the other. Hence, utility may be given by $U(Y^s, Y)$ and $U(Y^c, Y)$, depending on whether evasion is detected or not. In addition, $\partial U / \partial Y < 0$ captures the disutility of generating income. In an early contribution, Pencavel (1979) showed that virtually all predictions developed above will not necessarily hold in such a setting. The reason is that any activity which makes tax evasion less attractive also reduces the incentives to generate income. This reduction in the tax base, in turn, lowers evasion activities for a given underdeclaration and, hence, strengthens the incentives to evade. The net effect is generally uncertain because of the differential changes in the marginal utility of disposable income (i.e., $\partial U / \partial Y^s$ and $\partial U / \partial Y^c$) and from generating Y (i.e., $\partial U / \partial Y$). This first extension is an impressive example of the sensitivity of predictions with regard to incorporating additional choice variables.

The individual considered above has occasionally been termed an “amoral tax payer” (Crocker and Slemrod 2005, p. 1595), because the tax evasion decision results solely from the comparison of monetary gains and losses. Therefore, secondly, the question arises how the optimal underdeclaration will be affected if there is a norm with regard to paying taxes. In a simple extension of the basic model, it can be presumed that tax evasion imposes a utility loss on individuals who evade taxes. It has, *inter alia*, been assumed that this loss (1) is constant, (2) increases in the extent of individual tax evasion, (3) depends on how tax revenues are spent, or (4) varies with an aggregate measure of tax evasion (see Alm and Torgler 2011). While the existence of a norm imposes additional costs of tax evasion in cases (1) and (2) and, therefore, mitigates such activities, the impact in cases (3) and (4) is less obvious. This can be illustrated by assuming that the utility loss from violating the norm of paying taxes varies across individuals and becomes weaker the more people evade taxes. Then, the model may have (at least) two equilibria. In the first, many or all individuals evade taxes, and the

norm does not really bite. In the other equilibrium, few individuals evade taxes. Therefore, the norm imposes substantial costs of evasion, and this helps to stabilize the equilibrium with few people underdeclaring income. In such a setting, the impact of changes in exogenous parameters can be reversed. To illustrate, suppose that higher fines weaken the societal norm of paying taxes. In this case, more severe penalties will reduce evasion, *ceteris paribus*, but weaken the norm and may induce a move from a low-evasion to a high-evasion equilibrium. In this case, the standard prediction that higher fines reduce illegal activities may no longer hold. This second extension clarifies that the standard deterrence model of tax evasion is flexible enough to be applicable to taxpayers whose preferences include non-monetary components such as norms.

An Institutional Perspective

Given the importance of the assumptions underlying the model presented above, it is instructive to view them in light of essential features characterizing real-world tax and enforcement systems. In most OECD countries, the nominal income tax rises with income, suggesting that the tax system is progressive. Moreover, the marginal tax burden on wages, taking into account exemptions and government benefits, also generally rises with income, although the marginal rate may decline at specific income levels (OECD 2013). Therefore, the tax rate depends on gross income, $t = t(Y)$, or declared income $Y - X$ in the case of successful evasion. Since it would be optimal to overdeclare income if the marginal tax rate is negative, increasing marginal tax rates have usually been analyzed. While the impact of changes in the enforcement system is generally unaffected by the nature of the tax system, the consequences of changing the marginal tax rate or the progressivity of the tax schedule can also depend on what individuals decide on, namely, the magnitude of the underdeclaration (as in this setting) or of voluntary tax payments (cf., e.g., Yitzhaki 1987; Goerke 2003). Consequently, the tax schedule on its own may affect tax evasion.

The penalty rates in many OECD countries are considerably lower than 100%, even for severe cases of tax evasion (OECD 2009, p. 136 ff). Additionally, the cursory evidence available suggests that the detection probability with regard to income tax evasion is perhaps as low as 1% (see Slemrod 2007 for corresponding information for the United States). In order to integrate this information into the analytical setup, suppose that the utility function u is given by $u(Y) = Y^{1-a}/(1-a)$ and hence features constant relative risk aversion, $R_r(Y) := -u''(Y)Y/u'(Y) = a$. Moreover, the fine is a function of the amount of taxes evaded ($\alpha = 1$); the marginal fine, f , equals 2; the detection probability is assumed to be 10% ($p = 0.9$); and the tax rate is set to $t = 1/3$. Substituting these values into the basic model (cf. Eqs. 1 and 2), the fraction of gross income, Y , which is optimally underdeclared will only be less than 100% if relative risk aversion, R_r , exceeds two. Moreover, the optimal underdeclaration shrinks with R_r , given the above specification of the utility function. If, for example, a value of $R_r = 10$ is assumed, the individual would still underdeclare about 22% of the gross income. Therefore, it has been argued that the standard model seriously overpredicts tax evasion for plausible values of relative risk aversion, R_r , such as between one and five, given the parameters of the tax enforcement system observed in most countries (cf. Alm et al. 1992; Feld and Frey 2002, *inter alia*).

The response to this criticism has been manifold: Firstly, it has been argued that the payoff of taxpayers is not only affected by the monetary gains and cost of evasion activities but also by the gain of adhering to, or the cost of violating, a social norm, as outlined above. Moreover, the gain may be altered, for example, by whether taxpayers can decide on and approve of the use of tax revenues or how they perceive tax authorities. Secondly, the use of alternative specifications of preferences has been suggested, such as rank-dependent expected utility or prospect theory (cf. Alm and Torgler 2011; Hashimzade et al. 2013). Thirdly, it has been maintained that the numerical example provided above is not an appropriate one with regard to the decision of wage earners but only with respect to self-employed or small businesses (Slemrod 2007).

Wage income is generally subject to withholding regulations. Therefore, the probability that evasion of such income will be detected may approach 100%. A detection probability of 50%, however, would eradicate all evasion incentives in the above numerical example, and the deterrence model of tax evasion can, thus, be reconciled with the data.

Tax Evasion and the Economics of Crime

As mentioned at the outset, the investigation of tax evasion is often interpreted as an application of the economic analysis of crime. However, the perspectives of the two approaches are fundamentally different. A large majority of contributions on tax evasion ask either positive or incrementally normative questions, such as how the tax structure affects evasion activities or whether a certain tax structure is to be preferred to another (see, e.g., the survey by Slemrod and Yitzhaki (2002), in which only one (long) out of eight sections deals with normative issues). The economic analysis of crime focuses strongly on the enforcement of legal rules by public institutions, and the “general problem of public law enforcement may be viewed as one of maximizing social welfare” (Polinsky and Shavell 2007, p. 406). A basic result of this approach is that in the presence of risk-neutral individuals and monetary fines, which have no direct welfare effects, the optimal expected monetary fine should equal the harm caused by a crime. If the sanction is non-monetary, such as a prison sentence, the expected penalty should be lower because a nonmonetary sanction increases enforcement costs and, thus, lowers welfare.

In the analysis of tax evasion, however, such normative issues have played a comparatively minor role. In one important exception, Slemrod and Yitzhaki (1987) inquire as to what the optimal size of a tax collection agency is in the presence of risk-averse individuals. For a given amount of tax revenues, less tax evasion mitigates income variability, and this reduction in the “excess burden of tax evasion” (Slemrod and Yitzhaki 1987, p. 187) represents the welfare gain from reducing evasion activities. Higher enforcement costs constitute the

welfare loss due to fighting tax evasion. The optimal degree of law enforcement is attained when the revenue effect of stricter enforcement still exceeds the resource costs of achieving this revenue impact. The reason is that the revenue gain is mainly distributionary and has no direct welfare impact in a setting with identical individuals, while costs of enforcement reduce welfare. This finding resembles those obtained in the economic analysis of crime.

Given the different perspectives, the literature on tax evasion and the contributions on public law enforcement have also approached many extensions of the basic settings in alternative ways. To illustrate, we consider the nature of penalties and settlements.

From an economics of crime perspective, non-monetary sanctions, such as prison sentences, can have two advantages over fines. Firstly, the financial means of a tax evader may be insufficient to pay a fine. However, imprisonment is feasible irrespective of wealth so that nonmonetary penalties may still deter illegal activities when monetary fines no longer have this effect. Secondly, imprisonment generally limits future crimes. Such an incapacitation effect is less likely to occur in the case of monetary penalties. One important disadvantage of nonmonetary penalties is the higher cost of enforcing such penalties. In most countries, the penalties for evading personal income taxes are represented by monetary fines. However, for severe cases of tax evasion, prison sentences can also be imposed (cf. OECD 2009, Table 31). Nonetheless, questions such as (1) what are the effects of monetary and nonmonetary penalties on tax evasion?, (2) when should imprisonment be used and sentences be suspended?, and (3) what is the optimal combination of fines and imprisonment? have not figured prominently in contributions on tax evasion. This is in contrast to the literature on public law enforcement.

Settlements, that is, agreements between an offender and authorities to terminate or avoid a court trial in exchange for accepting a penalty, have received substantial attention in the economic analysis of crime. Settlements can be desirable because they reduce the costs of law enforcement. Furthermore, risk-averse individuals may prefer

certain penalties to uncertain court outcomes. The main disadvantage of settlements is that they will be attractive to offenders only if they effectively imply a lower penalty. This dilutes the deterrence effect of sanctions. In addition, a settlement may hinder the detection of all illegal activities of an offender and can prevent the development of precedents. While such aspects of settlements have been discussed in the literature on the public enforcement of law (Polinsky and Shavell 2007, p. 435 f), there are few relevant contributions relating to tax evasion (Macho-Stadler and Pérez-Castrillo 2004; Franzoni 2004).

The relative infrequency of settlements may be due to the fact that trials in cases of tax evasion are much less frequent than for criminal activities such as theft, fraud, physical injury, or murder. However, the perspective can also be reversed. Often, tax authorities impose a penalty. This procedure may be interpreted as the tax authority's (pretrial) proposal of a settlement. Accordingly, the relevant question in the context of tax evasion may not be whether settlements are beneficial but why they are used so extensively.

The two above examples clarify that the investigation of topics analyzed in the public enforcement of law may also generate additional insights in the context of income tax evasion. Other such issues may relate to the self-reporting of past tax evasion activities, the treatment of repeat offenders, the employment of tax advisors, corruption among enforcement agents, and the role of marginal deterrence. The analysis of such topics will be especially rewarding if institutional features of tax evasion activities are taken into account. Such investigations would help to clarify whether or not predictions based on general models of illegal behavior carry over to the more specific settings applicable to the investigation of income tax evasion.

Telecommunications

Alden F. Abbott
Heritage Foundation, Washington, DC, USA

Abstract

Telecommunications involves the transmission of information without change in the form or content. Telecommunications networks increase in value as the number of users rises (“network effect”) and the rise of the Internet and wireless communications has bestowed huge economic benefits on countries worldwide. The development of telecommunications has been heavily influenced by regulatory regimes. Regulation in the United States has featured efforts to restrain private monopoly power and promote market allocation of spectrum, while European regulation recently has focused on the privatization of former state telecommunications monopolies and the transition to a pan-European regulatory regime. As the United States transitions away from US government stewardship of the Internet and toward a more global form of Internet governance, the International Telecommunication Union is seeking to play a greater role in Internet oversight. Emerging telecommunications policy issues include

the privatization of the radio spectrum, “net neutrality” regulation aimed at treating all data traffic equally, and the growth of “cloud computing” and “big data” compilations.

Conceptual Overview

Telecommunications may be broadly defined as “the transmission, between or among points specified by the user, of information of the user’s choosing, without change in the form or content of the information as sent and received” (47 U.S. Code § 153 [2011](#)). The information transmitted may take the form of data, text, audio, and/or visual materials.

Whether the telegraph, the telephone, or the Internet, the full value of a telecommunications medium may not be realized until there is a network of users that can transfer information among themselves. This addition in value can be attributed to what is known as a “network effect.” There is a significant difference, however, between network effects and network externalities. While the term “network effect” refers to the increase in the value of a network that corresponds with the increase in the number of participants in the network, “network externalities” occur when market participants do not fully “internalize” (obtain) that increase in value, for example, the owners of a private network (Liebowitz and Margolis [1998](#)).

The network effect is an example of a positive externality, in which the action of one individual benefits another individual without any mutual agreement to make compensation for that benefit (Easley and Kleinberg [2010](#)). A prime example is the benefit gained from additional participants in a social networking site, which raises the potential for any given individual to network through that site, even though no participant is explicitly compensated for joining (Easley and Kleinberg [2010](#)). The Internet illustrates the network externality of the social media to a grand degree, with over 200 million Americans having broadband access to the Internet (Broadband Fact Sheet Pew Research Center [2013](#)) and an estimated 2.9 billion Internet users worldwide (International

Telecommunication Union Key ICT Data 2005 to 2015), bringing major economic benefits with it. The Internet “alone accounted for 21% of the GDP growth in mature economies from [2006 to 2011]”: Brazil, Canada, China, France, Germany, India, Italy, Japan, Korea, Russia, Sweden, the UK, and the United States (Manyika and Roxburgh 2011). According to one study, among such “high-income” economies from 1980 to 2002, “a 10% increase in broadband penetration yielded an additional 1.21 percentage points of GDP growth,” while the same level of broadband penetration in “low- and middle-income economies” yielded 1.38 percentage points of GDP growth (International Telecommunications Union Impact of Broadband 2012).

This value of an established network due to an existing pool of participants has led some to worry that an earlier-created inferior product with a pre-existing network of participants would win out against a later-arriving but superior product without such a network. If two competing networks produce similar but incompatible products, the product with the greater market share will have an advantage. If the network effect does not diminish, the advantaged network could be seen as a natural monopoly (Liebowitz and Margolis 1998).

However, the network effect is not limitless. If additional participants cease to provide value to the existing network of participants, meaningful competition among networks may be possible. Subjective valuation of the network by individuals may also differ, allowing multiple competing networks to coexist (Liebowitz and Margolis 1998). Similarly, different individuals may value individual participants added to the network differently, which could provide an opening in the market for separate networks to serve different groups based on the actual makeup of the participants (Liebowitz and Margolis 1998).

The United States and Europe possess the most mature telecommunications regulatory regimes. An overview of these systems provides insight on the sorts of problems national governments face as they oversee the development of their telecommunications sectors. Following the overview, this essay briefly describes international telecommunications regulation and emerging policy issues.

Telecommunications Regulation in the United States of America (USA) and the European Union (EU)

In one of the first attempts to regulate telecommunications as a whole, the US Congress passed the Communications Act of 1934, establishing the Federal Communications Commission (FCC) to take responsibility for regulating radio and wire communications, which had previously been dealt with by separate agencies (Communications Act of 1934). Congress amended the law with the Telecommunications Act of 1996, allowing for federal preemption of local regulations that acted as barriers to entry and more competition in the long-distance market and requiring incumbents to allow access to their networks at wholesale prices (Telecommunications Act of 1996). The FCC also has oversight over wireless services and radio and television broadcasting (“What We Do,” Federal Communications Commission 2015), which are licensed to use certain portions of the electromagnetic spectrum.

In 1974, the Department of Justice sued under the Sherman Antitrust Act to rein in the dominant US national telecommunications company, in filing suit against AT&T to modify an existing 1949 consent order. The suit alleged that AT&T, the monopoly provider of local telephone service in most parts of the United States, had engaged in various anticompetitive acts to maintain monopoly power in the provision of long-distance telephone service (*U.S. v. AT&T* 1978). The suit ended in divestiture for AT&T in a modified consent decree in 1983, effectively breaking up the telecom giant (*U.S. v. AT&T* 1983). Since 1983, additional antitrust actions have been directed at major US telecommunications companies. For example, in 1998, the United States sued under the Clayton Antitrust Act to block the merger of AT&T with TCI (the merger went forward subject to a consent agreement) (*U.S. v. AT&T* 1999), and Verizon was sued under the Sherman Antitrust Act for conduct that had been found to violate the Telecommunications Act of 1996 (the antitrust suit failed) (Verizon Communications 2004).

The telecommunications regulatory regime in the United States receives policy advice and technical support from the National

Telecommunications and Information Administration (NTIA), established in 1978. The NTIA advises the President and works with executive branch agencies to develop policy on telecommunication and information issues and manages the federal use of the electromagnetic spectrum by administering grants and holding auctions to assign licenses (About NTIA 2015) (the NTIA has worked with the FCC to reassign certain spectrum frequencies from public use to private use). The NTIA also has been indirectly involved in Internet governance (and, in particular, the administration of the Internet Domain Name System) through its administration of a US government contract with the Internet Corporation for Assigned Names and Numbers, or ICANN, and the Internet Assigned Numbers Authority, or IANA (ICANN 2015).

In Europe, telecommunications was mostly provided by state-owned monopolies until the 1970s, when pushes for a smaller role for governments in the telecommunications market began to rise (Bauer 2013). In the 1980s, the European Commission began to promote a vision of a pan-European telecommunications sector (Bauer 2013). The EU successfully liberalized terminal equipment, value-added, and other services and had opened all services up to competition by 1998 (Bauer 2013). By 2012, all but one member, Luxembourg, had at least partially privatized their telecommunications sector (Bauer 2013). Since then, the European Union has moved toward facilitating regulation and standardization of telecommunications throughout EU member states as part of the *Digital Agenda for Europe*. The EU's framework is made up of five directives, the Framework Directive, the Access Directive, the Authorisation Directive, the Universal Service Directive, and the Directive on Privacy and Electronic Communications, and two regulations, the Regulation on Body of European Regulators for Electronic Communications (BEREC) and the Regulation on Roaming on Public Mobile Communications Network (Digital Agenda for Europe Telecoms Rules 2015). In 2012, the European Parliament and Council approved the first Radio Spectrum Policy Programme (RSPP) to set objectives, make recommendations, and establish principles for the administration of the radio spectrum

(Digital Agenda for Europe Radio Spectrum Policy Program 2015). The overall aim of these efforts is to move toward a pan-European approach to telecommunications regulation, in place of the nation-specific regulatory regimes that currently exist within the EU.

Other jurisdictions throughout the world employ a variety of regulatory schemes, with the trend being toward provision of telecommunications services through private operators rather than the state (Struzak 2003). The recent fast international growth of mobile wireless telecommunications, which has rapidly spread the availability of telecommunications services to new populations (especially the poor), is another feature that is expanding the telecommunications network effect and, in particular, widespread access to the Internet.

International Telecommunications Regulation

While the United States has historically acted as steward of the Internet, the NTIA has received pressure to move toward a more global model of Internet governance. As a step toward this model, the NTIA asked ICANN to turn over its role in coordinating the Internet's Domain Name System (DNS) to the international community as part of a program of privatization (NTIA Announces Intent to Transition 2014). In so doing, the NTIA, acting consistently with resolutions of the US Senate and House of Representatives (S. Con Res. 50, 112th Cong., 2012), specified that it would not support handing its responsibility to any governmental or intergovernmental. The current contract expires on September 30, 2015. Some commentators have expressed concerns about the implications of this transition for the future of Internet governance (Schaefer et al. 2015), while others support NTIA's initiative (Llansó 2015; Tennenhouse 2014).

The International Telecommunication Union (ITU), founded in 1865 as the International Telegraph Union (International Telecommunication Union History 2015), is now a United Nations Agency focused specifically on information and communication technologies (ICTs). The

organization has proposed to take up the mantle of the NTIA, resolving to “to explore ways and means for greater collaboration and coordination between ITU and relevant organizations involved in the development of IP-based networks and the future Internet, through cooperation agreements, as appropriate, in order to increase the role of ITU in Internet governance so as to ensure maximum benefits to the global community,” specifically mentioning ICANN in its 2014 Plenipotentiary Resolution 102 (ITU Plenipotentiary Resolution 2014).

Emerging Policy Issues

Proposals to increase privatization of the radio spectrum and to regulate more heavily the provision of Internet communications are the subject of considerable recent debate. While auctions have been the chosen method of allocating newly privatized spectrum blocs in the United States, the process is not without controversy. For example, after a January 2014 auction for wireless licenses, AT&T accused Dish Network Corporation of intentionally driving up the price of spectrum licenses at auction, arguing that the coordinated bidding strategy involving three entities artificially inflated the perceived demand for the licenses. Dish Network asserted that it fully complied with FCC rules when implementing the bidding strategy, but there have been calls for the FCC to intervene to prevent such behavior (Gryta and Ramachandran 2015).

More generally, some commentators have advocated in favor of “net neutrality,” the principle that Internet service providers (ISPs) should treat all data traffic equally, in the regulation of ISPs (Lessig and McChesney 2006). On February 26, 2015, The FCC adopted a rulemaking that would, among other things, classify the Internet as a “public utility” regulated under Title II of the US Telecommunications Act, invoking the cause of net neutrality. In so acting, the FCC opined that in absent regulatory action, the Internet service providers may throttle data speeds based on content or offer high-paying customers prioritization in data traffic (FCC News Release 2015). Opponents voice concern that the regulation of the

Internet as a public utility will result in the entrenchment of larger Internet service providers (ISPs) at the expense of smaller providers, a slowdown in Internet speeds (or the rate of increase in speeds), and Internet access rates (Summary of Pai Testimony 2015). The rule is likely to face challenges from opponents, and the future of Internet regulation by the FCC remains uncertain (Hughes 2015). Concerns about imposing “net neutrality” and various other constraints on the provision of Internet service may be expected in other jurisdictions as well.

Ongoing changes in telecommunications infrastructure will also drive policy debates. Commentators have predicted the increased use of cloud services, investment in telecommunications infrastructure, and replacement of telephone lines with broadband in the developed world and with the rise in multi-device telecommunication services (Lopez 2015). The problem of “big data,” or collections of information that “had grown so large that the quantity being examined no longer fit the memory that computers use for processing,” has been a focus of discussion among telecommunications experts (Pflugfelder 2013; International Telecommunications Union Press Release December 2014).

Conclusion

The importance and diffusion of telecommunications services may be expected to grow apace, with the rapid expansion of wireless services and Internet-related transactions. This development promises to bestow large and growing benefits on producers and consumers worldwide. Nevertheless, questions about the future of Internet governance and regulation in general create some uncertainty as to the manner in which telecommunications (and, in particular, Internet) service provision will grow and evolve.

Television Market

Paola Savini

Autorità per le garanzie nelle comunicazioni – AGCOM, Rome, Italy

Definition

The television market is made up of content producers, broadcasting network operators, packagers and TV service providers, carriers and network providers, as for the supply side, as well as the so-called “audience,” for the demand side. It is a complex TWO-SIDED market, mature and strongly regulated. It is characterized by cultural, political, and industrial elements. These different components are deeply rooted within the national television markets but, at the same time, respond to global economic dynamics and supranational laws. The television industry can be divided into three main activities, corresponding to three different economic functions. These are the programs’ production, the organization of television programs in a schedule, and signal distribution in the territory. Almost a century after its invention and standardization, television is nowadays evolving again, as the competition provided by

newer and different screens (pc, smartphone, tablet) is increasing, thus offering the audience multiple options to access linear and on demand audiovisual contents.

Television Market: An Overview

In 2016, the European Union hosts more than 4,000 television services (European Audiovisual Observatory 2017), ranging from the historical generalist channels to the thematic ones, offering sports, film and series, children’s programs, and documentary to millions of habitants. Also many Video on demand service providers operate within the European countries, and hundreds of such services are available everywhere (Ofcom 2016).

The one-century old television is, in fact, still the mass medium *par excellence*, offering entertainment and information worldwide and accounting for about 20% of the not-sleeping hours in many countries (Ofcom 2017). Most countries currently license a high number of television channels which can operate at a national or sub-national (local) level, now accessible via different platforms, such as the digital terrestrial television (DTT), the cable, the satellite, or the Internet protocol television (IPTV), giving to the public the chance, never experienced before, to watch a huge variety of audiovisual contents. This audiovisual consumption may now happen through the TV set, but also on mobile devices, personal computers, tablets, or game consoles.

All of these changings are both technology and policy driven, as more than other media, television is characterized by cultural, political, and industrial elements (see entry on ► “Media”). These different components are deeply rooted in the national contexts of each television company (hereinafter, also called “broadcasters”) but, at the same time, respond to global economic dynamics and supranational laws (Freedman 2008).

Legal Framework

As regards the legal framework, numerous forms of public authorities exercise some kind of regulation over broadcasting activities, at different levels: apart from national legislative Chambers,

which regulate particularly the governance of the Public Service Media (PSM) and the content' level, there are the Communitarian institutions within the EU framework, some governmental administrative authorities, some independent regulatory authorities (see EPRA – European Platform of Regulatory Authorities – 52 authorities from 46 countries are members – which cooperates with the European Commission, the Council of Europe, the European Audiovisual Observatory and the Office of the OSCE Representative on Freedom of the Media), as well as the national Courts for specific issues. Within some Member State, also some forms of self-regulation apply, especially for Public Service Media.

Media ownership and concentration issues have traditionally been regulated at national level, with regard to media pluralism and freedom of expression in particular. However, some common principles may be found within the “*EU Charter of Fundamental Rights*” (Article 11) and within the “*European Convention for the Protection of Human Rights and Fundamental Freedoms*” (Article 10).

Differences are huge between European countries, as concerns media ownership: in France, some limitations apply both to the ownership of a single television channel and to the ownership of the number of licenses; in Italy, limitations apply both to the cross-ownership between national and local terrestrial channels and to the revenues within the media sector; in Germany, audience market share limits apply.

Concerning other issues such as programming, advertising, sponsorship, and the protection of certain individual rights, some Council of Europe countries signed already in 1989 the “European Convention on Transfrontier Television” (ETS n.132), which created a legal framework for the free circulation of transfrontier television programs in Europe. In particular, the Convention defined for the first time “audiovisual works of European origin” as the “creative works whose production or co-production is controlled by natural or legal European producers.”

Then, at EU level and with the neighboring countries, in 1989 it became effective a

coordination of national legislations on all audiovisual media, through the so-called “*Television Without Frontiers Directive*” (Directive 89/552/EEC), which aimed to safeguard some public interest objectives, such as cultural diversity, the protection of minors, and the right of reply, and rested on two basic principles: the free movement of European television programs within the internal market and the requirement for TV channels to reserve, whenever possible, more than half of their transmission time for European works (the so-called “broadcasting quotas”).

Having been this Directive substantially amended several times during the years (it is currently again under revision, and a new legislative proposal has been adopted by the European Commission on 25 May 2016), a minimum set of common rules applying to all the 28 Member States, it is now operating for the audiovisual and new media sector in the Union, based on the country of origin principle, ensuring freedom of reception and retransmission of the TV channels as well as advertising regulation, promotion of European works, and protection of minors (AVMSD 2010). All audiovisual media services providers (both television broadcasts and contents selected by viewers on-demand over an electronic communication network) shall display clearly their name and address and need to respect the basic rules provided in the AVMSD, as regards: the prohibition of incitement to hatred based on race, sex, religion, or nationality; the accessibility for people with visual or hearing disabilities; some qualitative and quantitative requirements for commercial communications.

At an even more international level, global radio spectrum and satellite orbits as well as technical standards are regulated by the International Telecommunication Union (ITU), the United Nations specialized agency for information and communication technologies.

Industrial Innovations

As regards the industry level, since the 1970s, technological innovations strongly fostered the enlargement of the television market, generally born as state-owned, and enriched the consumers' experience.

In 1962 the first transatlantic transmission, via the Telstar communications satellite, was made, permitting satellite images to be taken from around the globe. The first videotape recorders were sold to the public in 1965. Color broadcasting began in the USA in 1964. In 1972, the first digital converter changed pictures from the US 525-line format into the 625-line European standard. In the same year, the first cable operators appeared in the USA. An audience measurement system was implemented in the USA in 1973 and the UK in 1977 (the British Audience Research Bureau was created in 1981).

At the beginning of 2000, digitalization burst onto the scene as a disruptive innovation that would be able to revolutionize the entire TV ecosystem once again, at various levels of the TV supply chain. This technological innovation has been institutionally recognized as pro-competitive and thus as having positive direct and indirect influences on media pluralism, as a result (Adda and Ottaviani 2005). For the past 30 years the replacement of analog technologies with digital ones has indeed changed the transport systems of the signal: a long process of redefinition for transmission standards has been set up more recently (2009–2015), for the final switch off of the analogue signal, in the OECD countries. Digital terrestrial television was launched in the UK in 1998, just after digital satellite television. In the United States, the cutoff date for analogue TV was established in 2009, in Germany in 2008 and in Italy and UK in 2012.

Compression systems have also facilitated an increase in the transmission capacity of the networks, resulting in the multiplication of channels and storage, production, and distribution at decreasing costs, thus removing a major bottleneck from the whole TV industry chain. Since the cultural and social benefits that have historically been found in the broadcasting activity, free or low cost access to the spectrum has been granted to the broadcasters.

Digital competition has also revitalized the electronics market through the sale of digital receivers, set-top-boxes, televisions HD ready, as well as the 3D TVs or connected TVs.

Furthermore, as regards consumption habits, traditional live viewing is slowly declining everywhere while time-shifted and nonbroadcast viewing activities (such as Video on demand services or streaming video) are rising, through services delivered over the Internet, such as Netflix, Amazon Prime Video, Hulu, iQIYI, Youku, Ditto TV (now absorbed by Zee5), Now TV, with different percentages of subscription within the European countries and the USA (Ofcom 2017).

Resources and Business Models: Advertising, Public Funds, and Subscriptions

The television industry can be divided into three main activities, corresponding to three different economic functions. These are the programs' production, the organization of television programs in a schedule, and signal distribution in the territory (Owen and Wildman 1992). The signal distribution is undertaken by the presence of economic agents who make available to broadcasters the transmission equipment (carriers or network providers). Each distribution channel – operating through analog or digital terrestrial network, cable, satellite – involves different players (manufacturers, device producers, multiple-system operators, regulatory authorities). If the television service has controlled access (as for instance, pay-TV), packagers and pay-TV service providers will also be involved in some economic activities, such as customer relationships or channels bundling.

The cultural industries of most European and other countries have, historically, focused political attention and industrial policies on the scheduling and distribution aspects, as broadcasting systems were generally born as state-owned ones, while the US cultural industry gave centrality to the productive function and to advertising-based, privately owned, broadcasting models. One fundamental component of the television ecosystem is in fact the content, whose characteristics are important to determine the audience a broadcaster or a service provider wants to achieve. The production function can be

concentrated within the same broadcasters, either directly or through in-house production unites/subsidiaries, or it may result from independent firms (producers). In order to qualify as an “independent producer,” in Europe a production company must be a company (or other business entity) which is independent of broadcasters. The historical origins of European Union policy on self-sufficient audiovisual production and TV distribution found a cornerstone with the already mentioned “Television without Frontiers Directive.” Similar objectives can be found also in some American audiovisual policies, such as the “Prime Time Access Rule” (PTAR) and the “Financial Interest and Syndication Rules” (also known as “Fin-Syn”).

As regards the economic functions, the central activity of the television industry is the exchange of “television communication,” supplied by broadcasting networks and requested by viewers. The fundamental economic agents in the television ecosystem are therefore the television companies (“broadcasters”), who organize daily, weekly, and annual schedules.

This demand and supply of television communication is only exceptionally regulated by the price. In fact, from an economic point of view, the television product is an “information good” (Shapiro and Varian 1998), which can be reproduced and distributed somewhat inexpensively. In the case of free-to-air television, be it state-owned or private, the good offered is a classic “public good.” It is immaterial, it is not destroyed when consumed, and it is not divisible.

Its cost of production is not dependent on the number of people who will use it, that is, who will watch the program. However, the cost of production may affect the number of people who might want to look at the program (the most expensive productions will probably attract the larger audiences), but the cost will be the same, whether the program is seen or not. As “information goods,” they are subject to economies of scale and scope, resulting from the high fixed costs of production of the first copy (“sunk costs”). The marginal cost of this product is equivalent to zero, since a viewer added to the program will not alter in any way the production costs to be incurred. Moreover, the

fact that a person is watching the program does not diminish the ability of another person to see it. Since it is evident that no private operator would be interested in producing such a collective good as “television communication,” unable to achieve earnings from the end user (the viewer), another market intersects with the demand and supply just described, permitting a return on investments: the advertising market.

Advertising

A second product generated by the television industry is, therefore, the “commercial,” requested by companies that produce goods and services to be advertised. The viewer is characterized in this case as a receiver of advertisements, but also as a “product,” offered by the broadcaster to its clients, such as the companies wishing to advertise on its TV channels. The price is the instrument that regulates this market, and it is influenced by variables that are related to the economic cycle, the market structure, and by regulation at national or supranational level (such as the European level). Different information about the viewers (age, gender, jobs, buying habits, and tastes), different kinds of advertising spaces (commercial breaks, sponsorship, product placement, etc.), and types of television programs (sport, news, current affairs, cartoon, sit-coms, TV serials, soaps, TV movies, reality, etc.) influence the value and price of each advertisement sold.

The television ecosystem is thus composed also by advertising agencies and companies that measure television ratings.

Within the EU, the AVMSD set a broad framework concerning some general rules applicable to all forms of commercial communications for audiovisual media services, both linear or non-linear, thus influencing the way broadcasters may collect their principal resource. First of all, all forms of audiovisual commercial communications for cigarettes and other tobacco products as well as audiovisual commercial communication for medicinal products and medical treatment available only on prescription are prohibited, and audiovisual commercial communications for alcoholic beverages shall not be aimed specifically at minors and shall not encourage

immoderate consumption. Then, more in particular, all audiovisual commercial communications shall be limited both in contents and in time; they shall be readily recognizable as such, distinguishable from editorial content (by optical and/or acoustic and/or spatial means) and subliminal techniques are prohibited all over the EU. The forms of advertising which are regulated include teleshopping, sponsorship, and product placement. Sponsorship includes any contribution made by public or private undertakings or natural persons not engaged in providing audiovisual media services or in the production of audiovisual works, to the financing of audiovisual media services or programs with a view to promoting their name, trademark, image, activities, or products. News and current affairs programs shall not be sponsored and also stricter rules may apply during documentaries and religious and children's programs. Product placement is a form of commercial where there is no payment but only the provision of certain goods or services free of charge, with a view to their inclusion in a program, and it is admissible in cinematographic works, films, and series made for audiovisual media services, sports, and light entertainment programs, with an exemption for children's programs.

Public Funded Models

However, advertising-based TV is not the only economic model in the television industry (Picard 2002). In some countries, and especially for state-owned public service broadcasters, a television license (or a broadcast receiving license) is required of the viewers for the reception of the TV service or the possession of a television set. This form of funding is typical of European countries (Josephine 2015), where Public Service Media (PSM) operate according to some national and supranational laws. For instance, in the UK, the British Broadcasting Corporation, established in 1922, has been broadcasting TV since 1936 and the 1954 Television Act established commercial television; in Italy, RAI, Radiotelevisione italiana, began a regular state-owned television service in 1954; in 1956, TVE, Televisión Española, started regular broadcasting in Spain. In 1967 the US Congress created the Public Broadcasting System,

a noncommercial, public television network, funded, however, by congressional appropriations, viewer donations, and private corporate underwriters. During last years, many PSM objectives' revisions occurred, trying to adapt the infrastructure and the contents of historical PSM to multichannel and cross-platform scenarios. At the same time, all the mandates' revisions had to comply with the public service objectives identified in the "Protocol to the Amsterdam treaty on the system of public broadcasting in the Member States" (signed on November 10, 1997), which states that the system of public broadcasting (now PSM) in the Member States is directly related to the democratic, social, and cultural needs of each society and may help to preserve media pluralism. However, economic crisis as well as changing consumption habits both influenced the structure, the governance, and the business models of such services.

In Spain, for instance, advertising and public funded mixed models have been outmatched by public funds and private broadcasters/telecom operators taxation (Ley 7/2010). The same happened in France (this form of taxation has been approved by the Court of Justice of the European Union in 2013). In Finland, instead, direct taxes apply to the citizens, instead of a license, since 2012. In United Kingdom, finally, since April 2017, the independent authority OFCOM compassed the so-called BBC Trust in supervising the implementation of broadcasting legislation over the PSM.

As regards the public funded television business model, within the EU, article 107 of the Treaty on the Functioning of the European Union (TFEU) (ex Article 87 of Treaty establishing the European Community – TEC) provides that any aid granted by a Member State or through State resources in any form, which distorts or threatens to distort competition by favoring certain undertakings or the production of certain goods, shall be incompatible with the internal market (see entry ► "State Aids and Subsidies"). However, Article 106 specifies a number of circumstances (so-called "exemptions") in which the same state aid is acceptable, when some conditions apply, such as the service is clearly of general economic

interest by the EU county concerned, the undertaking in question must be explicitly entrusted by the EU country with the provision of that service, and the ban on state aid must obstruct the performance of the particular tasks assigned to the undertaking. Among these exemptions, some have direct or indirect influence on TV market. As for the direct influence, the public broadcasting service remit, in some circumstances and granting transparency in providing that service, may be included within the exemptions, according to the Amsterdam Protocol. In 2009 the EU Commission published a “Communication on the application of State aid rules to public service broadcasting,” following a 2001 first Communication and then three rounds of public consultations (2008 and 2009), providing again for a derogation for funding granted to broadcasting organizations for the fulfillment of the public service remit so long as it does not affect trading conditions and competition in the EU to an extent that would be contrary to EU interests.

As for the indirect influence, the Commission adopted a revised General Block Exemption Regulation (GBER) in May 2014, which includes aid schemes for audiovisual works. Article 54 of the Commission Regulation lists the specific compatibility criteria applicable to aid schemes for audiovisual works: particularly, the aid must support the script-writing, development, production, distribution, and promotion of audiovisual works, assuming that those products are cultural products as defined by each Member State with a selection and a predetermined list of cultural criteria. Aid may take the form of aid to the production, pre-production, and distribution of audiovisual works. Same Regulation defines also (Article 2) what is considered a “difficult audiovisual work,” which is “identified as such by Member States on the basis of pre-defined criteria when setting up schemes or granting the aid and may include films whose sole original version is in a language of a Member State with a limited territory, population or language area, short films, films by first-time and second-time directors, documentaries, or low budget or otherwise commercially difficult works.”

Finally, another indirect influence of the EU state aid framework on the TV market is the exemption concerning public investments on broadband (see entry on ► [“Public Investments: Broadband”](#)), as the always more convergent audiovisual world is strongly shifting from terrestrial free-to-air television systems or satellite technology to a broadband-driven audiovisual consumption.

Subscription-Based Models

Finally, TV revenues may also come from channel/bundles/content subscriptions, paid by the audience to access the content, both linearly and on demand. This form of revenue accounts for more than a half of the total revenues of the TV market worldwide, in 2016 (Ofcom [2017](#)). Pay-TV revenue is a well-established business model, especially in some country such as USA and Australia, followed by UK and Germany, while in other countries public funded or advertising-based models prevail.

Mostly, recently released films or TV series and sport events (so-called “premium contents”) and back-catalogue films are the most popular types of programs watched on subscription services. These services are in charge of traditional broadcasters, who differentiate business models reorganizing the offer through different platforms and revenue models, or are provided also by Over-the-Top operators. The widening of the TV market encompasses unquestionably the enrichment of the pay-TV offer, and the competition between actors in search for the richest targets (who may pay to access content) is growing, also thanks to the convergence between technologies and platforms.

Future Directions

During the last years, the TV market has been changing completely and viewers can now access TV content directly, on Internet platforms. At the same time, more traditional business models – advertising based or public funded – persist, offering to the audience an incredible amount of audiovisual contents, linear and on demand. Despite the convergent television-Internet-

telecommunications world that has been expected for decades, integration between platforms was initially very difficult. Relations between the TV ecosystem actors have been rough. Telecoms operators (see entry on ► [“Telecommunications”](#)) have tried to enter the television business many times, but it was not always easy and the first versions of Internet protocol television (IPTV) did not obtain their estimated success, in many countries. However, nowadays the so-called Quadruple players provide content across mobile, video, and broadband platforms (Ofcom [2017](#)). Content producers, distributors, and broadcasters, finally, compete today both with telecoms operators and with players coming from the web, such as the so-called Over-the-Top players (Google, Amazon, Netflix, Hulu, . . .), offering to the audience new forms of services and a huge amount of audiovisual contents.

Definition

Terrorism is the premeditated use, or threat of use, of extra-normal violence by non-state outside the context of legitimate warfare with the intention to coerce and intimidate an audience larger than the immediate victims in order to obtain political, economic, religious, or other social objectives through intimidation or fear.

Introduction

The *Global Terrorism Database (GTD)* defines terrorism as any action by a non-state actor (usually, a terrorist organization) outside the context of legitimate warfare with the intention to communicate (through the use of violence) with, coerce, or intimidate an audience larger than the immediate victims of a terrorist act, where this act is associated with achieving political, economic, religious, or other social objectives. Especially the terrorist attacks on New York and Washington, D.C., on September 11, 2001, have sparked a renewed interest in the economic analysis of terrorism and counterterrorism.

Given the persistence of terrorism (illustrated by Fig. 1 which uses data from the *GTD* to illustrate the global patterns of terrorism over the past decades), we want to provide an overview of the academic literature on the *economics of terrorism and counterterrorism*. The following contribution

is a condensed version of Schneider et al. (2014) and uses material from it. In the section “[Rational-Choice Theory and the Economic Analysis of Terrorism](#)” of this contribution, we discuss the role of rational-choice theory in the economic analysis of terrorism and counterterrorism. Here, we argue that simple cost-benefit models using rational-choice representations of terrorist behavior provide a well-founded model for the study of terrorism. In the section “[Terrorism and Counterterrorism in a Rational-Choice Framework](#),” we review the fundamental strategies of counterterrorism that follow from the rational-choice framework. We discuss the implications for the design of appropriate counterterrorism efforts and the empirical evidence assessing the effectiveness of these efforts. Here, we also take stock of the literature on the causes and consequences of terrorism. However, we also hint at the limitations associated with these simple cost-benefit models, which especially relate to the failure of accounting for collective action problems linked to the phenomenon of transnational terrorism and the dynamic interaction between terrorism and counterterrorism. Thus, in the section “[Interaction Between Terrorism and Counterterrorism](#),” we discuss some of the consequences that result from the reaction of terrorists and other economic agents to distinct counterterrorism measures. The section “[Conclusion and Future Research](#)” concludes by discussing which counterterrorism strategies

Terrorism, Fig. 1 Global terrorist activity, 1980–2007

may ultimately prove most helpful in the fight against terrorism.

Rational-Choice Theory and the Economic Analysis of Terrorism

Rational-choice models are the theoretical workhorse of most economic analyses of terrorism (e.g., Landes 1978; Sandler and Enders 2004; Caplan 2006; Freytag et al. 2011). In short, in a rational-choice approach, terrorists are considered rational actors who choose the optimal (utility-maximizing) level of violence by considering the costs, benefits, and opportunity costs of terrorism, where the utility from terrorism is usually associated with achieving certain (political) goals (Sandler and Enders 2004).

The existence of a calculus of (rational) terrorists allows for an economic analysis of terrorism. For one, it informs empirical studies on the *determinants of terrorism*. For another, it informs empirical studies on the *consequences of terrorism*. Figure 2 shows the relationship between rational-choice theory and the study of terrorism and counterterrorism.

Terrorists as Rational Actors

As argued by Krueger and Maleckova (2003), rational-choice models of terrorism can be considered as an extension of models that economically

analyze criminal behavior. Economic models of crime (Becker 1968) suggest that criminals are rational actors who maximize their utility subject to a calculus that involves the costs of criminal activity (e.g., from the risk of punishment), its benefits (e.g., the “wage” a crime pays), and its opportunity costs (e.g., foregone earnings from noncriminal activity). Analogous to this, rational-choice models of terrorism assume terrorists to be rational actors – behaving more or less like *homi economici* – that try to maximize their utility, given the benefits, (opportunity) costs, and economic constraints linked to these actions. While public perception tends to view terrorist behavior as “irrational,” psychological studies of terrorist behavior provide little evidence that terrorists routinely suffer from mental incapacities (for a review, see Victoroff (2005)). As a matter of fact, Caplan (2006) provides an extensive analysis of terrorist irrationality and comes to the conclusion that the sympathizers of terrorism and most active terrorists act more or less rational, so that “the rational choice model of terrorism is not that far from the truth [and] the Beckerian analysis of crime remains useful” (Caplan 2006, p. 101). This may even extend to the (rare) case of *suicide terrorism*. While Caplan (2006) argues that suicide terrorists indeed typically violate the rationality assumption of the rational-choice model and thus should be considered as outliers, Pape (2003) argues that even

Terrorism, Fig. 2 Rational-choice theory and the study of terrorism

suicide terrorism is the result of strategic-rational decision-making.

The Terrorists' Calculus

The Direct Costs Associated with Perpetrating Terrorism

The direct or material costs of terrorism are one element of the terrorists' calculus. Usually, these costs are associated with the operations of a terrorist organization, i.e., offensive and defensive activities. For instance, they accrue from acquiring financial resources, purchasing firearms and explosives, and establishing safe houses to evade government punishment.

The Benefits of Terrorism

Benefits of terrorism are connected with the tactical and strategic goals of terrorism. As argued by Schelling (1991), the short-run (tactical) goals of terrorism include *politico-economic destabilization* (to weaken their enemy, i.e., the state) and *media attention* (to communicate the terrorists' cause). Thus, achieving these tactical goals ought to provide the member of a terrorist group with benefits. The long-run goals of terrorist groups usually involve the wish to induce political, economic, religious, or social change, most prominently (for separatist terrorist groups) gaining independence and (for religious and left-wing or right-wing terrorist groups) changing a country's politico-economic system to have it coincide with religious doctrine or political ideology. These political objectives are discussed in more detail in Shughart (2006). Any success related to achieving these long-run goals (through government concessions, territorial gains, winning political influence, etc.) also ought to constitute a benefit from terrorist activity.

The Opportunity Costs of Terrorism

The opportunity costs of terrorism refer to the foregone utility associated with non-terrorist activity. Typically, this utility comes from material rewards (i.e., wages) linked to nonviolence, e.g., participation in the ordinary economic life. It can also be understood as a monetary equivalent (derived from economic activity) of the potential

political influence associated with terrorist activity. Such lines of reasoning are at the center of many contributions that try to economically model terrorist behavior (e.g., Sandler and Enders 2004; Freytag et al. 2011).

Terrorism and Counterterrorism in a Rational-Choice Framework

The identification of an economic calculus associated with terrorist behavior allows for *three fundamental strategies* to reduce terrorist activity. Ceteris paribus, the utility-maximizing level of terrorism (i.e., the observed level of violence) ought to be lower when (1) the costs of terrorism are increased, (2) the benefits of terrorism are reduced, or (3) the opportunity costs of terrorism are raised. We discuss these options below in more detail.

Raising the Costs of Terrorism

Any counterterrorism policy that aims at raising the material costs of terrorism (e.g., by raising the penalty for terrorist offenses, direct police or military efforts) ought to make it more difficult for terrorist groups to maintain their level of activity.

The prevailing counterterrorism strategy to raise the direct costs of terrorism is *punishment and deterrence*. This strategy involves the use of direct state action by the police, military forces, and intelligence agencies to capture active terrorists and their supporters, while also deterring potential recruits (due to long prison sentences, increased probability of being captured, etc.). Indeed, counterterrorism activities by the police and intelligence services (e.g., infiltration through the use of informers and undercover agents, observation, information gathering) have repeatedly weakened the operative capacity of terrorist organizations (for an overview, see Schneider et al. (2014)). Also, empirical evidence suggests that increased punishment for specific kinds of terrorist activity leads to fewer of these acts (e.g., for the case of skyjackings, see Landes (1978)). As for a more harsh direct counterterrorism strategy, efforts in the form of decapitation – i.e., the killing of terrorist leaders – have also been shown

to prove helpful against terrorist groups (e.g., Johnston 2012).

Reducing the Benefits of Terrorism

Previously, we have established that the benefits of terrorism are directly linked to the short-run and long-run objectives of terrorist organizations. In the short run, the benefits from terrorism arise from politico-economic destabilization and media attention, both of which help the terrorists to achieve their long-run sociopolitical objectives. Indeed, many empirical studies have established that terrorism tends to negatively affect political development (e.g., in the form of respect for human rights) and political stability (e.g., Dreher et al. 2010). There is also evidence that terrorism reduces economic activity, e.g., by depressing domestic and foreign investment or tourism (e.g., Crain and Crain 2006; for a review, see Sandler and Enders (2008)).

Counterterrorism efforts may be effective when they successfully deny terrorist groups media attention and increase a country's politico-economic resiliency to terrorism's destabilizing effects, which ultimately ought to mean that political concessions associated with the long-run goals of terrorist groups become less likely. This is because less media attention and less success in producing politico-economic damage are expected to negatively affect a terrorist organization's bargaining position vis-à-vis the government it opposes (Schneider et al. 2014).

One interesting strategy to increase politico-economic robustness is *decentralization*. Political decentralization ought to make it less likely that terrorism creates a political vacuum (e.g., when prominent political figures are assassinated) that cannot be filled by other actors or levels of government (Frey and Luechinger 2004). Economic decentralization is expected to have a similar effect on terrorism. It may include avoiding concentrating power within a company in the hands of few individuals (because these individuals are attractive targets for attacks), not concentrating a company in one large headquarters (particularly when this headquarter is located in an iconic building such as the World Trade Center), and using multiple (rather than monopolistic) suppliers to immunize

a company's supply chain against disruptions (Frey and Luechinger 2004). Indeed, Dreher and Fischer (2010) find that decentralization may reduce the likelihood of terrorism.

Other means to reduce the benefits of terrorism may include, e.g., the increased protection and fortification of prospective terrorist targets and denying the terrorists media attention by means of spreading disinformation (Schneider et al. 2014).

Influencing the Opportunity Costs of Terrorism

While raising the direct/material costs of terrorism usually involves manipulating related *facilitation factors* (e.g., by restricting access to firearms and explosives), influencing the opportunity costs of terrorism typically involves policies that try to ameliorate *grievances* that underlie social conflict.

Among the factors possibly involving grievances and thereby inciting terrorism that are analyzed in cross-national studies are (1) *poor socioeconomic conditions* (e.g., Freytag et al. 2011); (2) *unfavorable political and economic institutions* which, e.g., do not sufficiently protect civil liberties and do not enable politico-economic participation (e.g., Krueger and Maleckova 2003; Abadie 2006); (3) *demographic stress*, e.g., in the form of discrimination along ethno-religious lines (e.g., Piazza 2011); (4) trends in *globalization* that may generate resentment among the "globalization losers" and traditionalist who fear that the inflow of foreign ideas threatens their local culture or religion (Zimmermann 2011); and (5) *aggressive foreign policy behavior* – in the form of, e.g., military interventions, state sponsorship of terrorism, and overall politico-military dominance – which tends to coincide with more terrorist activity directed against the proponents of such policies (e.g., Pape 2003; Dreher and Gassebner 2008). Gassebner and Luechinger (2011) and Krieger and Meierrieks (2011) summarize the empirical literature on the causes of terrorism.

Ameliorating the aforementioned social conditions ought to reduce terrorism by swaying its opportunity costs in ways that make violence

a less attractive option. However, according to the reviews by Gassebner and Luechinger (2011) and Krieger and Meierrieks (2011), there is little consensus on the importance of specific social conditions in the emergence of terrorism. For instance, while some cross-country studies find that poor socioeconomic conditions predict terrorism (e.g., Freytag et al. 2011), other studies find that political variables are more important than economic ones (e.g., Krueger and Maleckova 2003; Abadie 2006). Thus, there seems to be no obvious “policy panacea” to fight terrorism by favorably affecting its opportunity costs. What is more, influencing the social conditions that underlie terrorist conflict in favorable ways tends to be a long-run and complex counterterrorism option, particularly in comparison to options that try to affect the direct costs of terrorism.

The Case of Transnational Terrorism

Counterterrorism efforts may be further complicated when terrorism becomes transnational. By definition, this is the case when more than one country is involved in a terrorist conflict. For instance, terrorism may internationalize when terrorist groups use foreign territory to challenge another government (e.g., the use of Syria, Jordan, Lebanon, Tunisia, and other Middle Eastern countries as bases of operation for Palestinian terrorist activity against Israel in the 1970s and 1980s).

International counterterrorism strategies still aim at influencing the (opportunity) costs and benefits of terrorism in ways that make (internationalized) terrorism less attractive. However, it is precisely their transnational nature that makes these strategies even more difficult to implement. Sandler (2005) shows that internationalized terrorism usually involves *collective action failures* for countries attacked by transnational terrorist groups. While governments are able to choose an optimal counterterrorism strategy in the fight against domestic terrorism, counterterrorism against transnational terrorism may involve externalities. For instance, it may be attractive for some – often weak – states to tolerate the activities of terrorist organizations within their borders in exchange for no direct harm at the expense of other nations (*paid riding*).

Also, national governments may be tempted to overstress defensive counterterrorism measures to deter terrorist attacks, which may merely result in a relocation of terrorist attacks against the respective nation’s citizens (e.g., there were more anti-US attacks in the Middle East and Africa after 9/11 had led to stronger counterterrorism efforts within the United States). Alternatively, as suggested by Sandler (2005), countries may try to place the burden of offensive counterterrorism measures (e.g., preemptive strikes) onto the prime target of transnational terrorism, thereby benefitting from the reduction of terrorism without paying for it (*free riding*). More generally, defensive policies can be regarded as largely private goods, so that the benefits of security provision are mostly internalized by the investors, while proactive policies show the characteristics of public goods (Sandler and Siqueira 2006). Consequently, this may lead to an oversupply of defensive and an undersupply of proactive measures (Sandler and Siqueira 2006).

Collective action problems (e.g., free and paid riding, benefits of noncompliance) have so far undermined many measures directed against terrorism at an international level. For instance, Cauley and Im (1988) find that the introduction of a United Nation’s convention on preventing crime against diplomatic personnel did not help to reduce terrorism directed against diplomats. Similar problems arise when international counterterrorism efforts aim at curtailing terrorism by means of military actions (e.g., the US air strikes against Libya in 1988 in retaliation of alleged Libyan support for anti-US terrorism, which in turn led Libya to sponsor anti-American terrorism) and the use of economic and/or military aid (Schneider et al. 2014).

Interaction Between Terrorism and Counterterrorism

Previously, we have argued that rational-choice theory helps to understand how terrorism develops and how it can be countered through three fundamental strategies that aim at influencing the (opportunity) costs and benefits of terrorism in ways that make terrorism less attractive. One

shortcoming of this approach, however, is its *static* nature. In reality, terrorism and counterterrorism tend to interact. In this section, we therefore give a brief – nontechnical – summary of typical interactions between terrorism and counterterrorism. Some of these points are also discussed in Kydd and Walter (2002) and Findley and Young (2012).

Adaption, Innovation, and Substitution

Terrorist organizations may be able to adapt to specific counterterrorism measures by means of innovation and/or substitution. The former may include, e.g., the use of more advanced terrorist “technology” to attack (e.g., the use of more powerful weapons) or organizational innovation as a hierarchical group develops into a looser terrorist network with a cell structure. The latter may involve, e.g., choosing new targets that are less protected by counterterrorism measures. Arguably, substitution effects are standard elements of economic models, so that it is not surprising that such effects also matter to the economic study of terrorism and counterterrorism (Enders and Sandler 2004). As a consequence, the evidence suggests that some counterterrorism measures may merely change the face of terrorism (e.g., new attack methods, new targets) but not affect the overall level of terrorist violence (Schneider et al. 2014).

Provocation and Escalation

Findley and Young (2012) argue that terrorist groups may use terrorism to provoke a harsh, disproportionate response by the government (e.g., by means of excessive police force), which in turn is expected to fuel radicalization and social polarization, meaning that provocation and excessive counterterrorism measures by the state may easily result in cycles of violence. Indeed, it seems to be in the natural interest of terrorist groups to muster additional support by letting any social conflict escalate, given that broader conflicts (e.g., civil wars) make it easier for them to pursue and implement their agendas (Findley and Young 2012).

Spoiling the Peace

As a specific reaction to government concessions, terrorist groups may try to spoil the peace. For

instance, terrorist groups may have economic incentives (e.g., gains from illegal activity) associated with conflict and thereby oppose peace. Thus, it may be in the natural interest of extremist factions to sabotage the peace (Kydd and Walter 2002). Crucially, such sabotage may result in – as it is in the interest of the attacking groups – an end of negotiations and concessions and, instead, provoke more violent counterterrorism measures. Kydd and Walter (2002) argue that spoiling the peace – as a reaction to benevolent policy measures such as concessions – may be particularly effective when mistrust and weakness among the more moderate negotiator on the sides of the terrorists and the state abound.

Organizational Evolution

We have already discussed above that terrorist groups may innovate in the face of counterterrorism by changing their internal organization (e.g., moving from a hierarchical to a cell structure). However, counterterrorism may also result in changing the overall politico-military orientation of a terrorist group. The nature of these changes depends on the offered incentives and the effectiveness of counterterrorism. For one, positive incentives and relative counterterrorism effectiveness may lead to a situation where a group gives up its armed struggle, evolving into a political party that tries to foster change nonviolently. One example is the Colombian *Movimiento 19 de Abril*. For another, however, negative incentives and/or relative counterterrorism ineffectiveness may lead to an escalation of conflict, so that terrorist campaigns may evolve into full-scale insurgencies (Findley and Young 2012). As another possibility, perhaps in frustration over the inability to achieve certain political goals due to counterterrorism, terrorist groups may become increasingly interested in purely financial gains, evolving into criminal groups.

Conclusion and Future Research

In this entry, we provided an overview of theoretical and empirical studies on the economic

analysis of terrorism and counterterrorism. We argued that rational-choice models of terrorist behavior provide a good starting point for such analyses. Here, simple cost-benefit models that follow from rational-choice approaches imply that terrorism can be fought by affecting the terrorists' calculus which involves the (opportunity) costs and benefits of terrorism. We discussed a number of specific counterterrorism strategies (e.g., direct police or military action, decentralization) that follow from such models. One factor that complicates these models – and the strategies derived from them – are collective action problems that arise when terrorism becomes transnational (the most infamous example being the 9/11 attacks). Another complicating factor associated with these simple cost-benefit models is that they are usually static and thus miss the dynamic nature of the terrorism-counterterrorism relationship. We (non-exhaustively) discussed a number of reactions of terrorist groups to specific counterterrorism strategies (e.g., the use of innovative modes of attack in the light of target-hardening efforts). These interactions show that the relationship between terrorism and counterterrorism tends to be more complex than simple cost-benefit models – even though they provide a good starting point for any economic analysis of terrorism – can capture.

Considering the most effective counterterrorism strategy, our entry suggests the following: (1) Strategies that involve influencing the benefits of terrorism (e.g., target protection) usually do not stop terrorism but lead to adaption (new targets, new methods, etc.). (2) Raising the direct/material costs of active terrorists (e.g., through military means) may prove effective in the short run. Indeed, many terrorist groups have been negatively affected by military pressure. However, such efforts may easily backfire, creating (potentially large) unintended consequences. Here, (relative) counterterrorism ineffectiveness may contribute to the emergence of powerful insurgencies or crime networks, i.e., to the evolution rather than decline of terrorist groups. For instance, the French counterterrorism efforts during the Battle of Algiers of 1957 against the Algerian *Front de Libération*

Nationale (FLN) were a military success but – due to use of torture and other harsh counterterrorism measures – led to the international political isolation of France and growing (domestic and international) support for the *FLN*, while also triggering a political crises in France. (3) Strategies that aim at raising the (opportunity) costs of terrorism by “winning the hearts and minds” of would-be terrorists, potential terrorism supporters, and possibly even active terrorists seem to be more effective in the long run. For instance, terrorist groups may disappear due to a loss of legitimacy – e.g., as popular support for terrorism dwindles due to higher terrorism opportunity costs in the face of benevolent counterterrorism strategies – or evolve into political parties when political participation opportunities open up.

Clearly, the effectiveness of these strategies is very much context-dependent. Counterterrorism strategies that worked well against terrorism in the twentieth century (which usually had domestic goals, was hierarchically structured, and attacked primarily military targets) may prove unsuccessful against the *Al-Qaeda*-styled terrorism of the twenty-first century (which has transnational goals, is organized as a network, and also attacks civilian targets). This provides many avenues for future research. For instance, this research may try to evaluate the appropriateness of counterterrorism strategies vis-à-vis, e.g., the goals of terrorist organizations (to assess which kinds of concessions can be made), the implementation costs of specific policies (to examine their cost-efficiency), the international perspective (to factor in collective action problems), the overall level of popular support for terrorism, and the organizational structure and politico-military strategy of a terrorist group. These factors have been largely disregarded in the theoretical and empirical literature on terrorism and counterterrorism.

Abstract

Third-party litigation funding allows the transfer by the plaintiff of his/her legal costs to a financial company whose sole aim is to make profit. TPLF have an impact on access to justice but also on conflict resolution and finally on social well-being. The aim is to show how law and economics scholars invest this new field of the conflict literature and study the role of this new actor in the litigation.

Definition

Third-party litigation funding (TPLF) is a financial activity that consists in an investment company specialized in the financing of litigation agreeing to cover all or part of the trial costs of a litigant, in exchange for a portion of the damages paid if the case is won. The remuneration of the funding third party can be a multiple of the initial investment (1.5–6 times), a percentage of the award obtained in a judgment or out-of-court settlement (20–40%, sometimes 50%), or a combination of both (Veljanovski 2012). The funds used are provided by wealthy individuals, families or institutions, insurance companies, or hedge funds (de Silguy 2013; Veljanovski 2012). The return/risk ratios can reach very high levels, up to 200% of the amounts invested (McLaughlin 2007), sometimes more (Abrams and Chen 2013). There are several types of TPLF: interest-bearing loans intended to provide replacement income to victims of bodily injuries or discriminatory practices (consumer legal funding), loans to firms of lawyers in a contingent fees system, and investment in commercial litigation in exchange for a percentage of the damages (Faure and De Mot 2012).

Introduction

Historically, TPLF first appeared in the Middle Ages, but the prohibition of “maintenance” and “champerty” in the United States prevented it developing (Lyon 2010). It reappeared in Australia at the beginning of the 1990s, before

spreading to other common law countries. Its development in countries with a civil law tradition came later and was more modest, with the exception of Germany and, to a lesser extent, Austria and Switzerland. TPLF concerns both litigation before the courts and arbitration procedures (in international trade in particular).

There are many arguments in favor of developing TPLF. The most immediate advantage is the removal of the financial barrier to the plaintiff’s access to justice (Jackson 2009). Other arguments relate to the easier access to third-party capital (Daughety and Reinganum 2014); better allocation of funds for companies, which can invest in their business instead of devoting funds to their defense (Rubin 2011; Veljanovski 2012); and a better division of the risks (De Mompurgo 2011) between a risk-averse plaintiff and a neutral third-party funder who can pool the risks in a portfolio of claims not correlated with each other (Rubin 2011).

The economic analysis of TPLF means studying the impact of having litigation funded by a third party on the one hand, litigants’ access to justice on the other, the method of resolving disputes, and finally the impact on social well-being.

TPLF and Access to Justice

From a theoretical point of view, TPLF is based on the idea that the right to sue is exchangeable according to the Coase theorem: by injecting funds into the case, the funder purchases the right to receive all or part of the recovery. By doing so, the funder facilitates access to justice by removing the financial constraint on the plaintiff, as do other schemes (legal aid, legal expenses insurance, contingent fees), but only in lawsuits where the stakes are high (De Fontmichel 2012) and mainly, in Europe, in the field of international arbitration. In a model inspired by Katz (1990), Deffains and Desrieux (2014) have demonstrated, however, that access to justice is not guaranteed even for meritorious claims. Indeed, the third-party funder will invest in a case if, first of all, he considers that it is sufficiently profitable once all the transaction costs have been taken into account (obligation to sign two contracts, one between the lawyer and the client and another between the third part funder and the client, cost

of negotiating the percentage of the damages or the interest rate, costs of obtaining experts' opinions, dispute solving costs, etc.) and, secondly, if it is more profitable than alternative investments. They also show that where there is asymmetry in the information on the real quality of the case, TPLF can encourage plaintiffs bringing frivolous lawsuits to bring more actions than in a no-win, no-fee arrangement or if they are self-financing. This outcome is due to the fact that the equilibrium settlement amount is lower with TPLF and therefore the likelihood of reaching an arrangement with the defendant is higher.

As well as facilitating access to justice, TPLF guarantees a better defense of plaintiffs' interests. Indeed, TPLF will orient the plaintiff toward better lawyers, whom he will be also be able to better control (Schanzenbach and Dana 2009). However, a problem of agency can arise between the third-party funder and the lawyer. Demougin and Maultzsch (2014) nevertheless show that it is possible to arrive at a combination of third-party funding and a no-win, no-fee arrangement that can overcome both these agency issues and the access to justice difficulties of potential plaintiffs with "deserving" claims.

Impact of TPLF on Methods of Conflict Resolution

TPLF has an impact on the method of conflict resolution because it increases the plaintiff's bargaining power: with the benefit of substantial financial resources thanks to the support of the third-party funder, his threat of taking legal action gains in credibility (De Mompurgo 2011). TPLF is therefore thought to be a way of enabling small- and medium-sized enterprises to fight large international disputes on an equal footing (De Fontmichel 2012).

Furthermore, TPLF breaks the monopsony power of the defendant: the third-party funder, along with the defendant who wants to come to an arrangement, can be considered as buyers of the plaintiff's right to sue (Hylton 2014). With the resources that he devotes to raising the value of the right he has thus acquired, the third-party funder enables the plaintiff to obtain a better award (Avraham and Wickelgren 2014) and

ensures a higher likelihood of judgments being enforced (De Fontmichel 2012).

The credibility of the plaintiff's threat of legal action is also reinforced by the credibility of the signal concerning the quality of the case, due to the in-depth investigations (defendant's solvency, chances of success, quality of the lawyers) carried out by the third-party funder in order to minimize his risks (Faure and De Mot 2012). For Avraham and Wickelgren (2014), it is in the third-party funder's interests to send a clear signal to the defendant and to the judge about the quality of the case he is funding, via the interest rate applied to the plaintiff.

Ultimately, few claims will be selected (those with more than a 70% likelihood of being won, according to Veljanovski 2012), so that the third-party funder's actual risk is zero. Daughety and Reinganum (2014) confirm this in the case of TPLF where the third party provides the plaintiff with funds to cover his day-to-day expenses. The authors have produced a signal model where the plaintiff has private information on the real value of his case that determines its type. They show that the optimal interest rate, understood as that which maximizes the joint payment of the plaintiff and the funder, always leads to an out-of-court settlement of the dispute, whatever the type of plaintiff. Kirstein and Rickman (2004) arrive at the same result in a configuration where there is no information asymmetry but only diverging estimates by the parties of the plaintiff's chances of winning the court case.

TPLF and the Improvement of Social Well-Being

By facilitating access to justice, TPLF generates positive externalities that tend to increase social well-being. Thus, Hylton (2012) explains that if socially desirable legal action is not taken because it is not cost-effective, then TPLF is socially desirable because the transfer of costs that it allows makes legal action cost-effective for the plaintiff from a private point of view. This implies that there are an optimum number of litigation cases. Any analysis of the social desirability of TPLF should therefore start by determining whether the number of litigation

proceedings brought is lower or higher than the socially optimal number.

Other positive external effects are also discussed in the literature. For example, TPLF is said to increase competition between lawyers (Veljanovski 2012; Costargent 2012) but also between large law firms on the one hand and third-party funders on the other (De Fontmichel 2012). Finally, according to De Morpurgo (2011), by facilitating access to justice, TPLF is said to increase equality of litigants before the law, which would therefore have the consequence of increasing the usefulness of all individuals with a concern for justice and therefore also social well-being.

In addition to these positive external effects, there are also negative external effects, which render the conclusions on the social desirability of TPLF theoretically undetermined. It is quite possible, for example, that the drop in the number of expected damages cases will not last. Hylton (2014) is interested not in existing, matured claims but in potential future, unmatured claims. The sale of *ex ante* rights is a complex issue because inefficient rights transfers can lead to an increase in the number of damages cases for potential victims. It all depends on the third party's intentions. If what he wants to achieve is the payment of damages, his interests are in line with those of the potential victim, and social well-being is therefore potentially increased. However, if his aim is to avoid proceedings by purchasing his right to reparation from the victim (interests in line with those of the defendant), then there will be fewer precautions taken and therefore an increase in the frequency of damages cases.

Rubin (2011), however, worries about the defendant's situation. The defendant's participation in the conflict is determined by the plaintiff's decision to take legal action. The American rule on the allocation of litigation costs creates an externality for the defendant, who necessarily has to bear his litigation costs. In the case of TPLF, in particular in commercial lawsuits, those litigation costs are usually high. Any measure facilitating plaintiffs' access to justice must take account of the costs borne by the opposing party. In the end, better access to justice is socially desirable if the expected benefits are higher than

all the litigation costs, as for it the damages paid are a simple transfer.

Conclusion

The question of the socially desirable nature of TPLF runs through all the articles on this form of funding access to justice. The fears most often expressed concern the risk of encouraging socially undesirable litigation; economic analysis of conflicts shows that this appears to be unfounded due to third-party funders' very strict selection of the cases they take on. Furthermore, there can be other positive effects, in particular in terms of damage prevention. However, these are counterbalanced by the risk of congestion of the courts, the development of a compensation culture rather than a culture of recognizing rights and the risks that the intervention of a third party can bring to bear on the lawyer-client relationship.

It has to be admitted that the theoretical conclusions do not provide a definitive answer to the question of the social desirability of this type of funding. Empirical studies could in this case provide some assistance with decision-making. There is only one empirical article on the subject, concerning Australia. Abrams and Chen (2013) demonstrate that third-party funding of litigation increases the frequency of legal action being brought and the number of court cases. They ascertain in particular that in the Australian States where third-party litigation funding is common, the courts are very congested, the number of cases is completed, and the elucidation rate are lower, which also has consequences for the courts' spending. And yet, the authors explain that these effects may be temporary and the conclusions in terms of social well-being ambiguous (increase in the rate of out-of-court settlements, faster recognition of rights, clarification of the law). These conclusions cannot, however, be generalized to all countries.

Titling Systems

Benito Arruñada

Pompeu Fabra University and BGSE, Barcelona, Spain

Definition

Titling systems are the institutions used to enforce property rights as rights in rem and reduce the cost of transacting on them. To be effective in non-local markets, they require a registry, which produces information on claims or rights, thus allowing the judge to verify them, establish their relative priority, and solve conflicts between claimholders by adjudicating rights in rem and in personam to them. Since the judge relies on register evidence, access to registers also allows contractual parties to reduce their information asymmetry before transacting.

Introduction: The Tradeoff between Property Enforcement and Transaction Costs

Rights to land and many other assets can be enforced as property rights, *iura in rem*, claimable against the asset itself and therefore valid against all persons, *erga omnes*. These property rights are said to “run with the land,” meaning that they

survive unaltered through all kinds of transactions, and transformations dealing with other rights on the same parcel of land or on a neighboring parcel. For example, the mortgagee keeps the same claim on the land even after the mortgagor sells it. Property rights oblige all people: the new owner who has purchased the land is obliged to respect both the mortgage and, in particular, the right to foreclose if the guaranteed debt is not paid. Enforcement of a property right is independent of who holds other rights on the same asset. Alternatively, rights on assets can be contract rights, enforceable against a specific person, *inter partes*. To clarify the difference between property and contract rights, consider what happens in the case of a lease of land, this being a right that in many jurisdictions may be structured as either a contract or a property right. Assume that the land is sold during the life of the lease. If the lease is a contract right, the lessee loses the right of occupation and gains instead a contract right against the lessor. However, if the lease is a property right, the lessee keeps the right of occupation. It is then the land purchaser who may have a contract right against the seller, if the sale was made free of leases. The buyer is subrogated into the seller's position. There is no change to the lease, which has run with the land from the seller to the buyer and survives intact after the sale.

When the law enforces a right as a right in rem, consent of the right holder is required for the right to be affected, that is, damaged, in any way. This requirement of consent – either real or constructive – provides precious enforcement benefits for rights on durable and immovable assets. The enforcement of contract rights, on the other hand, depends on the availability, resources, and legal status of persons, who are mobile and may become unavailable, or judgment proof when obliged to pay. For durable assets, a property right is therefore much more valuable than a contract right having the same content – that is, when the only difference between them is that the latter lacks in rem enforceability.

These enforcement benefits come at a cost, however. When multiple rights exist on an asset, transactions do not convey property rights with the promised in rem extent until all affected right

holders have consented. In other words, to produce perfect property – that is, in rem – rights, some kind of explicit or implicit contracting has to take place between the transactors and each of the affected right holders, in order for the latter to give their consent. Many institutions in the field of property law are designed to make these “contracts” with affected right holders possible. Consent can be given explicitly, by private agreement, declaring to a register or in court proceedings, as well as implicitly, simply by the passing of time. Consent can also be produced at the moment the transaction takes place. Consequently, the rights resulting from the transaction will be free of uncertainty as to who the true legal right holder is and as to their precise nature. Alternatively, consent can be postponed, and the transaction then produces rights which are burdened with the survival of any property rights whose right holders have not yet consented.

In any case, without the consent of affected right holders, transactions produce a mix of property and contract rights: property – that is, in rem – effects to the extent that is compatible with the surviving property rights held by others and contract rights for the difference. The proportion of property and contract rights in the mix varies with the kind of conflicting right. In the extreme case of a fraudulent conveyance, the grantee gets only a contract right against the grantor, who is not the true legal owner. More generally, any intended property right is in fact partially contractual if an affected right holder keeps a contradictory or concurrent right against it.

Property rights thus face a trade-off with positive and negative effects (Arruñada 2012). On the one hand, they facilitate specialization by ensuring enforcement, given that right holders' consent is required to affect them. However, for the same reason, their survival after conveyance of the asset or any other transformation of rights requires costly institutions (mainly, property registers) in order to organize the process of searching, bargaining, and contracting for consent. In particular, the possibility of hidden property rights increases the information asymmetry between the conveying parties: the seller knows better

than the acquirer about hidden property rights. More generally, the need to know which conflicting property rights exist and who their holders are, and bargaining with such right holders to obtain their consent and contracting or somehow formalizing an agreement with them, all increase the costs of transforming and conveying rights. This may in turn hamper investment, trade, and specialization.

Private Titling: Privacy of Claims as the Starting Point

Under the Roman law tradition of private conveyance that was dominant in Europe until the nineteenth century, private contracts on land had in rem effects on third parties, even if they were kept secret. The baseline legal principle was that no one could deliver what they did not have (*nemo dat quod non habet*), which was closely related to the principle “first in time, first in right.” So, in a double sale of land, in which an owner O sells first to buyer B_1 and later to B_2 , the land belongs to B_1 because, when O sold to B_2 , O was not the owner. In cases of conflict, the judge will allocate property and contract rights between both claimants (B_1 and B_2) – that is, will “establish title” – on the basis of evidence on possession and past transactions, whether or not these transactions had remained hidden.

This potential enforcement of adverse hidden rights made gathering of all relevant consents close to impossible, hindering trade, and specialization. Most transactions in land therefore gave rise, totally or partially, to contract rights, and the enforcement advantage of property rights remained unfulfilled, especially with respect to abstract rights, such as mortgages. These difficulties are clear in the functioning of the two sources of evidence traditionally used to establish title under privacy: possession and the chain of title deeds.

First, the use of possession – that is, as a first approximation, the fact of controlling the asset – as the basis for establishing property rights is a poor solution for durable assets, because for such assets it is often valuable to define multiple

rights, at least separating ownership and possession. However, relying on possession to establish ownership makes it possible for possessors to fraudulently use their position to acquire ownership for themselves or to convey owners’ rights to third parties. In such cases, owners will often end up holding a mere contract right, an in personam right, against the possessor committing the fraud. Understandably, under such conditions, owners will be reluctant to cede possession impersonally, for fear of losing their property. Similarly, credit will involve contractual, personal guarantees provided either by the debtor or by the lender. This is because the only way of providing some type of in rem guarantee to the lender is by transferring ownership or possession to him, thus leaving the debtor subject to the lender’s moral hazard and safeguarded only by the lender’s contractual guarantee, which is weaker and costly to produce.

Second, some of the problems posed by possession are solved by embodying abstract rights, such as ownership and liens, and even complementary consents in the conveying contracts, which then form a series or “chain” of title documents or deeds (“chain of deeds,” for brevity) that is based on what can be labeled “documentary formalization.” This evidencing of rights with the chain of deeds facilitates some degree of separation of ownership and control because it is the content and possession of deeds that provide evidence of ownership. Therefore, title experts can examine the history of transactions going back to a “root of title,” which is proof of ownership in itself – either because it is an original grant from the state or, more often, because of the time that has lapsed beyond the period of prescription or the statute of limitations. However, relying on the chain of deeds also creates problems. Above all, new possibilities for error and fraudulent conveyance appear, giving rise to multiple chains of title, which leave acquirers with contract rights against the fraudulent grantor and the professionals involved in the transaction. Moreover, titles are less effective than possession in reducing the asymmetry of acquirers, as possession is observable but adverse chains of title remain hidden to the acquirer. Furthermore, acquirers remain fully unprotected against any hidden charges that are

not voluntarily contracted, such as judgment and property tax liens. Similarly, the chain of deeds also serves to enforce a security, by pledging the deeds with the lender. But this solution is also defective, as it subjects the debtor to the lender's moral hazards (the lender could impede a sale or even fraudulently sell) and causes switching costs that make mortgage subrogation difficult.

Despite these difficulties, transactions on unregistered land in England heavily relied on the chain of deeds up until the last decades of the twentieth century. Typically, ownership was proved by possession and the whole series of deeds, which was often kept by the owner's solicitor. And mortgages were formalized by pledging the deeds with the lender. Likewise, during the *ancien régime* notaries public in most civil law countries played a similar role to that of English solicitors, with the advantage that each notary office kept an archive with the original of all the titles it notarized. This gave notaries privileged access to information on the transactions that each office had authorized. However, they did not provide an effective substitute for mortgage registries, mainly because notaries' information about individual debtors was incomplete. These cases therefore illustrate a constant feature of privacy regimes: to contain fraud, private conveyancing services provided by solicitors and notaries tend to develop into professional monopolies.

Whatever the system of documentary formalization for private conveyance contracts, conveying parties will always try to contract relying on the evidence that will eventually be used by the judge to establish title. Under privacy, however, given that courts may enforce in rem rights that have remained hidden, examination of title quality is based on potentially incomplete evidence. Therefore, removal of title defects and contradictions, as well as any adjustments to the terms of the private contract, are informed only by the limited and hard-to-verify publicity provided by possession and by documentary formalization and are motivated by the risk the grantor faces when giving title warranties on a defective title. But acquirers have limited possibilities of knowing what they are buying. They, in fact, acquire residual property in rem rights plus a contract in

personam right against the grantor for the difference between the in rem property rights effectively granted and what the grantor had promised to deliver.

Understandably, legal systems try to counterbalance this chronic incompleteness of property rights in their in rem dimension under a privacy regime by adopting private and public means to strengthen contract in personam rights, such as granting formal guarantees, expanding the scope of criminal sanctions, and even relying on bonding and slavery. Moreover, legal systems also provide specialized judicial procedures capable of purging title – that is, establishing which rights in rem are alive and who holds them – thus producing a public reallocation of rights that should be useful at least to solve the most complex and valuable cases.

Ceremonial Publicity and Recordation of Deeds

Whatever the palliatives applied, the costs of contracting true property – that is, in rem – rights under a regime of pure privacy are so high that modern systems of property law have abandoned privacy in an effort to lower them. At a minimum, the law induces or requires the independent publicity of contracts, which makes them verifiable, as a prerequisite for them to attain in rem effects – that is, to convey property rights and not mere contract rights. If they keep their claims private, right holders lose or risk losing in rem effects. Private contracts may create obligations among the conveying parties but do not bind third parties: all other right holders and, especially, potential future buyers and lenders. Independent publicity therefore facilitates finding out which property rights are alive and which will be affected, thus making it possible to gather consents, purge titles, and reduce information asymmetries between the conveying parties. At a maximum, in addition to requiring publicity of contracts, the law also requires a complete purge of conflicting claims for each transaction. Because this purge is supervised by a public registrar acting in a quasi-judicial capacity, the registry does

not merely provide publicity of claims but also defines and publicizes rights.

Specific laws therefore vary substantially with respect to how and when any contradiction with other property rights must be purged by obtaining the consent of the holders of these affected rights. This second contractual stage may be postponed indefinitely or may take place at the time of the private contract. In the latter case, it may be either voluntary or compulsory and total, and, if voluntary, it may also be total or partial. Moreover, jurisdictions also differ in what their registries produce, as they may either simply publicize the deeds evidencing potentially contradictory claims or certify fully purged property rights. Lastly, there is also a logical adaptation of the specific mechanisms needed to produce these outcomes in each environment, the set of rights enforced as property rights, and the adjudication rules in cases of disputed title.

Physically marking the assets is perhaps the simplest way of providing publicity of claims. The symbolic nature of marking makes it especially suitable for abstract rights, such as ownership and security interests. This explains why it has been used extensively for enforcing ownership in the absence of possession, as in valuable movables such as livestock, automobiles, and books. Another simple way of providing publicity is by using conspicuous contractual procedures. For example, ancient Roman law required a formal and public conveyance, either through a collusive proceeding before the court or through a public ceremony known as *mancipatio*. This performed a titling function, as it publicized the conveyance, but it also served to gather the consents of affected right holders and thus purged conflicting claims either at once or after a certain period. Similarly, after 1066, English conveyances followed the continental practice of delivering possession through a ritual known as livery of seisin. The publicity function was even clearer in the practices followed in some European regions, where laws mandated sophisticated procedures of publicity “before the church” and “at the gate of town walls” for rural and urban land, respectively, as well as judicial registration in some cases.

These old practices for reaching consent and purging property rights were effective because transactions mainly took place between neighbors. For neighbors, it is easy to notice announcements and public deals, especially for the kinds of rights common in rural and traditional societies, many of which were linked to family matters. It is revealing that the effect of publicity “before the church” was immediate for right holders who were present but was delayed for one year and one day for those absent. Costlier knowledge was apparently balanced with longer time, suggesting that these systems could hardly support impersonal trade.

The next logical step in the provision of publicity is to lodge private transaction documents (i.e., the title deeds) for filing in a public registry so that this evidence on property claims can then be used by the courts to verify them and allocate property, *in rem*, rights in case of litigation. Moreover, by making this register publicly accessible to potential acquirers, the latter can ascertain the quality of the seller’s title, thus reducing their information asymmetry.

After many failed attempts, such as the Statute of Enrollments issued by Henry VIII in 1535 but never enforced, and the Massachusetts 1640 Recording Act, recordation of deeds eventually started to succeed in the nineteenth century and has been used in most of the United States, part of Canada, France, and some other countries, mostly those with a French legal background. The key for its success was to switch the priority rule, because other incentives had failed to convince people to record. Historically, recordation systems thus became effective only once courts, when deciding on a conflict with third parties, started to determine the priority of claims from the date of recording in the public office and not from the date of the deed. This means that, instead of the conventional “first in time, first in right” rule, courts adjudicate according to the rule “first to record, first in right.” For instance, in terms of a double sale, the judge gives the land not to the first buyer but to the first buyer to record the purchase document.

This change in the priority rule not only protects acquirers but also avoids incomplete

recording, which hampered many of the first recordation systems. The reason is that the switch in the priority rule effectively motivates acquirers to record from fear of losing title through a second double sale or any other granting of rights (e.g., a mortgage) by the former owner to an innocent acquirer (e.g., a lender) who might record first. Consequently, all relevant evidence on property rights is available in the public records. From the point of view of third parties, the record, in principle, is complete. Other claims may not be recorded and may well be binding for the parties who have conveyed them, but these hidden claims have no effect on third parties.

The inclusiveness of the record of deeds makes it possible to assess the quality of title by having experts examine all relevant deeds, that is, only those that have been recorded, and producing “title reports.” If there is sufficient demand, a whole title assurance industry will develop for examining, gathering consents, purging, and assuring title quality. This industry may take different forms. It is composed, for instance, of notaries public in France and of title insurers in many of the United States, while abstractors, attorneys, title insurance agents, and title insurance underwriters perform separate functions in other United States. Despite their different names and differing degrees of vertical integration, the industry performs similar functions in all countries, as it mainly reduces information asymmetry between the conveying parties and encourages them to voluntarily purge the title. In particular, expert search for title defects, which can thus be removed before contracting by obtaining the relevant consent. Alternatively, if not removed, the grantee will not transact or will insist on modifying the content of the private contract, reducing the price or including additional warranties, in compensation for the survival of the defect. To motivate experts’ diligence and technical innovation and to spread remaining risks, a standard close to strict liability is often applied to such examination and assurance activities. Consequently, experts are strongly motivated to find any defects on the title and a substantial part of the remaining title risk is reallocated from acquirers to title experts and their insurers.

Moreover, as under the privacy regime, both contractual and judicial procedures are used to remove title defects. Compared to privacy, deed recordation provides more possibilities for contracting the removal of defects, because defects are better known to buyers and insurers. The identification of right holders also gives greater security to the summary judicial hearings that serve to identify possible adverse claims and publicly reallocate in rem rights. These summary hearings continue to exist today in, for example, the French judicial purge and the US “quiet title” suit. In addition to purging titles directly, the existence of such a court-ordered purging possibility also reduces bargaining costs indirectly by encouraging recalcitrant claimants to reach private agreements.

However, the recording office accepts all deeds respecting certain formal requirements (mainly, the date of the contract and the names of the conveying parties), whatever their legality and their collision with preexisting property rights. In fact, the recording office is often obliged by law to file all documents fulfilling a set of formal requirements, regardless of their legal status. The public record may therefore contain three kinds of deed. First, those resulting from private transactions made without previous examination. Second, those granted after an examination but without having all defects removed. Finally, those that define purged and noncontradictory property rights.

Transactors who record clouded titles therefore produce a negative externality for all future transactors. When examining the title of a parcel, experts do not know a priori which kinds of deed are recorded concerning it. Therefore, for each transaction, they will have to examine all relevant deeds dealing with that parcel, even those which may have been perfectly purged in previous transactions. The cost of this repeated examining of deeds can be reduced with proper organization of the registry. In the short run, the easiest way to organize the information is by relying on indexes of grantors and grantees to locate the chain of transactions for a given parcel. However, this method is subject to errors, such as those caused by identical names and misspellings. This

explains the steps taken, for instance, in 1955 to create the *fichier immobilier* in the French Registry and to forbid recording a deed if the grantor's title is not recorded. Another way of reducing costs when public records are poorly organized is to build privately owned, indexed databases (known in the United States as "title plants"). These plants replicate public records in a more complete, reliable, and accessible manner by transferring and abstracting relevant documents lodged at the public registries and building tract indexes to easily locate the relevant information for each land parcel.

Registration of Rights

Registration of rights (hereafter referred to as "registration," and often confusingly called "title registration") goes one crucial step further than recordation of deeds: instead of providing information about claims, it defines the rights (what, in jurisdictions with Torrens registries, is often referred to as "title by registration"). To do this, it requires a mandatory purge of claims before registering the rights. As in deed recordation, claims stemming from private transactions gain priority when transaction documents are first lodged with the registry. They are then subject, however, to substantive review by the registrar in order to detect any potential conflict that might damage other property rights. New and reallocated rights are registered only when the registrar determines that the intended transaction does not affect any other property right or that the holders of these affected rights have consented. When these conditions are met, the change in rights caused by the transaction is registered, antedating the effects of registration to the lodging date. (In a sense, any registry of rights thus contains a recording of deeds: its "lodgment" or "presentment" book is a temporary record of claims.) Otherwise, when the consent of an affected right holder is lacking, registration is denied, and the conveying parties have to obtain the consents relevant to the originally intended transaction, restructure it to avoid damaging other rights, or desist.

Registration aims to eliminate all uncertainties and information asymmetries, as information in the register is simplified in parallel with the purge of rights. Ideally, rights defined in each new contract are registered together with all surviving rights on the same parcel of land. Extinguished rights are removed or deleted, making it easy to know which are the valid rights. Production of information is a key element. As pointed out by Baird and Jackson, "in a world where information is not perfect, we can protect a later owner's interest fully, or we can protect the earlier owner's interest fully. But we cannot do both" (1984, p. 300). The assertion is accurate but the assumption is crucial: registration intends to produce perfect information and thus protect both the earlier and the later owners. Its goal is to abide by three principles traditionally deemed desirable for a titling system, according to which: (1) the register reflects the reality of property rights, so that potential transactors do not need to look out of the register ("mirror principle"); (2) the register reflects only valid rights, so that transactors do not need to perform a title search in the chain of title ("curtain principle"); and (3) losses caused by a registry's failure are indemnified ("assurance, insurance, or guarantee principle").

To the extent that these three principles are achieved and given that any contradictions are purged before registration, the registry is able to provide "conclusive," "indefeasible" title, meaning that a good faith third party "for value" (i.e., one who pays for the property rather than receiving it as a gift) acquires a property right if the acquisition is based on the information provided by the registry. If the seller's right is later shown to be defective, the buyer keeps the property – that is, in rem – right and the original owner gets contract in personam rights against the seller and the registry. When functioning correctly, the register is thus able to provide potential transactors with a complete and updated account of the in rem rights alive on each parcel of land. Given the enforcement advantage of in rem rights, this accounting amounts to commoditizing the legal attributes of rights on real property, which makes impersonal trade much easier.

Furthermore, registration interferes little with private property, as registry intervention focuses

on the timing and completeness of the reallocation of rights implicit in any purge. Registration is controlled by registrars, but ultimate decisions are made by right holders by giving their consent. Privacy and recordation allow conveying parties more discretion on timing and heavier reliance on privately produced information. They therefore seem to rely more on private decisions, but this perception is deceptive because even recorded titles are in fact mere claims. They retain a higher contractual content, given the survival of conflicting claims in rem. Additional intervention by the court, also subject to the possibility of allocation failure, would be required to transform them into property rights at in rem level equivalent to that provided by registration. In sum, as compared to recordation, it is useful to see registration as a quasi-judicial step, which in other titling systems is also necessary to reach full in rem enforcement. This similar degree of public involvement helps explain why both registration and recordation have taken root in countries with different legal traditions and why there is little correlation between titling systems and legal traditions.

Tort Damages

Louis Visscher
Rotterdam Institute of Law and Economics (RILE), Erasmus School of Law, Erasmus University Rotterdam, Rotterdam, The Netherlands

Definition

The amount of monetary compensation a tortfeasor has to pay to the plaintiff(s) in a tort case when he is found liable.

Introduction

Liability rules in tort law determine when a tortfeasor is liable. The rules of tort damages

determine the amount the liable tortfeasor subsequently has to pay. Together these two bodies of law therefore determine in which situations the tortfeasor has to pay how many damages to the plaintiff(s). Therefore, the behavioral incentives provided by tort law depend on both sets of rules. In this entry, the most important insights from the economic analysis of tort damages are presented. The limited space does not allow a full discussion of all possible complications (see Visscher 2009 for a more complete overview), but where relevant such complications are briefly indicated. It is also not possible to include a full discussion of the liability rules themselves, but in the remainder of this introduction, a very brief account of this topic is provided.

The economic analysis assumes that actors are incentivized to take precautionary measures by the threat of liability (tortfeasors) or the prospect of having to bear one's own losses (victims). Such measures can consist of taking care and/or adapting the activity level. Optimal measures are taken when the marginal costs equal the marginal benefits (see, e.g., Schäfer and Ott 2005; Cooter and Ulen 2012). The social benefits of precautionary measures consist of the reduction in expected accident losses (i.e., the probability of an accident multiplied by the magnitude of the losses if an accident happens). The private benefits of a party consist of the reduction in the losses they themselves have to bear. In order to provide socially desirable incentives, tort damages therefore should equal the social losses, which in principle calls for full compensation (*restitutio in integrum*), and negligence should be defined as taking less than socially optimal care.

An essential difference between strict liability and negligence is that under the first rule the tortfeasor is liable irrespective of his care level and under the latter rule he is only liable if he took less than due care. This implies that whereas under strict liability tort damages indeed should be full, under negligence tort damages can be lower, because they only have to make taking due care (and hence escaping liability) more attractive than taking low care (and hence being liable). However, if a negligent tortfeasor is only held liable for the losses which are caused *by his negligence*, this

difference disappears and also negligence requires full compensation.

In bilateral accident situations, where both the tortfeasor and the victim can influence the accident probability, both parties should receive incentives for optimal precautions. Negligence provides optimal care incentives to both parties (the tortfeasor takes optimal care to avoid liability and the victim to minimize the costs he himself has to bear), but strict liability needs a defense of comparative or contributory negligence to achieve this. No liability rule can give optimal activity incentives to both parties, because only the party who ultimately bears the accident losses will choose the correct activity level.

Pecuniary losses are either monetary losses or losses of replaceable goods, where the replacement costs are a good measure of the losses. Nonpecuniary losses consist of damage to irreplaceable things such as family portraits but also health and emotional well-being (Shavell 2004, p. 242). For pecuniary losses, the concept of full compensation is relevant, because damages can make the victim indifferent between the situation without the tort on the one hand and the situation with the tort and with damages on the other hand (also see section “[What is Full Compensation?](#)”). With nonpecuniary losses, it is problematic that money cannot truly compensate such losses, that they cannot be observed directly, and that there is no market so that one needs to apply indirect methods of assessing them (see section “[Non-pecuniary Losses](#)”). In order to provide the correct incentives to the injurer, tort damages should equal the sum of pecuniary and nonpecuniary losses (Shavell 2004, p. 242).

What is Full Compensation?

In many European countries, the *difference hypothesis* of Mommsen is important in assessing the losses which the liable tortfeasor has to compensate. In this approach, the loss consists of the difference between the wealth as it is at a certain moment and the wealth as it would have been at the relevant moment if the loss causing event would not have happened. In economic terms,

this can be expressed as follows: before the accident, the victim had a certain level of utility. After the accident, he has a lower level of utility, and the difference in both utility levels is his loss. Even though Mommsen defined the loss as a difference between two wealth levels, in many jurisdictions also nonpecuniary losses are compensable. Again in economic terms, the decrease in utility can not only be caused by a reduction in wealth but also by a reduction in other sources of utility, which may have a nonpecuniary nature.

As explained in the Introduction, in order to provide correct incentives, tort damages in principle should fully compensate the victim for his losses (Posner 2003, p. 192; Cooter and Ulen 2012; Shavell 2004, p. 236) and should be based on the social losses. This way, the tortfeasor internalizes the negative externality he has created. By receiving an adequate amount of money, the victim can be brought back to his original utility level, or better, to the utility level he would have reached without the tort. Under negligence, if the tortfeasor would have taken due care, the victim also would run a certain risk of being harmed, so that he should not be brought to a position in which he would run no risk at all. This implies that the victim should not be compensated for losses which also would have happened at due care (Van Wijck and Winters 2001).

Several remarks can be made regarding the principle of full compensation:

- If victims can mitigate their losses by taking measures which cost less than the reduction in accident losses they yield, they should be incentivized to do so. Limiting damages to optimally mitigated losses plus mitigation costs provides the proper incentives (Shavell 2004, p. 248ff).
- If repair is more expensive than replacement, damages should be based on replacement. If repair or replacement is not (completely) possible, monetary damages should be high enough to bring the victim back to his original utility curve.
- Costs which the victim would have incurred anyway should not be compensated (e.g., gasoline costs of a rental car which is needed during repair of the victim's car).
- Damages should take interest, taxes, and inflation into account. For future losses, there is a preference for lump sum rather than periodic contingent payments. A victim who prefers periodic payments can convert the lump-sum payment into periodic payments, lump-sum payment avoids the uncertainties of periodic contingent payment as well as possible moral hazard on the side of the victim, and the victim is not confronted with ongoing monitoring to assess the extent of the losses which would be required under periodic contingent payment (Rea 1981, p. 132).
- The injurer has to compensate the losses of the victim, also if they are higher than normal. Such losses should not be limited on the basis of foreseeability or adequacy but rather the tortfeasor should take the victim as he finds him. After all, limiting damages if they are higher than normal would result, on average, in too few incentives (Shavell 2004, p. 239).
- Judicial moderation and limitation of damages are generally critically assessed by law and economics scholars, because they result in less than full compensation. The often-heard argument of uninsurability of the full losses is not convincing, because it is not primarily the magnitude of losses that results in uninsurability but uncertainty regarding the accident probability. Restricting liability does not solve that issue and might even result in higher losses by diminishing tort law's care incentives (Cooter and Ulen 2012; Shavell 2004, p. 230ff). Restricted liability may induce a potential tortfeasor to engage in a socially desirable activity which he, due to risk aversion, might not engage in otherwise. But it could also induce a potential tortfeasor to engage in an activity which is socially *undesirable* due to the high costs, of which he now only has to bear a fraction.
- One could base damages not on the true losses in individual cases but on the average loss. Such an abstract, objective method of damage assessment instead of a concrete, subjective method can greatly reduce the administrative

costs of tort law. For example, tort damages for a damaged car can be based on the costs of repair by a competent mechanic, even if in the actual case the victim did not have the car repaired or did it himself. The reduction in administrative costs in such often-occurring losses outweighs the possible disadvantage of less fine-tuned deterrence incentives. It is even the question if there is a reduction in deterrent incentives in the first place, because a better damage assessment *ex post* does not result in better incentives if the tortfeasor *ex ante* does not know the exact losses he may cause. As long as the abstract method assesses the average damages correctly, the injurer receives the correct incentives (Kaplow and Shavell 1996). If losses are systematically over (under) estimated, the tortfeasor is generally assumed to choose a too high (low) care level and a too low (high) activity level.

- Harm to the victim generally speaking is a better basis for tort damages than gain to the injurer. In the latter case, if courts would underestimate the gain, the incentives would be inadequate (Polinsky and Shavell 1994, p. 431ff). Furthermore, basing damages on the loss results in internalization of the externality and allows an activity which yields more benefits than costs to be continued. However, if harm to the victim is difficult to assess, e.g., due to its subjective nature, basing damages on the gain may provide better deterrent incentives. Also if one wants to fully deter the behavior, rather than “merely” inducing the tortfeasor to take optimal precautionary measures, basing damages on gain is preferable.
- If litigation costs are taken into account, optimal damages may differ from full compensation of harm (Polinsky and Shavell 2014).

Nonpecuniary Losses

As explained in the Introduction, nonpecuniary losses are difficult to assess because they cannot be observed directly (see e.g. Arlen 2013, p. 439ff). This could induce victims to overstate such losses, and therefore it is sometimes

suggested not to compensate them at all when they are likely to be small. This would greatly reduce administrative costs and only have a limited impact on deterrence. Adams provides a different argument why such losses should not be compensated. Victims who have to bear these losses themselves receive desirable behavioral incentives (Adams 1989, p. 215ff). The problem with this view is, of course, that tortfeasors then receive too few incentives because they only compensate part of the losses. If nonpecuniary losses are too large to ignore, one could use tables or formulas to determine damages, which is a form of an abstract method as discussed in section “[What is Full Compensation?](#)” In order to avoid structural over- or undercompensation, it is important to try to find a method which assesses such losses correctly on average (if at all possible). This idea will be further developed below.

Given that nonpecuniary losses cannot be observed directly, an indirect way to assess them is required. The most well-known indirect method in this respect is provided by the *insurance theory*. This approach argues that a victim should only receive compensation for losses against which he is willing to insure himself. Otherwise, tort law would force coverage upon him which he does not want, but for which he might have to pay via higher prices for goods or services produced by the liable tortfeasor. According to the insurance theory, nonpecuniary losses do not increase marginal utility of wealth, and hence rational victims are not willing to insure against such losses, because the premium would cost more utility than the expected coverage yields (Friedman 2000, p. 95ff; Shavell 2004, p. 270ff). The fact that in practice there is no demand for such insurance is regarded as corroboration of the line of reasoning. The insurance theory therefore claims that victims should not receive compensation for nonpecuniary losses. The injurer, however, should pay for them, so that liability should be decoupled from compensation (Geistfeld 1995, p. 799ff).

Various critiques regarding the insurance theory have been expressed. First, even if marginal utility of wealth would not increase, potential victims might still want to insure against such

losses because the money they would receive after suffering these losses would mitigate the decrease in the *level* of utility, irrespective of the *marginal* utility of wealth at that point. Second, the fact that there is no demand for insurance against nonpecuniary losses may be caused by imperfect information regarding the extent of nonpecuniary losses, the probability of their occurrence, and the compensation required in respect of them or by countervailing social norms in the form of societal hostility to putting a price on pain and sorrow and legal restrictions such as the indemnity principle (Croley and Hanson 1995, p. 1845ff). Third, the argument that nonpecuniary losses do not result in an increased marginal utility of wealth may be flawed to start with. Empirical research which suggests that marginal utility of wealth decreases after suffering nonpecuniary losses is mostly based on personal injury situations where non-disabled people are asked how they think personal injuries would affect them if they would suffer such losses. It is doubtful whether nondisabled people can accurately assess the impact of such injuries on the marginal utility of money, and insights regarding adaptation suggest that this research results in an underestimation of marginal utility which may in fact increase after the nonpecuniary loss is suffered (Pryor 1993, p. 116ff).

But even if marginal utility would not increase, and even if people would not self-insure against nonpecuniary losses, it is questionable whether this should lead to the conclusion that victims should not receive compensation for such losses. Insurance decisions provide information on the degree of risk aversion of the actor involved but not on his willingness to pay to avoid the loss. If the victim would be willing to forego resources ex ante in order to avoid the nonpecuniary loss or at least to lower the chances of suffering them, this would imply that he does regard these losses as undesirable and that they do lower his utility level. The resources the victim himself is willing to spend on accident avoidance therefore provide information of how the victim himself assesses the nonpecuniary loss. This is a better indirect way of assessing damages for nonpecuniary losses than the insurance decision, which – again – regards risk aversion rather than

loss assessment. By basing damages on the resources victims themselves would have been willing to spend on accident avoidance, the victims are not overcompensated against their will, nor are potential injurers overdeterred because, in essence, they bear the costs of avoidance measures which were worthwhile ex ante.

For fatal accidents, the so-called *Value of a Statistical Life* (VSL) provides information on the willingness to pay to lower the chance of fatal accidents. The VSL is derived from all kinds of decisions people take which affect health and safety, such as wearing a helmet when riding a (motor)bike, installing a smoke detector at home, asking a premium for dangerous work conditions, etc. Such decisions contain an implicit trade-off between money and risks. If, for example, 1,000 people are each willing to spend € 1,000 on a measure which reduces the probability of a fatal accident by one pro mille, one statistical life is saved by spending € 1,000,000. The VSL in this example then is at least € 1,000,000 because this population was willing to spend at least that amount. In 2004, Sunstein assessed the VSL at about \$6.1 million (Sunstein 2004, p. 205; Posner and Sunstein 2005, p. 563). Expressed in 2014 euros this would amount to about €6.4 million. This American VSL is comparable to that in other developed countries (Viscusi and Aldy 2003, pp. 24, 35, and 63). If one wants to distinguish between victims on the basis of their age, one should use the *Value of a Statistical Life-Year* (VSLY) instead. Posner and Sunstein argue that damages for fatal accident which are based on the VSLY should be around \$6 million or higher and including the emotional loss of surviving relatives could result in an increase of several millions of dollars as well (Posner and Sunstein 2005, p. 586ff). These amounts are much higher than currently awarded in European countries, where damages are often limited to funeral costs and loss of maintenance. This implies that from an economic point of view, damages for fatal accidents are structurally undercompensated.

Schäfer and Ott argue that for nonfatal injuries, damages should be “some fraction” of the value attached to the willingness to pay to prevent death (Schäfer and Ott 2005, p. 373), but they do not

suggest how the appropriate fractions could be determined. The concept of the *Quality-Adjusted Life-Year* (QALY) could play a good role here (Miller 2000; Karapanou and Visscher 2010). QALYs express the value of living 1 year in a certain health condition, which is a proxy of the quality of life during that period. By combining information regarding the QALY value of that health condition and the duration thereof on the one hand and a monetary value of a QALY on the other hand, it is possible to express in monetary terms the loss of utility due to suffering personal injuries. QALYs are used to evaluate health programs and medical treatments and techniques and hence express how much society is willing to prevent or cure the health conditions under consideration. They therefore can provide information on the societal willingness to pay to avoid or cure such losses and are therefore suitable as a basis for the assessment of pain and suffering damages for personal injuries. It turns out that applying this method, even with conservative monetary values, results in higher pain and suffering damages than currently awarded in most European countries, so that here as well, currently these losses are structurally undercompensated.

Pure Economic Loss

In the Introduction, it became clear that tort damages should in principle be based on the social loss the tortfeasor has caused. In cases of pure economic loss, the private losses of the victim often do not coincide with the social loss. The private losses might be offset by private gains elsewhere, so that the tort resulted in a redistribution of social welfare rather than in a reduction thereof. If firm A cannot produce due to a power supply interruption caused by a tort, but firm B now produces and sells more, there might not be a social loss at all, and tort liability then makes no economic sense. This redistribution argument is regarded as a reason not to include pure economic loss in tort damages (Bishop 1982; Gómez and Ruiz 2004; Dari-Mattiacci and Schäfer 2007, p. 10). However,

several reasons exist why there might be a social loss after all.

First, the products of firm B might not be a perfect substitute so that there is a loss of consumer surplus.

Second, firm B had to have overcapacity in order to meet the additional demand, and overcapacity in itself can be regarded as inefficient. Compensating pure economic loss provides better behavioral incentives to potential tortfeasors, resulting in fewer accidents and hence a reduced need for overcapacity (Rizzo 1982, p. 202).

Third, there will be many cases of pure economic loss where there is not only a redistribution of wealth but also a decrease in social welfare. For example, if an accountant negligently approves the balance sheet of a firm, besides the redistribution of welfare between buyers and sellers of overpriced stock, such faults may decrease trust in information provided by accountants and induce parties to do additional research and result in suboptimal investment decisions. These are all examples of social losses.

Gómez and Ruiz present two other reasons why pure economic loss should sometimes be included in tort damages. In situations where the victim in essence “insured” someone else against losses by covering them, it is desirable that he can recover his pure economic loss from the tortfeasor due to the same reasons why subrogation in real insurance contracts is desirable. An example of this is an employer who pays wages to his employee also during the period where the latter cannot work because he is injured in a tort. It is also possible that a third party suffers pure economic loss due to breach of contract. The third party might not be able to recover these losses under contract law because he is no party to the contract. Tort law could then serve as a surrogate for contractual liability (Gómez and Ruiz 2004).

Punitive Damages

Punitive damages are damages which exceed compensatory damages and are used to punish wrongdoers in cases of, e.g., malice, gross

negligence, or intent. Continental European jurisdictions generally do not award punitive damages. In debates regarding punitive damages, a fear for “American situations” in which enormous amounts of damages are awarded is often expressed. However, such large amounts are often reduced by courts, and empirical research shows that punitive damages are not often awarded and generally speaking are not very high, and they are correlated with compensatory damages (Cohen and Harbacek 2011; Vidmar and Wolfe 2009, p. 189, However, also see Polinsky 1997). The “American situations” are therefore more myth than reality, and fear for them should not frustrate the debate on introducing punitive damages in continental Europe. This holds even stronger now there are good economic arguments in favor of punitive damages (also see Arlen 2013, p. 488ff).

First, punitive damages can ameliorate the problem that the probability that a tortfeasor will actually be held liable is below 100%. By increasing damages, the *expected* damages can again equal social harm. For example, if the probability of being held liable for causing a loss of 100 is 25%, but total damages (consisting of compensatory and punitive damages) are 400, the expected liability is again 100 ($25\% \cdot 400$) (Cooter 1989; Polinsky and Shavell 1998). This idea is consistent with the fact that punitive damages are often awarded in cases of intentional torts, because there the injurer might try to avoid being caught.

Second, if compensatory damages do not cover all (types of) losses of the victim, damages are too low from an economic viewpoint because they do not cover the full externality. Such undercompensatory damages can result from losses which are difficult to assess, e.g., because they are nonpecuniary or subjective. In principle, punitive damages could tackle this problem. The fact that in cases of defamation (with indeed subjective and nonpecuniary losses) punitive damages are often possible fits this idea. However, in order to assess the correct magnitude of punitive damages, one has to assess the extent of undercompensation of normal damages, and if one would be able to assess that, one could better

increase compensatory damages by this amount (Polinsky and Shavell 1998, p. 940).

Third, if the utility a tortfeasor yields from his activity is regarded as socially illicit so that we do not want to include it into the social weighing of costs and benefits, compensatory damages may not adequately deter the undesirable behavior because the tortfeasor still yields his utility. Punitive damages could result in more deterrent incentives (Cooter 1989, p. 79ff; Shavell 2004, p. 245). The value of this third rationale is limited, because (1) many of the acts which yield socially illicit utility will be subject to criminal liability and (2) labeling certain benefits as socially illicit *assumes* the conclusion that these acts are socially undesirable rather than that this is *proven* on the basis of a weighing of costs and benefits (Friedman 2000, p. 229ff).

Fourth, the threat of punitive damages could induce a potential tortfeasor to seek a voluntary transaction with the potential victim, rather than to commit the tort. Law and economics scholars generally prefer such voluntary transactions because then also subjective elements in the valuation are included in the decision whether or not to transfer an entitlement, whereas tort damages do not include these elements, so that they might not fully compensate the victim. In cases where a voluntary transaction was possible, the potential tortfeasor should be incentivized not to take away the entitlement without consent and to pay the objective damages afterward, exactly because of the possible subjective elements. Punitive damages can help by making the involuntary transfer more expensive (Shavell 2004, p. 245ff).

Fifth, victims who start a tort claim in essence serve the social goal of deterrence, yet they bear all the costs. If the costs outweigh the expected private benefits, they may stay rationally apathetic. Punitive damages, such as treble damages in antitrust cases, may ameliorate this situation.

Sixth and final, in as far as independent value is attached to the punishment goal (the desire of individuals to see blameworthy parties appropriately punished), punitive damages can ensure that more reprehensible behavior results in a more severe sanction (Polinsky and Shavell 1998,

p. 948ff). This is consistent with the fact that punitive damages are often connected to malice, gross negligence, or intent.

Conclusion

As a starting point, tort damages should fully encompass the externality caused by the tortfeasor. Under negligence, lower damages are possible as long as they make taking optimal care more attractive than being negligent. Victims should receive incentives to take optimal precautionary and mitigation measures. Tort damages should encompass both pecuniary and nonpecuniary losses, unless the administrative costs of assessing the latter outweigh the behavioral benefits of including them. In principle, especially for difficult classes of losses, an objective abstract assessment of damages suffices, as long as systematic over- or undercompensation is avoided. It seems that actual nonpecuniary damages for fatal accidents and personal injuries are (much) lower than economically desirable. Pure economic loss should only be compensated if it also entails a social loss. Punitive damages serve several economic goals, and the European debate should not be shut down by a simple reference to “American situations,” which are more myth than reality.

Tourism

Marianna Succurro

Department of Economics, Statistics and Finance,
University of Calabria, Rende (CS), Italy

Abstract

The term tourism indicates all the heterogeneous activities and services referring to the temporary transfer of people from the habitual residence to other destinations for diverse reasons. It is a social, cultural, and economic phenomenon which is very important, and, in some cases vital, for many countries. Over the past decades, tourism has experienced continued expansion and diversification, becoming one of the largest and fastest-growing economic sectors in the world. It generates also direct effects on the social, cultural and educational sectors of national societies and on their international relations. Due to these multiple impacts, there is a need for a holistic approach to tourism analysis, development, management and monitoring in order to formulate and implement national and local tourism policies and international agreements.

Definition

The term tourism indicates all the heterogeneous activities and services referring to the temporary transfer of people from the habitual residence to other destinations for leisure, amusement, entertainment, culture, medical treatment, business, sport, and other purposes.

These people are called visitors (which may be either tourists or excursionists, residents or nonresidents), and tourism has to do with their activities, some of which imply tourism expenditure.

In 1936, the League of Nations defined a foreign tourist as “someone traveling abroad for at least 24 h.” Its successor the United Nations amended this definition in 1945, by including a maximum stay of 6 months.

Tourism and its Multiple Impacts

Tourism is a social, cultural, and economic phenomenon which is very important, and, in some cases vital, for many countries.

Many researchers reckon it is a key driver of socioeconomic progress through export revenues, the creation of jobs and enterprises, and infrastructure development. As such, tourism has implications on the economy, on the natural and built environment, on the local population at the destination, and on the tourists themselves.

In the *Manila Declaration on World Tourism of 1980*, tourism is recognized as “an activity essential to the life of nations because of its direct effects on the social, cultural, educational, and economic sectors of national societies and on their international relations.” Due to these multiple impacts, there is a need for a holistic approach to tourism analysis, development, management, and monitoring in order to formulate and implement national and local tourism policies and international agreements.

The Increasing Importance of Tourism in the World as Consumer Good

The origins of modern tourism can be traced back to the traditional trip of Europe undertaken by mainly upper-class European young men. The custom flourishes from about 1660 until the advent of large-scale rail transit in the 1840s, usually associated with a standard itinerary.

Mass tourism develops with the improvements in infrastructures and technology, allowing the transport of large numbers of people in a short space of time to places of leisure interest, so that greater numbers of people can begin to enjoy the benefits of leisure time.

Over the past six decades, indeed, tourism has experienced continued expansion and diversification, becoming one of the largest and fastest-growing economic sectors in the world. Many new destinations have emerged in addition to the traditional favorites of Europe and North America.

Despite occasional shocks, international tourist arrivals have shown virtually uninterrupted

Tourism, Fig. 1 Inbound tourism by purpose of visit, 2013 (share) (Source: World Tourism Organization)

growth from 25 million in 1950 to 278 million in 1980, 528 million in 1995, and a record of 1087 million arrivals in 2013 (UNWTO 2015).

Nowadays, tourism is considered a popular global leisure activity.

Most travel is for leisure purposes (52%), followed by health and religion purposes (27%), business (14%), and others (Fig. 1).

According to the UNWTO's long-term forecast *Tourism Towards 2030*, international tourist arrivals worldwide are expected to increase by 3.3% a year from 2014 to 2030 to reach 1.8 billion by 2030.

The developments in technology and in transport infrastructure, such as low-cost airlines and more accessible airports, have also made many types of tourism more affordable. Internet sales of tourist services have facilitated changes in lifestyle. Some sites have started to offer dynamic packaging, in which an inclusive price is offered for an appropriate package requested by the customer (see paragraph 4.1 on ICT and tourism distribution).

Tourism Data and Statistics

Secondary Data and Statistics

Worldwide Tourism Statistics

The United Nations World Tourism Organization (UNWTO) *Tourism Highlights* is a very useful source for a long-term outlook on tourism. The

UNWTO is the United Nations' agency responsible for the promotion of responsible, sustainable, and universally accessible tourism. As the leading international organization in the field of tourism, UNWTO promotes tourism as a driver of economic growth, inclusive development, and environmental sustainability and offers leadership and support to the sector in advancing knowledge and tourism policies worldwide. It is the leading organization collecting and disseminating the most up-to-date and comprehensive tourism data, short- and long-term forecasts, and knowledge on specific and source markets; thus it serves as a global forum for tourism policy and a source of tourism know-how.

The *UNWTO Tourism Towards 2030* is UNWTO's long-term outlook and assessment of the development of tourism for the two decades from 2010 to 2030, and it has become a worldwide reference for international tourism forecasts.

Understanding, for each country, where its inbound tourism is generated is essential for analyzing international tourism flows and devising marketing strategies, such as those related to the positioning of national markets abroad.

UNWTO's main dataset and publication on annual tourism statistics include:

- *Yearbook of Tourism Statistics*, which, deriving from the most comprehensive statistical database available on the tourism sector, focuses on data related to inbound tourism

(total arrivals and overnight stays), broken down by the country of origin

– *Compendium of Tourism Statistics*

Complete data and statistics for European countries are also available from the Eurostat database.

National Institutes of Statistics

Additional statistics can be found in publications on tourism made available by the National Institute of Statistics in each country.

The United Nations General Assembly has endorsed the *Fundamental Principles of Official Statistics* (last 29 January 2014). These principles are considered a basic framework which all statistical activities developed by national and international organizations must follow in recognizing official statistics as a public good.

Tourism Satellite Account (TSA)

The *Tourism Satellite Account* (described in the *Tourism Satellite Account: Recommended Methodological Framework 2008*) is, besides the *International Recommendations for Tourism Statistics 2008*, the second international recommendation on tourism statistics that has been developed in a framework of consistency with the System of National Accounts. Both recommendations are mutually consistent and provide the conceptual framework for measuring and analyzing tourism as an economic activity in each country.

As a statistical tool for the economic accounting of tourism, the TSA can be seen as a set of ten summary tables, each with their underlying data and representing a different aspect of the economic data relative to tourism: inbound domestic tourism and outbound tourism expenditure, internal tourism expenditure, production accounts of tourism industries, and the gross value added (GVA) and gross domestic product (GDP) attributable to tourism demand, employment, investment, government consumption, and non-monetary indicators.

The purpose of a Tourism Satellite Account is to analyze in detail all the aspects of demand for goods and services associated with the activity of visitors, to observe the operational interface with

the supply of such goods and services within the economy, and to describe how the supply interacts with other economic activities. It should permit greater internal consistency of tourism statistics with the rest of the statistical system of a country as well as increased international comparability of these data. TSA is highly recommended to evaluate the role that tourism sector performs in the entire economy as well as to allow processing and comparison at an international level.

Primary Data: Surveys

Where the required secondary data support is unavailable for an economic impact analysis, primary data collection from survey sampling is probably the only way forward. This approach can provide useful information where more sophisticated methods are not applicable, but the results should be used with caution due to sampling biases. Careful statistical treatments with the raw data are also needed.

International Tourism: An Overview

In 1994, the United Nations classified three forms of tourism in its *Recommendations on Tourism Statistics*:

- Domestic tourism, involving residents of the given country traveling only within this country
- Inbound tourism, involving nonresidents traveling in the given country
- Outbound tourism, involving residents traveling in another country

International tourist arrivals (overnight visitors) grew by 5% in 2013, reaching a record 1087 million arrivals worldwide, up from 1035 million in 2012.

International tourism receipts are the earnings generated in destination countries from expenditure on accommodation, food and drink, local transport, entertainment, shopping, and other services and goods. In macroeconomic terms, expenditure by international visitors counts as exports for the destination country and as imports for the

country of residency of the visitor. In 2013, international tourism receipts in destinations around the world grew 5% in real terms (taking into account exchange rate fluctuations and inflation) to reach US\$ 1159 billion (euro 873 bn). The growth in receipts mirrored the growth in international arrivals (also +5%), confirming the strong correlation between these two key indicators of international tourism.

Table 1 reports the most visited countries in 2013 in terms of the number of international tourist arrivals. Table 2 reports the top ten tourism earner countries for the year 2013.

Source: UNWTO (2014) Tourism highlights

In the ranking by arrivals, Europe leads the growth in absolute terms, while Asia and the Pacific record the fastest relative growth across all the regions. France continues to top the ranking of international tourist arrivals and is third in international tourism receipts. The United States ranks first in receipts and second in arrivals. Spain is still the second largest earner worldwide and the first in Europe and ranks third in arrivals. China moves to fourth in arrivals and remains fourth in receipts. Italy consolidates its fifth place in arrivals and sixth in receipts. Turkey remains sixth in arrivals and 12th in receipts. Thailand enters the top ten arrivals ranking at number ten, climbing amazing five positions, while it moves up two places to seventh in the ranking by tourism receipts. Germany and the United Kingdom remain, respectively, seventh and eighth in arrivals, but move down one place each in terms of earnings to eighth and ninth places, respectively. The Russian Federation completes the top ten ranking by arrivals in ninth place, while the two Chinese Special Administrative Regions Macao and Hong Kong rank, respectively, fifth and tenth in receipts (UNWTO *Tourism Highlights* 2014).

World's Top Tourism Destinations

When ranking the world's top international tourism destinations, it is preferable to take more than a single indicator into account. Ranked according to the two key tourism indicators – international tourist arrivals (Table 1) and international tourism

Tourism, Table 2 International tourist receipts

Rank	US\$				Local currencies	
	Billion		Change (%)		Change (%)	
	2012	2013*	12/11	13*/12	12/11	13*/12

10 Hong Kong (China)	33.1	38.9	16.2	17.7	15.8	17.7

Source: UNWTO (2014) Tourism highlights

receipts (Table 2) – it is interesting to note that eight of the top ten destinations appear on both lists, despite showing marked differences in terms of the type of tourists they attract and in average length of stay and spending per trip and per night. In the case of international tourism receipts, changes not only reflect relative performance but also (to a considerable extent) exchange rate fluctuations between national currencies and the US dollar.

The World Tourism Organization also ranks countries on the base of their total expenditure on international tourism for the year 2013. Table 3 reports the top ten countries.

Tourism Distribution Channels

Two of the most important factors influencing the competitiveness and success of a tourist destination are the efficiency and effectiveness of distribution channels (Buhalis and Laws 2001).

Tour operators play a significant role in the promotion and marketing of tourist products. This is particularly true for small and medium accommodation structures and emerging regions which do not have sufficient expertise and financial resources to invest in advertising and in the widespread distribution of their products (Buhalis 2000; Succurro 2008).

The negotiation between tourist firms and intermediaries, primarily aimed at increasing

visibility and competitiveness of services supplied, is relevant to the success of both the tourist firms and the tourist destinations as a whole. Moreover, an appropriate promotion and distribution of products have direct consequences on a balanced use of accommodation establishments. High seasonality, indeed, is one of the most problematic aspects in the tourist sector; many destinations suffer from this phenomenon every year.

Both the seasonality problem and the relative importance of traditional tour operators have been strongly affected by the new technologies. Reduced search costs and direct online organization of the trip are two prominent aspects of the tourism industry that have been deeply affected by recent technological advances. Tourism providers, indeed, can now sell their services directly through the web by avoiding intermediaries. Recent studies explore the capacity management issue under time-varying demand (i.e., the seasonality issue), the tourist information acquisition process, and, finally, the impact of online booking on tourism flows and seasonality (Jang 2004; Boffa and Succurro 2012).

ICT and Tourism Distribution

Over the last 20 years, the Internet has changed various facets of social life, creating many social

Tourism, Table 3 Top ten biggest spenders, 2013

Rank	International tourism expenditure (US\$ billion)		Local currencies change (%)		Market share (%)	Population (million)	Expenditure per capita (US\$)

concerns (Kim 2010). A large diffusion of the ICT in the tourism sector has improved its social and economic impacts, from which many consumers and organizations can benefit (Minghetti and Buhalis 2010). Indeed, the Internet has grown to be one of the most effective means for tourists to seek information and purchase tourism-related products (Pan and Fesenmaier 2006).

The Internet plays a key role in the development of the tourism industry since it encourages people to travel both by improving access to the destinations and by reducing search costs (Boffa and Succurro 2012). With the advent of e-commerce, indeed, tourism products have become one of the most traded online items.

Technological progress, coupled with regulatory changes, has modified the nature of tourists' search process in at least two directions. First, it has expanded consumption opportunities (e.g., by decreasing the cost of reaching relatively far destination) and, as a result, the expected benefit of searching for a tourist destination. Second, it has decreased the costs of direct search, for example, through the release of faster and more reliable search tools, thanks to the Internet. The two effects contribute to making the direct online search process less time-consuming and more valuable, hence more productive.

Tourism Research

Despite the debate about its definition over the past decades, tourism is commonly recognized as a human activity which can be analyzed from different perspectives. As a field of study, tourism is gradually evolving from a multidisciplinary endeavor into an interdisciplinary stage of research (Tribe and Xiao 2011). Thus, in order to advance the understanding of tourism, it is necessary to integrate economics with other social sciences including law, psychology, sociology, and political science and to seek new holistic approaches and tools.

Numerous disciplinary contributions in diverse areas of research have supported the emergence of tourism as a field of academic study or an autonomous discipline. The epistemology of tourism

research, however, is still the subject of ongoing discussion and debate (Benckendorff and Zehrer 2013).

Economic Analysis

In the wider context of tourism knowledge creation, economics has played a significant role.

Tourism generates directly and indirectly an increase in economic activity in the destinations visited, mainly due to demand for goods and services that need to be produced and provided.

In the economic analysis of tourism, one may distinguish between tourism's economic *contribution* which refers to the direct effect of tourism and is measurable through the Tourism Satellite Account (TSA) and tourism's economic *impact* which is a much broader concept encapsulating the direct, indirect, and induced effects of tourism which must be estimated by applying models to provide the simulations (Dwyer et al. 2007; Song et al. 2012). Thus, economic impact studies aim to quantify economic benefits, that is, the net increase in the wealth of residents resulting from tourism, measured in monetary terms, over and above the levels that would prevail in its absence.

Because of the evolution of tourism as an economic activity over the past 50 years, there has been a significant growth of publications in specialized journals (*Annals of Tourism Research*, *Tourism Economics*, *Tourism Management*, *Journal of Travel Research*, to cite some of them) and several key texts on tourism economics (more recently, Dwyer et al. 2010; Stabler et al. 2010; Tribe 2011). Several scientific articles have also attempted to provide an overview of the developments in tourism economics (see, as relatively more recent works, Eadington and Redman 1991; Sinclair 1998; Tremblay 1998; Sinclair et al. 2003; Dwyer et al. 2011).

Macroeconomic Analysis

From a macroeconomic perspective, tourism contributes to both destination competitiveness – defined in different ways and measured by different methodologies – and local, national, and international economic development. Over the last few decades, indeed, a popular topic in tourism research has been the evaluation of the

economic, social, and environmental impact of tourism and its policy implications.

With reference to the economic impact, proponents of the tourism-led growth hypothesis focus on the relationship between tourism and economic growth and emphasize the role of tourism in spurring local investments, exploiting economies of scale, increasing employment, and diffusing technical knowledge (Schubert et al. 2011). The employment effect of tourism, the quality and structure of employment, and the gender wage gap are other well-established and interdisciplinary research areas which also draw on insights from sociology and political science.

With reference to the tourism-led theory, many studies confirm a unidirectional causality from international tourism to real GDP in specific countries or regions, while other studies find evidence of bidirectional relationships. The main criticism faced by the tourism-led growth studies relates to their reliance on the use of a methodology – the Granger causality test – which does not necessarily suggest the real cause-effect relationship (Song et al. 2012).

Note that recent research stresses that tourism does not always increase economic welfare. In fact, a tourism boom may lead to “deindustrialization” in other sectors due to a phenomenon known as the “Dutch Disease effect.”

Moreover, as a significant form of international trade flows, tourism also lies within the scope of international economics studies. A number of studies find supportive evidence of the bidirectional causality between international tourism and international trade. Also these studies usually rely on the Granger causality test with the subsequent aforementioned criticism.

With reference to the environmental issues, tourism production and consumption generate environmental consequences, and at the same time, tourism activities are strongly affected by the quality of the environmental resources. In the tourism industry, and differently from the manufacturing industries, the environment is not only an input factor but also a key component of its output (Razumova et al. 2009). For this reason, an increasing attention has been paid to sustainable tourism and climate change topics – both at

the micro- and macrolevel of analysis – and to discussions about the appropriate instruments for environmental governance. Several price-based instruments, semi-price instruments such as quotas, and non-price instruments, such as government regulations and industry voluntary management, have been proposed and discussed theoretically in the tourism literature.

Microeconomic Analysis

From a microeconomic perspective, economic studies are complex and cover several topics. In the recent tourism economic literature, departing from the old debate about whether tourism is an industry or a market, it has been commonly recognized that tourism cannot be defined as either an industry or a market. Clarification of this confusion has important implications for economic analysis in this field (Wilson 1998). More specifically, “. . . tourism is a composite product that involves a combination of a variety of goods and services provided by different sectors, such as transport, accommodation, tour operators, travel agencies, visitor attractions, and retailing. Moreover, tourism products are serviced and transacted in different markets” (Song et al. 2012). For this reason, diverse topics have been developed from both the demand and supply perspectives.

Demand Analysis The dominant position of demand analysis and its determinants is still observable in the latest developments in both theoretical and empirical tourism economic studies. Tourism demand is predominantly measured by the number of arrivals, by the level of tourist expenditure (receipts), and, more recently, by the number of tourist nights (length of stay). The key research tasks in tourism demand studies include the selection of the best specified models for modeling and forecasting tourism demand, the identification of the key economic determinants of tourism demand, and the computation of demand elasticities and, associated with globalization, market interdependence.

Supply Analysis The tourism supply analysis usually follows that of industrial economics. The well-known structure-conduct-performance (SCP)

paradigm has provided a useful framework for studying tourism supply from a market perspective. The SCP paradigm suggests that the type of the market structure within which a firm operates (e.g., monopoly, monopolistic competition, oligopoly) determines a firm's conduct (e.g., pricing strategies, marketing investment, innovation) which ultimately affects its overall performance (mainly productivity, efficiency, and long-term growth). A number of empirical studies have tested the SCP paradigm in tourism, but the findings are inconclusive due largely to the different empirical settings and methods used. Newer approaches take into account the dynamic nature of the market – on the base of game theory approach – and its institutional arrangements.

In addition to the above topics, industry agglomeration and clustering, with the economic importance of geographic location, have become an emerging topic in recent tourism supply studies. The new geographical economics, indeed, provides useful perspective for interfirm relationships.

Adjectival Tourism

Many niche or specialty travel forms of tourism have come into a common use by the tourism industry and academics. Among the various forms of tourism: individual tourism, collective tourism, organized tourism, educational tourism, young tourism, third-age tourism, business tourism, sustainable tourism, and ecotourism.

Other forms of “adjectival tourism” include agritourism, birth tourism, culinary tourism, cultural tourism, extreme tourism, geotourism, heritage tourism, medical tourism, nautical tourism, religious tourism, sex tourism, and wildlife tourism.

Sustainable Tourism

Tourism's rapid growth calls for a greater commitment to the principles of sustainability to amplify tourism's benefits and mitigate its possibly negative impacts on the environment and on societies.

The key issues in sustainable tourism, indeed, are defined by the fundamentals of sustainability, external to the literature of tourism research, and linked to science, environment, resource management, global change, human health, economics, and development policy (Buckley 2012).

From a more general perspective, indeed, and as reported by the World Commission on Environment and Development (officially dissolved in December 1987), sustainable development implies “meeting the needs of the present without compromising the ability of future generations to meet their own needs.” Thus, sustainable development would at least maintain ecological integrity and diversity to meet human needs.

Tourism researchers turned their attention to social and environmental issues almost four decades ago. Research using the specific term *sustainable tourism* started around two decades ago.

Specifically, “sustainable tourism is envisaged as leading to management of all resources in such a way that economic, social and aesthetic needs can be fulfilled while maintaining cultural integrity, essential ecological processes, biological diversity and life support systems”.

Sustainable tourism can be seen as having regard to ecological and sociocultural carrying capacities and includes involving the community of the destination in tourism development planning. It also involves integrating tourism to match current economic and growth policies so as to mitigate some of the negative economic and social impacts of mass tourism.

There is a myriad of definitions for sustainable tourism, including ecotourism, green travel, environmentally and culturally responsible tourism, fair trade, and ethical travel.

Ecotourism

Ecotourism, also known as ecological tourism, is responsible travel to fragile and usually protected areas that strives to be low impact and (often) small scale. It helps educate the traveler, provides funds for conservation, directly benefits the economic development and political empowerment of local communities, and fosters respect for different cultures and for human rights.

Summary/Conclusion/Future Directions

Economics has played a significant role in studying tourism, considered as a key driver of socio-economic progress. In the wider context of tourism knowledge creation, however, there is a need for a holistic approach to tourism analysis. Thus, it would be desirable to integrate economics with other social science disciplines.

Tournament Theory

Martin Schneider

Faculty for Economics and Business
Administration, University of Paderborn,
Paderborn, Germany

Abstract

In tournament theory the effects of competitions in which the best performers are awarded a fixed prize are studied. The tournament idea has been used to explain career patterns in large US law firms and in European judicial hierarchies. It has also been suggested in a prescriptive way as a method to select judges for the US Supreme Court. Tournaments theory helps to understand under which conditions lawyers and judges engage in a rate race to achieve promotion. But important assumptions of the formal tournament models are not met in practice, so real tournaments are unlikely occur in practice. The theory should therefore not be interpreted as an exact descriptive or prescriptive model of behavior but rather as a useful metaphor to help understand empirical patterns.

Synonyms

Contest theory

Fundamentals

Tournament theory utilizes the metaphor of a sport tournament to analyze certain types of competition between players more generally. In a tournament, the prize of a competition is awarded to a fraction of all competitors with the best performance. Hence, a tournament is distinct from other types of competition by two characteristics. First, the winner prize and the fraction of winners are specified in advance of the competition. Second, the prize is awarded not on the basis of some absolute performance standard but on the basis of relative performance (rank-order tournament).

The idea of a tournament has been suggested for the first time within labor economics and human resource management to describe competition among employees for promotion in an organizational hierarchy (Lazear and Rosen 1981; Rosenbaum 1979, 1984). Since then the tournament idea has been most widely applied to explain the pay structure within companies. It has also been adopted in a range of disciplines including law (more on this below), ecology, finance, and psychology (Connelly et al. 2014).

The basic formal model (Lazear and Rosen 1981) is a game with two identical risk-neutral agents and one principal. The principal seeks to elicit effort from the two agents by setting a tournament prize for the winner, i.e., for the agent with the highest output (output can be measured, effort cannot). Each agent maximizes utility by selecting the level of effort, given the impact of effort on the probability of winning, the prize, and the disutility from effort. At the utility-maximizing level of effort, the marginal disutility from effort is equal to the marginal increase in the probability of winning times the prize. Since agents are identical and the probability of winning depends on the other agent's effort, the tournament incites a rat race among the agents. None of the agents has an incentive to reduce effort because effort reduction implies that the other agent will win. The principal

can implement the optimal amount of effort by manipulating the prize, i.e., the difference between the winning and the losing pay level.

In terms of incentives effects, this basic model has two main testable hypotheses (Connelly et al. 2014). First, agents' effort increases with the prize, i.e., with the difference between the winning and losing pay level. Second, it is only this prize not the absolute winning pay level that matters for agents' effort.

The basic formal model has been extended in various directions (Connelly et al. 2014). There may be a succession of tournaments at different levels of an organization rather than a single competition. More than two players may compete. Agents may be heterogeneous. They may be able to influence each other's output (e.g., through sabotage). And output may be influenced by luck to varying degrees.

While the basic formal model focuses on deriving a prize that provides an optimal level of incentives, tournaments may also be implemented for other reasons, namely, to select certain players and to commit the principal to a certain policy (pay, promotion) in advance.

Tournaments of Lawyers and Judges

From a law-and-economics perspective, applications of the tournament idea on judiciaries and law firms are particularly interesting. It has been suggested that certain ("elite") law firms in the USA have implemented more or less rigid tournament models in the early twentieth century (Galanter 1994; Galanter and Palay 1990). In essence, these firms have committed to promoting a certain percentage of associates to partners each year, thus incentivizing younger associates and building up pressure in the firm as a whole to maintain revenues. This tournament, it has been argued, can explain the growth of these law firms in the twentieth century. In the big law firms, competition for partnerships is now restricted to the higher ranks ("elastic tournaments") (Galanter and Henderson 2008). Tournament theory and the idea of up-or-out competition have become the main theoretical perspective to

explain the labor market for lawyers in the large law firms in the USA and elsewhere (Wilkins and Gulati 1998).

Tournament theory has also been used to examine competition among judges for assignment or promotion. Judiciaries in civil law countries such as Germany resemble internal labor markets. Judges enter at the bottom of the hierarchy, they are tenured, and they may be promoted to higher judicial positions (Schneider 2004, 2005). The way judges are selected, the fact that pay is attached to judicial positions and observed data on promotions are in line with the idea that a succession of rank-order tournaments takes place between judges. While the tournament model was used here in a descriptive and explanatory way, another application is prescriptive. In order to avoid politicized nomination, it has been suggested that a tournament might be an appropriate method to select judges for the US Supreme Court (Choi and Gulati 2004a). As a possible criterion for promotion, a rank order of judges has been compiled based on various output measures (Choi and Gulati 2004b).

Why Tournaments?

Tournaments may be considered an efficient incentive mechanism. In contrast to an obvious alternative, namely, paying workers directly according to productivity, the measurement of output is easier. This is because, to determine the winner in a tournament, output needs not be measured continuously; an ordinal measure – a rank order – is sufficient. For both lawyers in law firms and for judges, the provision of incentives has been suggested a reason for the practice of tournament-like promotions (Schneider 2005; Choi and Gulati 2004a; Galanter and Palay 1990).

In addition, tournaments may exert favorable selection effects. If productivity in the current job predicts productivity in a job higher up in the hierarchy, then tournaments may help to identify the best lawyers and judges for more important positions in the law firm and the judiciary. This

selection effect of a tournament was considered particularly attractive for judicial positions. Here, a tournament promises to be transparent and objective, while alternative mechanisms are plagued with political bickering and tend to bring to office judges based on their political leanings (Choi and Gulati 2004a).

Tournaments, finally, are also a commitment device. Because prize, the rate of winners, and the output measure need to be specified in advance and are observed easily, workers may trust that effort will be rewarded and the employer will not renege on her promise. This argument has been suggested as an important reason for the big law firms to employ tournaments (Galanter and Palay 1990).

Problems of Tournaments

These potentially positive effects of tournaments are diluted by the various problems that tournaments meet (or would meet) in practice. Even in the large private firms, the first application of tournament theory, promotions are governed in many heterogeneous ways that do not fully comply with the tournament model (Gibbs 1994). A similar statement has been made for large US law firms (Wilkins and Gulati 1998).

Many of the assumptions of the tournament idea are not and cannot be fully met. For example, the rate of winners cannot be specified in advance in judicial hierarchies because the vacancies are often determined by the case load, organizational demography, and public budgets. Hence, there is clearly no commitment to a tournament in judicial hierarchies. Similarly, the assumption that competitors do not know each other's performance is hardly met in practice, which in turn reduces the incentive effect.

A number of important problems concern the measurement of output. Competition for promotions can only incentivize and select efficiently if output is measured appropriately. For example, in response to suggesting a tournament of judges for the Supreme Court, it has been argued that output measures referring to the publication and influence of decisions do not fully capture the "virtue" of a good judge (Solum 2004) and are plagued

with inaccuracy (Levy et al. 2010). Similar concerns have been raised with regard to measuring the productivity of associates in law firms (Wilkins and Gulati 1998).

Conclusion

Tournament theory offers an interesting perspective on the competitions between lawyers in large law firms and between judges in judicial hierarchies. The theory predicts that lawyers and judges may sometimes engage in a rat race and that the winners tend to be better than the losers in measured dimensions of productivity. However, the assumptions of a pure rank-order tournament are never fully met in real law firms and real judiciaries. Therefore, tournament theory should not be taken as a descriptive or prescriptive “model” but rather a “metaphor” to help understand empirical patterns (Wilkins and Gulati 1998).

Traceability

Christophe Charlier

Department of Economics, Université Côte d’Azur CNRS, GREDEG, Nice, France

Definition

“The ability to trace the history, application or location of an entity by means of recorded identifications” in “ISO 8402:1994 Quality management and quality assurance – Vocabulary.”

Introduction

A general definition of traceability is found in “ISO 8402:1994 Quality management and quality assurance – Vocabulary” as “The ability to trace the history, application or location of an entity by means of recorded identifications.” Traceability is a typical example of a voluntary management practice that predated food safety regulation that ends up entering sanitary public policy. Voluntarily used at the beginning by few operators in high-quality food chains only, traceability has become a mandatory risk management practice for all food operators in Europe. However, legal forms (voluntary vs. mandatory), as well as exigencies of the various traceability systems implemented

around the world, remain very different, even for a same product (e.g., see Schroeder and Tonsor 2012 for bovine traceability).

Traceability is considered from two broad perspectives in economic literature. First, it has been analyzed from firms' standpoint. The determinants of traceability adoption have been explored in this field. The link between traceability adoption and firm characteristics such as their complexity, their hierarchical structure, and the kind of relations they have with downstream suppliers has been put forward (Galliano and Orozco 2011, 2013). The aim of operating under a private standard (that requires traceability) or under a quality label such as a geographical indication has also been presented as an important adoption determinant (Souza Monteiro and Caswell 2009).

Second, traceability has been analyzed from the social standpoint. This part of the literature is driven by the aim of establishing economic rationale for traceability. Whether mandatory or not, traceability is justified by information asymmetry among food business operators along the food chain and among food producers and consumers. This information problem arises because of the "credence good" attribute of food safety or quality. As the nature of this information problem is multidimensional, traceability may be more or less demanding. The economic literature agrees with the idea that traceability may be defined according to three characteristics (Golan et al. 2004): its breadth, defined as the amount of information delivered by the system (i.e., the variety of the items recorded); its depth, characterized by how far back in the supply chain information record is made; and its precision, generated by the tracking unit used. Depending on the "values" chosen for these characteristics, different traceability systems are used.

Whatever its form, traceability cannot in itself insure food safety or food quality. It only gives information. However, by delivering information, traceability performs three functions that impact on food safety (Hobbs 2004) and the way food safety crisis may be managed. First, the possibility of tracking back the origin of food through the supply chain allows for ex post efficient management of food safety crisis (withdrawal of unsafe

products from the supply chain) and implies cost reduction as a consequence (health cost, lost productivity, lower product sales, etc.). Second, breaking points along the supply chain and responsible operators are more easily identifiable with traceability, so that liability can be established. Operators are therefore more inclined to comply with regulatory standards. Finally, when coupled with labeling, traceability may convey information to consumers on quality or safety attributes. These links between traceability and food safety may seem obvious. However, in the aftermath of the bovine spongiform encephalopathy crisis, when traceability emerged as a risk management tool, they were debated in the Committee on General Principles of the Codex Alimentarius. Unsurprisingly, traceability has not entered national food safety legislations in the same way. For example, traceability has remained limited to certain products in the USA, whereas it has become mandatory for all food and foodstuff in the EU.

This entry considers the literature dealing with the "social standpoint" on traceability. It first focuses on the European Regulation making traceability mandatory. It then examines voluntary traceability through the two main economic reasons previously underlined: incentives and liability concerns.

Mandatory Versus Voluntary Traceability

The Regulation (EC) No. 178/2002 considers traceability as a risk management tool enabling "accurate and targeted withdrawal" of products from the food chain. The Regulation has a broad scope of application since every stage of the food chain is concerned, demanding that all food products and foodstuffs must be tracked. Breadth and depth of such a system are therefore maximal. However, the Regulation only requires operators to be able to identify "the business from which the food, feed, animal or substance that may be incorporated into food or feed has been supplied." Furthermore, no requirement on batch formation appears. The text implicitly favors a formation of

batches according to the identity to whom the products are sold without taking into account their homogeneity in terms of their inputs' origins. The precision of the mandatory traceability implemented is thus very weak. Charlier and Valceschini (2008) show that with these characteristics, the traceability is constructed "step by step" without requiring a compilation of data that would grow along the food supply chain until the good is sold in the market. The authors show that this traceability system alone may hardly reach the goal assigned by the regulation of a targeted withdrawal of products mainly because of the lack of discipline on the products' batch formation.

Together with traceability, the Regulation (EC) No. 178/2002 stipulates operator's responsibilities on food safety procedures concerning food withdrawal and obligations to inform and cooperate with public authorities in case of a sanitary disruption. Interestingly, these obligations and the proactive behavior required on product withdrawal call for a more stringent traceability than the mandatory one. The implementation of this traceability is therefore implicitly left to operators that have to coordinate their efforts (adopting common rules on the constitution of batches) so that the traceability system adopted by downstream operators does not scramble information produced by traceability efforts of upstream operators (Charlier and Valceschini 2008). This individual choice to implement stricter traceability responds to incentives created by regulatory disposition on operator's responsibilities. Not surprisingly, incentives and liability have been found in the economic literature as the two main drivers for voluntary adoption of traceability.

Incentives and Liability

A significant part of the literature has dealt with traceability through the lens of incentives. In this field, an important characteristic of traceability is that this information system allows allocating the cost of food safety failures to the responsible parties. To do so, traceability is always implemented jointly with another device (e.g., inspection procedures) allowing detecting

food safety failures (Starbird and Amanor-Boadu 2006, 2007). Relations among suppliers and buyers of foodstuff are seen as taking place in context of asymmetric information and are generally represented using a principal-agent framework (Resende-Filho and Buhr 2008). The models developed delineate the conditions under which traceability provides incentives to suppliers to deliver safe products. The results depend crucially on various variables such as the food safety failure cost, the production cost of a safe product, the inspection cost, and the cost of allocating failure responsibility. Traceability in this context may be modeled differently. It may be characterized by a "cost allocation factor," i.e., "the proportion of food safety failure costs that can be allocated to the producer responsible for unsafe food" (Starbird and Amanor-Boadu 2007), or by the "probability of finding the source of a problem" (Resende-Filho and Hurley 2012). This cost (or this probability) is an exogenous variable. When traceability is mandatory, it thus depends on policy makers' decisions.

The two main messages of this literature are first that traceability is not unambiguous for food safety since precision in tracking foodstuff and incentive payments in contracts are substitute (Resende-Filho and Hurley 2012) or because incentives to choose contracts selecting safe producers not only depend on the cost allocation factor but also on the importance of the failure costs (Starbird and Amanor-Boadu 2007). Second, depending on the values observed for the various other variables influencing incentives to deliver safe products, policy makers should choose adequate values for traceability.

This ambiguity is also found when incentives come from industry reputation preservation rather than the allocation of the cost of food safety failures. Indeed, when traceability enhances food safety along the food chain, food safety reputation for the industry is created. However, this reputation is a fragile asset and is highly sensible to food safety failures and publicized product recalls. A very localized disruption may disturb the entire food chain if the product withdrawal cannot be targeted. In such a context, traceability allowing targeted and rapid product withdrawal may be

seen as protecting the reputation of the food chain and its profits (Pouliot and Sumners 2013). However, this result on profits presupposes that demand reaction to food safety failures is strong. If this assumption is relaxed, targeted withdrawals of product have the effect of increasing price to which products remaining on the market are sold. This situation benefits to some suppliers thus less inclined to collectively engage in traceability. At an individual level, the expected revenue may be a decreasing function of food safety reached at the industry level (Pouliot and Sumners 2013).

The consideration of liability appears in articles in line with the previous ones dealing with incentives. In a food chain composed of farms, marketers, and consumers, liability incentives are enhanced by traceability and result in higher food safety level (Pouliot and Sumners 2008). Traceability from marketers to farms does not alter marketer's liability but allows the former to impose costs of food safety failures on the latter. The incentives for delivering safe products thus created by traceability increase consumers' willingness to pay for the foodstuff. Indeed, they consume safer food and are more likely compensated in case of a food safety problem. This behavior results in higher incentives to produce safe food for the entire food chain. However, as the industry size (i.e., the number of operators) increases, free-riding behaviors appear. Operators realize that the impact of their investment in food safety on the global food safety is decreasing. As a corollary, the "concentration" of the supply chain would positively impact on food safety. For a given size of a food chain, the larger are the different operators (i.e., the less numerous they are at each step), the less likely is free riding in food safety investment (Pouliot and Sumners 2008).

Discussion

In light of the preceding developments, voluntary traceability clearly raises a coordination issue among the different operators of a same food chain that has the potential to reframe the supply chain. Very few studies have tackled this problem

that may constitute an important theme for future research. Banterle and Stranieri (2008) show, for example, that voluntary traceability increases vertical coordination among firms. As both product quality and characteristics of the processes may be tracked (especially within a private standard framework), diverging views among upstream and downstream operators on the kind of traceability that should be implemented through the chain may emerge and have to be resolved. Therefore, the weight of operators, their strategic position within the supply chain, and their capacity to coordinate at a given step of the food chain to face other operators may be seen as central elements for the kind of traceability finally implemented. If food safety objective remains central in this coordination, other economic motives may be at stake and need to be analyzed.

Trade Secrets Law

Luigi Alberto Franzoni
University of Bologna, Bologna, Italy

Abstract

Standardization of trade secrets protection was one of the goals of the TRIPs Agreement of 1998. Still, substantial differences across jurisdictions remain. In defining the optimal scope of trade secrets law, lawmakers should consider that strong protection is likely to promote inventiveness but also to retard the diffusion of knowledge and stymie competition.

Definition

Trade secrets law protects firms from unauthorized disclosure of valuable information.

The misappropriation of trade secrets generally constitutes an act of unfair competition that triggers civil liability and, possibly, criminal penalties. Standard examples of misappropriation include espionage, breach of nondisclosure agreements, and unauthorized revelation to third parties.

Historically, trade secrets law has its roots in the Middle Ages, in a time when craft guilds jealously protected their specialized knowledge (the “mysteries” of the arts). Within the guild, as well as in master-apprentice relationships, secrecy was the standard, and its violation could be sanctioned with the capital penalty (see Epstein 1998). In modern times, violation of secrecy has been regarded as an act of unfair competition contrasting with the honest practices that should prevail in the business community. Unfair competition was mentioned in the *Paris Convention for the Protection of Industrial Property* of 1883 (art. 10bis), although with no direct reference to the misappropriation of trade secrets. In spite of the convention, huge differences across countries characterize the field of unfair competition law (see De Vrey 2006; Henning-Bodewig 2013).

Commercial and technological information can leak out of firms in many ways:

It can be stolen by employees or third parties (as in the case of information embodied in documents, files, or technological items); it can be obtained by means of subtle espionage techniques (tapping, dumpster diving, etc.); it can be disclosed to third parties by unfaithful employees; it can be memorized and taken away by former employees who start their own business; it can be indirectly devised by competitors by means of reverse engineering; it can be obtained from the scrutiny of documents submitted to regulatory agencies; it can be obtained by rivals by communication with parties related to the information owner (e.g., buyers and suppliers).

The main function of trade secrets law is to clearly tell methods for the acquisition of information that are admitted from those that are not. Those that are not constitute acts of “unfair

competition” and lead to civil and criminal liability. Given the multitude of ways in which commercial and technological information can spill from firms to the others, in most countries trade secrets law provisions are scattered across several branches of the law, including tort law, contract law, intellectual property (IP) law, labor law, and criminal law. On this account, substantial variations exist across legal systems (see European Commission 2013).

At international level, an important definition of trade secrets is provided by the TRIPs Agreement (art. 39.2), which postulates that lawfully acquired business information qualifies as a trade secret only if it (a) is secret, (b) has commercial value because it is secret, and (c) has been subject to reasonable steps to keep it secret. From this definition, we learn that publicly available information and everyday knowledge are not eligible for legal protection; valueless information and information not subject to reasonable protection do not qualify as trade secrets. All countries belonging to the WTO should make sure that legal protection is granted to trade secrets against acts of misappropriation which include “breach of contract, breach of confidence, and inducement to breach” (TRIPs, footnote 10). The task to define the precise set of activities falling under the “misappropriation” category lies with individual countries, which might be more or less strict on this account. In turn, misappropriation leads to remedies that usually include injunctive relief and damage awards. The latter are typically commensurate with the actual loss to the trade secret owner or the unjust enrichment of the party that has misappropriated the secret. In most countries, courts can also set a reasonable royalty for the use of the secret (for a limited time span).

From a policy perspective, the main issue raised by trade secrets law is the optimal scope of the protection granted to the owners of undisclosed information (which conducts are forbidden and which are not). Some polar conducts can easily be categorized: the theft of documents is undoubtedly unlawful, while reverse engineering tends to be lawful everywhere. With respect to other conducts, courts and lawmakers offer a variety of positions. For example, courts and

lawmakers can be more or less lenient with respect to key employees who leave their company to work for a competitor. In some jurisdictions, this conduct can lead to an unfair competition suit, under the doctrine of inevitable disclosure. In some other jurisdictions, e.g., in California, workers’ mobility finds little impediments in trade secrets law (see Gilson 1999). In deciding the strength of trade secrets protection, lawmakers need to keep in mind that strong protection comes at the cost of reduced labor mobility and lower diffusion of technological knowledge (see Fosfuri and Rønde 2004).

More generally, trade secrets law has been credited with the following beneficial effect (see Lemley 2011). First, by preventing unwarranted diffusion of valuable information, trade secrets law provides a competitive edge to the original producer of the information. With respect to innovative knowledge, for instance, the head start advantage provided by secrecy is regarded as important by most companies (see Cohen et al. 2000). Second, trade secrets law allows firms to reduce the self-protection expenditure: thanks to the legal obstacles against unwanted disclosure, firms can more freely organize their units and share information across their members (see Rønde 2001). In the absence of legal protection, costly measures would have to be taken to reduce the probability of leakage. In fact, reduction of self-protection expenditure is the main function that Landes and Posner (2003) credit to IP law. Facilitated information sharing can also concern contracting parties outside the firm. Effective enforcement of nondisclosure agreements facilitates the transmission and sale of information from the producer to third parties. In this sense, nondisclosure agreements represent a partial solution to Arrow’s information paradox (Arrow 1962), which postulates the unavailability of restitutory remedies for unwarranted information disclosure (once shared, information cannot be returned).

At the same time, trade secrets law also produces social costs. First, by limiting the circulation of information, trade secrets law may retard imitation and stymie technological progress. It has been noted, in fact, that strong technological

spillover characterizes some fast-evolving technological districts like the Silicon Valley, where high levels of labor mobility speed up the diffusion of innovative knowledge (Saxenian 1996). Information sharing facilitates the expansion of the stock of public knowledge, giving birth to new forms of collective invention (Allen 1983; von Hippel and von Krogh 2011).

A further cost brought about by trade secrets law concerns the relationship between secrecy and patent protection (explored, more generally, by Hall et al. 2014). If trade secrets law is strong, inventors have weaker incentives to rely on the patent system. Hence, fewer inventions are disclosed in the patent applications and the stock of public knowledge may advance less rapidly. Here, the issue is whether patents or trade secrecy are better protection tools from a social point of view. Patents have limited duration (normally 20 years) and require disclosure of the invention. Trade secrets can potentially last forever and, by definition, are not disclosed. This implies that either nobody has access to the information – and the original owner retains market power forever – or that third parties have to waste resources to rediscover that original invention (for the purpose to market it directly or to improve upon it). The comparison between the two forms of protection hinges on the nature of the innovation process (how many firms have the capacity to come up with the original invention, the extent of the research spillovers) and the nature of competition across firms upon duplication (under trade secrecy) (see Denicolò and Franzoni 2012).

The impact of trade secrets law on the propensity to patent, however, should not be overestimated. In fact, the subject matter of trade secrets law is infinitely broader than that of patent law. This is because nearly any type of commercial and technological information is eligible for trade secrets protection, while only inventions that meet the originality and non-obviousness requirements qualify for patent protection. A recent investigation by Hall et al. (2013) reveals that only 5% of innovative UK firms rely on the patent system. All of them, one way or another, rely on secrecy.

Trademark Dilution

Giovanni Battista Ramello
DiGSPES, University of Eastern Piedmont,
Alessandria, Italy
IEL, Torino, Italy

Definition

A trademark dilution claim is raised whenever a new trademark, albeit it does not confuse consumers, produces detriment to the distinctive character of another trademark. Then the use of new trademark, although used in a noncompeting market, can still be forbidden because it weakens the distinctiveness of the already existing trademark.

Main Characteristics

Trademark dilution is a special kind of infringement that does not involve a direct violation, but it is rather a theoretically legitimate behavior that can nevertheless compromise the distinguishing effect of a given trademark (Economides 1998). It is forbidden by recently amended laws, and it is generally raised in the case of so-called famous or strong trademarks. Antidilution measures essentially enshrine the accomplished transformation of

trademark into a property right over a sign and its semantic sphere (Beebe 2004; Ramello 2006). More precisely the goal of antidilution clauses is no longer to protect the informational value of the trademark and avoid consumer confusion, for which the existing regulations were sufficient, but rather to punish behaviors that may indirectly encroach upon this newly forged semantic sphere and its economic exploitation (Landes and Posner 2003). The dilution claim is generally raised whenever a trademark – even if it does not confuse consumers – produces “detriment to the distinctive character” of another famous mark (*Adidas-Salomon AG v. Fitnessworld Trading Ltd.*, 2003, 1 C.M.L.R. 14) according to European law, or results in “lessening of the capacity of a famous mark to identify goods and services” according to US law (Lanham Act, Section 43c, 15 USC Section 112). The main idea is that the use of a sign somehow linkable to a famous one in a noncompeting market can still be forbidden because it weakens the distinctiveness (and most importantly the differentiation effect) of the famous mark. This can happen by “tarnishment” if applied to inferior-quality goods that might lower consumers’ opinion of the famous mark, or by “blurring” when there is a sort of semantic free-riding, so that the new sign does not confuse the consumer but still indirectly exploits, and thereby impoverishes, the distinctiveness of the famous mark (Lunney 1999).

The general legislative principle that emerges is thus to preserve the semantic capital of a given trademark, in the market and the minds of consumers, by the difficult route of defining property boundaries in the semantic sphere (Ramello and Silva 2006). Such a solution requires directly protecting the signified through a new intellectual property right that extends beyond the tangible market to cover the market for meanings (Ramello 2013). By so doing, the law protects firms’ investments in creating new semiotic products and confirms the altered function of the trademark, which now assigns a legal and economic monopoly over a broad relation between signifier and signified (Ramello and Silva 2006).

The enactment of antidilution measures, after being pushed back several times, was ultimately achieved through protracted lobbying efforts although some scholars expressively speak of “doctrinal puzzlement” (McCarthy 2004) and of “the death of common sense” (Lemley 1999). However, besides these criticisms, the antidilutions measures mark the metamorphosis of trademark, born as an informational tool originally intended as an adjunct to the market for safeguarding consumers, into a property right over a sign and its semantic sphere (McClure 1996). In the meanwhile, it marks the “divorce” of trademarks from the goods they are supposed to represent, which in fact heralds their own “modification” (Lemley 1999).

Trademarks and the Economic Dimensions of Trademark Law in Europe and Beyond

P. Sean Morris

Faculty of Law, University of Helsinki, Helsinki, Finland

Abstract

The economic analysis of trademark law continues to draw a number of commentaries, yet more and more, the courts are not factoring concrete economic analysis of trademark law and trademark protection in their decisions. In this entry I give an overview and status of trademarks from a law and economic perspective and suggest that trademark laws need to respond to the economic dimension that occurs on the market and consumer economic behaviour.

Introduction

Trademarks are signs that communicate the economic interest of goods manufacturers or service providers to customers with valuable information to influence their purchasing behavior. Signs which constitutes a trademark are capable of graphical representation, in particular words, letters, numbers, shape of goods, or their packaging, in as much, such signs can distinguish the goods and services of different providers. Thus, one of the underlying functions of a trademark is to provide information about source and origin of goods and services. A trademark is granted and regulated under the trademark laws applicable to the territory, national or *supra-federal*, for which it is applied, and examples of supra-federal trademark legislations are the *Trade Mark Directive* (TMD 2008) in Europe or the *Community Trade Mark Regulation* (CTMR 2009) both of which are for trademark regulation and harmonization in the European Union (EU).

A Federal trademark legislation is, for example, the *Lanham Act* in the United States America

(USA), while a national trademark legislation is, for example, the *Trade Marks Act 1994* in the United Kingdom (UK) or the Swedish Trademark Act (2010: 1877). These acts together constitute the legal regulation for trademarks in their respective territories, although the EU's *supra-federal* TMD and national trademark laws coexist for the harmonization of trademark law throughout the EU's internal market. In the USA, the passage of the *Lanham Act* in 1946 saw the US trademark law as "harmonized" so to speak. The situation in the EU is somewhat different given that the road to harmonization of European trademark law has only been a recent phenomenon with the first TMD of 1989 and revisions in 2008 and 2014. A new trademark directive and trademark regulation in the European Union came into force in January and March 2016 respectively.

Trademarks in Law and Economics

In cases such as *Intel v CPM*, the European Union Court of Justice (EUCJ) introduced the notion of consumer *economic behavior* in the context of European trademark jurisprudence. The recognition by the Court of a change in the economic behavior of consumers was arguably an overt acknowledgement of the role of economic analysis of trademarks. Trademarks as a branch of intellectual property rights have always been the gatekeeper of how businesses function in a competitive economy, and, as the face of goods, products, and services, trademarks' economic functions and regulation are essential to both the rights holder and how competitors enter the market.

Because trademarks are signs that represent the economic identity of goods and services and, in this regard, they serve as the bridge that links customers' economic behaviors to the proprietor of goods and services, then trademarks are arguably the most important aspect of intellectual property rights in a market economy because unlike other regimes such as patents and copyrights, a trademark, albeit with renewals, is essentially perpetual and generally outlives the initial rights holder(s). This perpetual nature of

trademarks demonstrates that they are important in how goods, products, and services are placed on the market to guarantee fair trade among the many players that operate in a dynamic market. A dynamic market will always allow flexibility in trademark use through licensing or other methods for trademark owners to encourage fair competition.

But another dynamism of the market is the economic behavior of trademarks, and perhaps it was no surprise that the EUCJ in *Intel v CPM* overtly calls for the economic analysis of trademarks when trademark infringement claims are made. That decision concerned changes in the economic behavior of the average European consumer and how such changes could cause damage to a reputable trademark. This concern by the EUCJ highlights the need for more understanding of the economic dimensions of trademark law and the *real* functions of trademarks in a market economy and its impact on the economic welfare of consumers.

Although the courts sporadically address the law and economic approaches to trademarks, there has long been a growing body of literature that discusses trademarks in a law and economic context. Some of the early scholars that applied law and economics approaches to trademarks include Chamberlin (1933) and Robinson (1933) when their theories of imperfect competition are factored in and, in particular, Chamberlin's reference to "product differentiation," while other scholars (Papandreou 1956; Brown 1948; Mueller 1968) also offered their perspectives on the economics of trademarks. But some of the major works on the economic analysis of trademark law emerged in the late 1980s with those by Landes and Posner (1987) and Economides (1988) and then other contributions by scholars such as Lunney (1999), Ramello (2006), Barnes (2006), and Griffiths (2011).

These approaches to the economic dimension of trademark law incorporate the economic analysis of law. Arguably, the study of law and economics of trademark law began with the great transformation in the study of law and economics as a whole that had roots in the USA at the turn of the twentieth century. Legal luminaries such as

Holmes (1897) helped to sound the trumpet for the law and economic approach when he observed that “the man of statistics and the master of economics” were ideally good tools for the law.

The Chicago School has long been seen as the driving force behind the study of law and economics in the twentieth century with renowned economists in the 1940s and 1950s that gradually built upon *Marshallian* (1890) price theory or other *canons* such as Knight (1933). But the true form of law and economics only took off in the 1960s where economists such as Stigler (1961), Director (1964), and Coase (1960) oversaw the ascent of Chicago approaches to law and economics. Stigler (1961) played an essential role in the development of law and economics of trademarks when he developed a model of optimal consumer search behavior under which advertising reduces consumers’ search costs.

There are critics of the 1960s development of law and economics under the auspices of the Chicago School, and some have even argued that the study of law and economics is rather old given that “the study of the interrelations between legal and economic progress is as old as economics itself” (Medema 2010, p. 160). But even if the origins of law and economics can be disputed, there is without a doubt that the modern phenomena that we understand today as law and economics are essentially a phenomenon that gradually developed as the Chicago School of thought in the USA blossomed in the 1960s and 1970s, even to the point where “lemons” (problems with post-sale used cars) were used to analogize information symmetry (Akerlof 1970) or, in trademark terms, the rights holder have a better idea of the quality his mark represents.

By the 1970s, other Chicagoans such as Posner had also emerged fully in his own right applying economic analyses of the law (Posner 1973), and in 1987 he produced with a colleague a seminal article that reflects similar arguments raised in Stigler’s information advertising paper (1961). The economics of advertising, as per Stigler and the search theory, essentially served as the launch pad for economic analyses of trademarks and arguably because of information that advertising portrays in particular communicating the

trademark to the consumer, even if contemporary scholars believe that “advertising is patently uninformative” (Jordan and Rubin 2008, p. 19). As a result of the broader study of law and economics, the Chicago approach was transposed to a number of other areas such as tax law, antitrust law, criminal law, contract law, and tort law, among others (Cooter and Ulen 2012; Miceli 1997). The law and economics approach gradually moved on to the study of intellectual property rights which covered mainly patents, copyrights, and much later trademarks, and in a 1987 joint paper by Landes and Posner, the law and economics approach was applied to trademark law and to revolutionize the study of trademarks and trademark law in an economic context.

Landes and Posner (1987) in their seminal article which nowadays stands as the cornerstone on the economic analysis of trademark law have argued that a trademark’s essential function from an economic perspective is to reduce consumer search costs. Their arguments are steeped in the Chicago School of economic tradition, in particular, what I think was a reflection of Stigler’s 1961 paper on the economics of information.

An earlier paper dealing with the economics of information, albeit from a legal perspective, also discussed advertising, which broadly encompasses trademarks (Brown 1948); however, this was prior to full development of the Chicago School. Economides (1988) who offered a purely positive economic theory on the economic analysis of trademarks noted in particular that trademarks can serve as a barrier to entry since the trademark “can also serve to increase welfare through the reduction of an excess number of brands” (Economides, p. 536). This approach, and like many others, that offers an economic perspective falls within microeconomic theory that concerns how individuals make rational decisions (behavioral theory), and it is largely responsible for economic analysis of law and by extent trademark law. The approach in the literature that covers the economic analysis of trademark law has essentially still kept at the forefront the problems of trademarks in the competitive economic space of society in their dual role to promote competition and to reduce consumer search costs.

Trademark Monopolies and Economic Effects

In regulatory instruments such as the CTMR, it is explicitly noted in its recitals the desirability to promote “harmonious development of economic activities” using trademarks. In this context, there is an economic rationale for trademark law since quality and origin suggest an economic incentive for the trademark owner while giving assurances to consumers. In this regard, trademark law is the principal arbiter that protects consumers in their economic decision-making when shopping for goods that are protected under trademark law. Yet, it is those very same trademark laws that also give the trademark owner a monopoly lease to use a specific mark to designate his goods or services. The guarantees that the law provides for trademark owners include a right to prevent others from using the mark and also a *right* to enhance the creative and innovative process in a broad sense.

The argument that trademarks are monopolies is not entirely new and has been around for ages, for example, in the English case *Blanchard v Hill* (1742), trademarks were identified as “one of those monopolies.” What this means, even in contemporary times, is that the exclusivity and absoluteness of trademarks make them one of those monopolies that are subjected to being abused in an anticompetitive way and affect how consumer spending decisions are made. As monopolies, the welfare effect on consumers are negative since their spending powers are dictated by the trademark that they are locked onto, which in turn creates monopoly profits for the trademark owner who has the ability to influence the purchasing habit of the consumer. Furthermore, as a branch of intellectual property rights, trademarks are generally seen through the lens of state-granted monopolies, and the literature that emerged over the last six decades or so generally paints trademarks as monopolies (Lunney 1999).

In a number of ways, trademarks create problems on both the market and for the consumer. For consumers the problem of trademark monopolies is that, contrary to reducing search costs, trademarks lock consumers in *perpetuity* – whereas consumers are loyal only to the manufacturers of

the goods the trademark represents. Arguably then, consumer search costs are then limited since they do not engage in the option of the alternative and or at times (naively) assume the mark to which they are loyal represents quality. However, on occasions, consumers may find alternatives that allow them to be better off. For the market, the monopoly in trademarks erects barriers to entry for new goods on the market. This barrier to entry, in particular contemporary times, can arise from an abundance of registered trademarks that are not in use or competitors unwilling to license a mark to new entrant that will compete with them on the market. These observations highlight the gray zone in which trademarks must operate catering to the consumer and the rights holder.

However, the legal reality of trademarks’ economic effects is perhaps those that are articulated by the Courts since the Courts themselves help to shape the economic activity of markets. In *Qualitex Co. v Jacobson*, a US court was perhaps eager to formally recognize the economic dimension of trademarks and the law when it noted that consumers were essentially rational decision-makers because trademarks allow them to make better purchasing decisions and reduce their search costs (*Qualitex Co. v Jacobson*, 163–164). In Europe, where the harmonization of trademark law is an integral part of the EU’s internal market, the EUCJ has often echoed the economic dimension of trademarks, such as in *Intel v CPM* where it observed the possibility of change in economic behavior due to trademark use.

Perhaps the EUCJ’s more broad reading of the economic dimension of trademark protection and use was in *L’Oreal v Bellure* where the Court spoke of trademark’s investment function. This (additional) interpretation of trademark functions suggests the wide economic value of trademarks and the role trademarks play in a fully integrated and free market. The value of a company’s trademark is often the most important piece of asset that a company holds and can leverage with either for investments or loans in the company. The *L’Oreal v Bellure* Court was indeed right when it pointed out the investment function of trademarks

because the value in a trademark is built over time due to the actual investments in a trademark such as advertising or the reputation that the mark earned. As a valuable asset within a company's portfolio trademarks plays an integral investment function (even if *L'Oreal v Bellure*) did not have this reasoning in mind. The implication here is that the economic function of a trademark goes beyond quality and source function but to that of economic value represented by, a form of *inter-* and *intra-*investments which are acquired over time, thereby creating a market for "goodwill."

But despite the inherent monopoly in trademarks, it is the consumer that benefits the most from trademarking activities since the investment function that trademark performs contains a positive spillover when there is increase in trademarking activities. This spillover is the promotion of more competition and the ability of consumers to rationally select goods that are based on their purchasing power. The trademark would normally signal this and influences how the consumer behaves. In dynamic markets such as the EU where national trademarks operate alongside *European* trademarks, consumers respond differently to *external* trademarks that are not well known or where such trademark does not send quality signal. Therefore, consumers can sometimes be suspicious of goods with unknown reputation that originates in a different country. Another factor that also influences consumer economic behavior toward internal and external trademarks in the EU is that of national consciousness and pricing. Even where a trademark signals quality in a reputable good and a new entrant uses a similar trademark to compete, the Courts have cautioned that only a change in consumer's economic behavior could harm the reputable mark. In *Intel v CPM*, the EUCJ introduced the concept of economic behavior in the trademark *lingua*, suggesting the wider role of economic analyses of trademark law and behavioral patterns of consumers:

the use of the later mark is or would be detrimental to the distinctive character of the earlier mark requires evidence of a change in the economic behaviour of the average consumer of the goods or services for which the earlier mark was registered

and consequent on the use of the later mark, or a serious likelihood that such a change will occur in the future. (*Intel v CPM*, para. 77)

From an economic point of view, the Court cautiously warns that economic changes can affect trademark use and protection. The reasoning by the EUCJ that only a change in the economic behavior of the average consumer could threaten Intel's – INTEL mark if those consumers flock to CPM's – INTELMARK trademark broadens the scope for economic analyses of trademark use and protection and how economic evidence is assessed within the confines of the law. Intel did not provide any (economic) evidence that CPM's INTELMARK was causing harm to its economic activities, and therefore the Court found no reason that Intel's mark was being threatened.

Perhaps one of the wider implications of the *Intel v CPM* ruling by the EUCJ and its notion of change in economic behavior in the average consumer is to look to the broader economic theory of public goods and how that is related to trademark law. Given that Intel's mark is a reputable mark, there is no doubt that it creates positive externalities and therefore a magnet for competitors to free ride on. Trademarks are in a sense - public goods - and therefore an opportunity for competitors to free ride on the good will of reputable marks. In other words, information is a public good, even when embedded in a trademark. Barnes (2006) has similarly argued that trademark owners are information creators and such information is widely available for "all people to use" and hence, arguably is a public good. For trademark law, the implication is even grave, given that, as Barnes (2007) observed, both dynamic allocative efficiency and static allocative efficiency may emerge.

Because trademark protection in Europe and globally is expanding, there is an urgent need to factor in empirical evidence based on the economic behavioral patterns of consumers in trademark litigations that can be used to help the Courts arrive at conclusions that are based on economic theories. Such empirical evidence should go beyond the mere surveys that are often used in

trademark litigation given that excessive trademarks are “goods in their own right” (*Plasticolor v Ford*, 1989, 1332). It is also useful, when discussing economic approaches of trademark law to consider other areas competition law. This is because empirical evidence suggests that trademarks are anticompetitive, for example, by serving as tying products (Smirti 1976) or due to their inherent exclusivity or market power (Morris 2012, 2013), and whether such exclusivity is being abused by trademark owners.

The market economies in which trademarks exist are expanding, and the movement of global commerce has put into sharp focus trademark use and protection and the scope of trademark law. In trademark legislations, whether international instruments such as the Trade-Related Aspects of Intellectual Property Rights (TRIPS), regional harmonization efforts at the EU, and national trademark laws, there is the need to factor in “economic effects” of those laws and how they relate to other areas of regulation in the free market.

Trademarks are no longer seen as *ought* to be protected but rather how to assess the economic impact of trademarks that are currently protected and are in use and what are the economic causes of trademark nonuse. The economic impact of trademarks that are in use drives consumer economic behavior and how the markets respond to any perceivable changes in economic behavior, and this warrants fresh approaches to the economic dimension of trademark law.

Such economic dimension should move into a new direction beyond the predominant function (s) of trademark theory such as the search cost theory or the origin source theory. This new direction may take on, for example, the reduction of barriers to entry by allowing greater flexibility in the use of trademarks by competitors, or how the economic impact of product differentiation in trademarks affects the normative process in which trademarks must operate.

Ultimately, it is the trademark laws that can respond to the normative process, and perhaps, similar to the EUCJ’s recognition of change of economic behavior by the average consumer (also echoed in *Environmental Manufacturing v OHIM*, 2013), trademark laws, both in Europe and

beyond, can begin to reform by responding to changes in the market economy which ultimately leads to greater efficiency in the competitive process for the creation of wealth. Nevertheless, the change of economic behavior test that the European Courts advocate holds interesting interpretation for the economic analyses of trademark law both in Europe and beyond, since this new direction in trademark law interpretation has raised the threshold for trademark infringement analysis.

Traffic Lights Violations

Laurent Carnis

University Paris Est and IFSTTAR, Noisy-le-Grand, France

Abstract

Traffic light running is a violation of Highway Code that endangers the offender as well as other road users. The consequences of crash risk induced by this reckless behavior can be interpreted as a social cost and call for public intervention. Several tools are available for policy makers to enforce traffic light obedience. However, the cost of public intervention must be in line with the social cost of violations.

Although there is a sizable literature dealing with traffic light running, researchers generally focus on the predictors of such behavior and the impact of the countermeasures. This entry presents a literature overview from an economic perspective and proposes an economic analysis of traffic light violations and their regulation.

Synonyms

Traffic light violation

The author thanks E. Kemel for comments and suggestions on a previous version. The usual caveat applies.

Introduction

Red light running (RLR) is a violation of traffic rules that endangers the offender as well as other road users. A red light isolation is established when a driver fails to stop at a red signal indication. The crash risk induced by this reckless behavior calls for public intervention. Indeed, RLR can be considered as an external effect imposed upon road crash victims. A social cost is associated with this illegal behavior. The existence of this external effect finds its origin in the fact that the road is used as a common. Several tools are available for policy makers to internalize those costly consequences and enforce traffic light obedience.

Although there is a sizable scientific literature dealing with RLR, researchers generally focus on the predictors of such behavior and the impact of the countermeasures from an engineering and psychological perspective. The economic approach is quite inexistent, so that it is impossible to determine the appropriate intervention and be insured the public policy is efficient. It neglects also the economic dimension of driver's choice. This entry proposes an economic approach which provides a new perspective for this issue and gives an account of the specialized literature.

An economic approach is required because red light violation as an external effect calls for a public intervention. However, the cost of intervention has to be proportional to the social cost of violations. In other words, the cost element constitutes the crucial dimension not only for framing countermeasures but also for understanding the offender's choice.

The first section provides an economic explanation of the need for traffic light at intersection through a game theory approach emphasizing upon the needs of cooperation and fairness. The second section deals with an analysis of RLR from the driver's choice perspective. The consequences of RLR are identified in section "Consequences of Traffic Light Violations". Section "Regulation of Red Light Violations" reviews the available possibilities for enforcing this safety rule and regulating efficiently the RLRs through the economist's lens.

Signalized Intersections

Cooperation and Safety at Intersections

Without traffic regulation, the situation of two drivers reaching the intersection from opposite directions can be represented as a noncooperative game (Table 1). If both players stop, they suffer a time loss ($-t$); if they both go, they suffer a large loss related to a road crash ($-a$), with $a > t > 0$. If they make different choices, the stopping driver suffers the time loss, while the other driver breaks even. In this game, the Pareto optimum is reached when drivers take different strategies.

In that case, there is no dominant strategy. If the adverse driver is expected to stop (resp. go), the best decision is to go (resp. stop). The absence of unique equilibrium can lead to a suboptimal situation (the crash or the mutual stop). By forcing one driver to stop, traffic light can be considered as an exogenous intervention that imposes one Pareto optimal equilibrium. Then traffic light can find a justification from the economic perspective by making cooperation possible between drivers. Here a better cooperation is related with traffic safety.

Traffic Management: Fairness and Sustainable Cooperation

Different types of traffic regulation are possible for solving the coordination problem at intersection such as putting a stop sign or giving priority to the right. However, the two aforementioned solutions systematically give priority to the same users. For the sake of fairness and efficiency of traffic regulation, traffic light alternates the two equilibria. Drivers from the non-priority roads are not systematically penalized, and waiting time is shared between drivers coming from opposite direction. Thus, traffic light ensures fairness and reciprocity among users. It is an important feature.

Traffic Lights Violations, Table 1 Game matrix of drivers at intersection

Driver 1	Driver 2	
	Go	Stop
Go	$-a, -a$	$0, -t$
Stop	$-t, 0$	$-t, -t$

Indeed, fairness and reciprocity can motivate cooperative behavior (Fehr and Schmidt 2006) and can therefore contribute to driver obedience to this traffic rule. It also makes it a sustainable one.

Traffic management is another main objective of traffic light regulation. Traffic lights are sometimes used for ramp metering, in order to make new entrants wait during congested periods. Others are used for regulating speed in urban areas. Such regulation aims at producing a smoother and calmer traffic among the road users and avoiding congestion. A driver pays a limited period of waiting time in order to enjoy larger gains with a reduced total driving time. Although such traffic management tools aim at reducing road crashes and time wastes, and ultimately the related social costs, not all drivers always abide to these rules. In a sense, RL violation can be considered as a free riding activity. The free rider would like to benefit from traffic safety and management without participating to its funding by obeying the rule. It is also a departure from the Pareto optimal equilibrium defined previously.

Traffic Light Violations

Despite of the related crash risk, red light running (RLR) is not an uncommon event. Retting et al. (1998) observed an average of three violations per hour on two urban intersections in Arlington. Carnis and Kemel (2012) reported very similar results from a field investigation for 24 traffic lights in Nantes (France) and showed that RLR characteristics vary with the type of sites, users, and contexts.

Individual Choice

A RLR is mainly an individual choice. Indeed, the classical school of economics of crime assumes that traffic offenders choose whether to violate the law or not by following utility maximization rules (Becker 1968). For red light violation, the elements of this type of decision can be presented in a decision matrix (Table 2). Stopping at the traffic light results in a sure time loss ($-Ct$),

Traffic Lights Violations, Table 2 Matrix of go/stop individual decision at red light

	No enforcement	Enforcement	
	No crossing vehicle	No crossing vehicle	Crossing vehicle
Stop	$-Ct$	$-Ct$	$-Ct$
Go	0	Cf	$-Ca$

whereas the consequence of a red light violation is uncertain and event contingent. It depends on the presence of another vehicle crossing the intersection and enforcement (a police officer or camera). If one of these events occurs while the driver decided to run the light, a cost is suffered: ($-Ca$) for the crash cost and ($-Cf$) for the cost of a fine, with $Ca > Cf > Ct > 0$. Ca can also include a penalty for causing the crash by red light violation.

There is no dominant strategy and the decision depends on users' beliefs and preferences. Decision under uncertainty is classically modeled by expected utility. This model assumes that decision makers assign subjective probabilities to events and subjective utilities to consequences and choose the alternative that maximizes the mathematical expectation of their utility. Normalizing the utility with $U(0) = 0$, a driver is expected to run the light if $U(-Ct) < pf \times U(-Cf) + pa \times U(-Ca)$, where pf (resp. pa) is the subjective probability of being fined (resp. responsible of a road crash). RLR is thus expected to vary across individuals and contexts depending on attitudes and perceived risks. This framework predicts also that RLR decreases when Pf , Pa , Cf , or Ca increases or when Ct decreases.

Empirical studies bring evidence for most of these predictions. The literature shows that increasing detection probability (by the mean of red light cameras, for instance) reduces RLR (Council et al. 2005). Moreover Carnis and Kemel (2012) show that violation rates are higher during night and low-traffic time periods when crash risk is lower.

The impact of red light duration on RLR was highlighted by Retting et al. (2008). When waiting time is too long, drivers fail to respect it. Guidelines recommend not having red light durations that exceed 2 min (CERTU 2010).

Carnis et al. (2012) report field data showing that most RLRs occur during the very first seconds of the red phase, when the violation is the most profitable in terms of avoided waiting time.

Heterogeneity is also expected between users, because of the diversity of individual preferences. Retting et al. (1999) compare authors of RLR accidents to those of other accident types. Males are overrepresented among this population. Red light violators are also younger and more likely to be intoxicated. Porter and England (2000) observed a relationship between RLR and safety-belt use. Propensity to abide to red light also depends on the vehicle type (Carnis and Kemel 2012).

Coping with Dilemma and Interactions Between Drivers

The decision to respect the rule must be taken in a very short amount of time. Indeed, drivers must make the go/stop decision within a few seconds. Because of the urgency dimensions of the decision and drivers' cognitive limits, illegal actions can sometimes be taken by mistake (Depken and Sonora 2009). Decision to go or stop at light also requires the driver to analyze the situation because the presence of closely following vehicles must be checked. If the decision to stop is likely to trigger a rear-end collision, decision to run the light must be taken. Consequently, illegal decision can be followed in particular situation for avoiding harm and costly consequences. Those aspects are not generally accounted for by the economics of crime framework that assumes that decision makers have time to choose, face clear-cut situations, and feature perfect cognitive capabilities.

The dilemma that faces the driver approaching light received an important attention in the literature (Elmitiny et al. 2010; Papaioannou 2007). The situation in which the driver is unable to stop safely or crossing the intersection at the green light is called the dilemma zone. The dilemma zone is related to the duration of amber light and the approaching drivers' speed. Shortening this time increases RLR because drivers are not averted that the light will switch. Increasing this time increases the dilemma zone and may increase the number of drivers running amber

light. Drivers exceeding speed limits are more likely to run amber and red light. Therefore, the dilemma zone does not only puzzle drivers but network managers as well.

Decision to run or not the red light is not only individual, but it is also impacted by other drivers' behavior. The choice to commit a RLR takes into consideration the presence of other (preceding or following) drivers. For instance, drivers are more likely to run a light when a preceding driver did so (Elmitiny et al. 2010, p. 110). Observing that the preceding user runs the light may provide valuable information for decision that enforcement is low or nonexistent. Even though following behavior can be rational, it also creates risk of rear-end crash if the preceding driver decides to stop at the traffic light.

Consequences of Traffic Light Violations

Safety Consequences

Red light violation is a major concern for the policy makers because of the number of road crashes and victims involved (McGee and Eccles 2003). From the economist standpoint, road crashes are interpreted as an external effect related to the common use of the road network.

Moreover, the urban intersection implies mainly the involvement of vulnerable users (pedestrians, bicyclers, and motorcyclists). It means also the collision is characterized by a true asymmetrical dimension in terms of vulnerability between the involved users in a traffic collision (for instance, vehicle vs. pedestrian).

Large-scale studies evaluating the prevalence of RLR are not common. Retting et al. (1999) report that accidents occurring at intersections represent 27% of all injury crashes in the United States. Accidents due to RLR are however less frequent. Over the 1992–1996 period, RLR crashes represented 3% of all fatal crashes and 7% of injury crashes on urban roads. Compared to the prevalence of violations, these figures suggest that the collision probability in case of RLR is much lower than one could expect. According to the economic approach, violators may also decide to run red light when the traffic conditions and the

visibility minimize crash risk. Carnis et al. (2012) observed that 90% of violations occur in the first two seconds of the red phase, when all lights of the intersection are red.

Paradoxically, a sizable part of intersection crashes derive from red or amber light stopping. Rear-end accidents are indeed not infrequent at signalized intersection. Their number has been found to increase after traffic light camera deployment (Erke 2009). Another frequent type of accident occurring at signalized intersection relates to left turns. Wang and Abdel-Aty (2006) estimate that these accidents rank third after rear-end and angle crashes for 1531 intersections in the state of Florida.

Traffic Regulation Consequences

Traffic regulation is another major objective for installing traffic lights. Therefore, consequences in terms of generated congestion and the related time losses have to be assessed. Time losses can be generated by two types of traffic light violations. First, when the traffic light regulates road access, failure to respect the red light disturbs traffic flow and increases congestion. In this case, the contribution of the marginal violator to congestion is small, but the overall effect can be important when violations are numerous. Second, when RLR occurs during a dense traffic condition, the RL runner can be stuck in the middle of the intersection and can totally freeze traffic on all junctions.

A better respect of red light can help in limiting congestion and save environmental costs related to air pollution. We are not aware of any study evaluating the impact of RLR on time losses, nor environmental costs, due to increased congestion, even if they have to be taken into consideration from an economic perspective.

Regulation of Red Light Violations

Red light violation is a source of external effects. It generates a social cost (mainly associated with the crash costs (material damages and injuries)), which requires internalization. Internalization of this external effect calls for an intervention aiming at the reduction of costs borne by the victims. To mitigate the consequences related to those illegal

behaviors, the policy maker defines and implements a public policy. This social regulation intervention can be achieved by two different categories of policies: enforcement and other interventions.

The Enforcement Policy

Enforcing the Highway Code

Becker's seminal works on the economics of crime show that illegal behavior can be mitigated by implementing an efficient policy of control and punishment (Becker 1968). Both the enforcer and the enforcement authority are concerned by the economic approach to crime. Efficiency of this enforcement policy requires taking into consideration the cost of intervention (respectively the relative costs of detection and punishment) and the social loss related to the harmful consequences of red light violations which could be reduced by deterrence. At the society level, it then becomes possible to determine an optimal deterrent policy associated with an optimal punishment (in terms of intensity of detection and severity of sanction) and an optimal number of violations. Consequently, it is rational from the economic perspective not to enforce all RLRs.

Different Techniques of Production

Different ways exist to enforce traffic light regulation. The traditional approach rests upon the manual detection of offenders by police officers, who monitor and intercept the offenders. This procedure is very costly in terms of time, because it requires a permanent supervision and numerous police officers to be able to catch the offender. In economic terms it is a labor-intensive technique of production. In practice, red light regulation was not especially enforced, because of its high unitary enforcement costs.

Since the mid-1980s, red light cameras (RLCs) have been replacing progressively the traditional enforcement method. This technique of detection can be considered as capital intensive and makes possible a systematic supervision of all the drivers, while minimizing the costs of labor intervention. Automation of traffic safety enforcement is a major trend of those last years, which has to be considered for understanding the spreading of such public programs.

When compared with the traditional approach, the RLC program appears as an efficient way for enforcing the regulation. It presents twofold economic advantages. It reduces substantially the cost of detection and punishment at a given level of traffic. The picture of the offender is automatically processed. The offender is identified through his license plate and receives his traffic infringement notice at home. It permits also to increase substantially the level of detection and punishment. Thousands or millions of tickets can be processed according to the limits of the computer system. In France, the number of RLR tickets was multiplied by 8 after the introduction of RLC. Introduction of RLC programs can be conceived as an innovation lowering the average cost of deterrence and making possible a stricter enforcement of red light regulation by generating scale economies. This cost killing effect explains probably why so many jurisdictions implemented such programs for securing the signalized road intersection (Carnis 2010).

Do RLCs Reduce Crashes?

While several contributions conclude to a positive contribution of RLC by reducing road injuries (Council et al. 2005; McGee and Eccles 2003), others show more debatable effects and question their impact. RLC would yield positive side effects with potential spillover impacts of RLC for other intersections and negative ones by increasing rear-end crashes and all category crashes (Hallmark et al. 2010; Vanlaar et al. 2014). However the gains associated with the reduction of right-angle injury crashes would largely compensate the costs related to the increase of rear-end crashes. More problematic are the recent conclusions of several contributions showing the insignificant impact of RLCs for reducing road crashes (Erke 2009; Høye 2013), contributions which were nevertheless criticized by other scholars putting in question their meta-analysis approach (Lund et al. 2009).

Cost-Benefit Evaluation is Needed

An economic approach to red light violation and regulation becomes particularly necessary when such a public intervention yields opposite and

potential adverse side effects. It constitutes a prerequisite for concluding about the economic efficiency of such programs for reducing road injuries at signalized intersection. Proceeding to the economic assessment of RLC programs requires a comparison between advantages and costs. However, only few studies investigated the economic side of red light violations. More problematic is the finding of a careful literature review showing the quasi-generalized absence of economic assessment of RLC programs and rigorous evaluation of safety impacts, so that it is impossible to conclude that such programs are efficient and to determine the scope of the internalization policy (Langland-Orban et al. 2014). In fact, the present evaluative practices of RLC programs reflect both the complexity of evaluation process (non-replication of experiences in controlled laboratory conditions) and the costs of collecting and analyzing the data. It seems also to reflect that policy makers sometimes look for intervention whatever may be their impact or cost, when facing the risk of human injuries.

Public-Private Partnership for RLR Enforcement

The economic approach is particularly relevant when programs are not directly managed by governments. There are several procurement alternatives. Some of them could associate private operator, while some governments outsource the operation of the program (FHA 2005). The total or partial outsourcing of such social regulation activity raised some new issues concerning the possibility for contractor to manipulate the control activity and illegal use of the collected data (CSA 2002). Such situation is typically a principal-agent situation with asymmetrical information. Indeed, one agent is usually more informed than the other and can modulate its efforts. This contractual dimension emphasizes the necessity of a well-designed contract to be insured that private and public interests are aligned (Travis and Baxandall 2011). Indeed, while governments are more interested in maximizing their return in terms of safety impact (public safety hypothesis), the private firms are more concerned by the maximization of profit. Those considerations are quite important, because

it could influence the location of radars and their impact for public safety.

Another interesting issue is related to the different payment options for the contractor. Fixed-price payments, fixed monthly payments, per citations payments, payments depending on time worked and materials used, and mixed payments are alternative possibilities. However, it is not clearly determined which type of payment is the most advantageous for the government and the most efficient in terms of welfare for the society. Nevertheless there are strong incentive implications for the different agents, especially here for the policy maker and the contractor. Unfortunately this dimension was not investigated.

RLC programs have to be considered also from the institutional perspective (Carnis 2010). Outsourced programs, contractual dimensions, and financial considerations are important characteristics. A more recent trend fires on the RLC programs. More and more governments turned off their RLC because of uncertain impacts in terms of traffic safety already mentioned. Between 2011 and 2013, it is estimated that 200 RLC programs were turned off in the United States (Slone 2014). The policy maker is reluctant to let a program continue while it could increase rear-end injury accidents and potentially jeopardize human lives. Moreover the court system becomes less supportive of such control system: the judge dismisses charges more often because of erroneous readings and identification of some license plates by the program, which questions its reliability. Another consideration concerns the reduction of revenues associated with the RLC while the costs are increasing. Moreover some citizens assimilate RCL fines as a new tax imposed upon the road user. Garrett and Wagner (2009) concluded that sustained municipalities obey revenue motives concerning traffic enforcement and tickets. RLC would not be exclusively concerned with public safety.

Other Policies

Providing Drivers With Better Information

The drivers' decision of stopping or running the red light depends on beliefs and preferences.

However most of the time the driver is not perfectly informed about the risks involved. Consequently, education and awareness campaign can play a useful role in providing accurate information related with the risk the driver faces when taking an adverse decision (FHA 2005). While education and awareness campaigns are conceived here as a provision for helping him in taking a correct decision, it presents a cost. Such campaigns have to be calibrated so that the costs and returns are in a same magnitude.

Nudging Drivers

Behavior change can also be achieved through nudging. This policy consists of framing the decision context. More precisely, the policy maker can design an environment that induces a promoted behavior. Thaler and Sunstein (2008) provide an illustrative example of such policy in the road safety field. The use of stripes can reinforce the visibility of a potential danger of a portion of a curve for instance (Thaler and Sunstein 2008, pp. 37–39). A review of possible applications of nudges to traffic safety policies is proposed by Avineri (2014). Regarding RLR, installing countdown systems can impact drivers' behavior and appears as a typical nudging intervention.

No Traffic Light, No Traffic Light Violation

Red light violation depends also on some Highway Code adaptations and road infrastructure context. For instance, in the United States, users are generally allowed to a right turn during red light as long as they leave priority to other vehicles. During low-traffic hours (e.g., night hours), traffic light can be turned out and the right of way applies, avoiding the unnecessary waiting time at the green light phase. In France, an experiment tests the impact of giving to the bicycle user the possibility to cross the intersection at a red light provided that the priority is given to the opposite coming vehicle.

Reframing the context of the driver decision can also require bringing some modifications to the road infrastructure. Engineer investigations showed the influence of the average daily traffic

volume, the number of traffic lanes, the left-turn lanes, and the speed limit regulation (Langland-Orban et al. 2014). A radical solution for regulating red light violation would consist of removing signalized intersection. In that case, RLR would disappear because the road infrastructure design makes them impossible. In some ways, it could constitute a kind of situational crime prevention approach. Concretely, it would consist of modifying the access to the road section through ramps or implementing roundabouts.

However such interventions can be very costly, especially in an urban context. Again a reasonable economic approach would consist of comparing costs and gains of different alternatives. This approach permits also to avoid the funnel approach by enlarging the problematic to other issues such as mobility and pollution considerations, emphasizing that red light violation prevention cannot be reduced only to public safety consideration.

Conclusion

The economic approach provides a consistent framework for understanding RLR. It is able to account for both users and policy makers decisions and highlight possible alternatives for intervention. It can also explain why it can be rational for a driver to commit a RLR under certain circumstances, but also why red light regulation is not enforced in some cases.

Economic variables are not only at play for explaining the way drivers choose in particular situations, but the economic consequences related to road crash and traffic congestion have also to be considered for understanding the role of traffic light. Economic valuation appears as a true alternative to the engineering perspective for understanding this issue and promotes different analysis and solutions.

Regulation of RLR is achievable and requires a calibrated enforcement policy. RLC program is a possible solution for enforcing traffic safety rules, but an economic approach is needed for designing

correctly the public intervention, which could be assimilated to a particular productive process. Communication campaign, awareness program, and infrastructure modification are other available solutions. Nudging policy appears also as an interesting perspective that can be built upon a behavioral law and economic approach, providing new insights for designing traffic safety rules and enforcement policies.

Transaction Costs

Wim Marneffe, Samantha Bielen and
Lode Vereeck

Faculty of Applied Economics, Hasselt
University, Diepenbeek, Belgium

Abstract

Transaction costs is a generic term referring to the costs of transacting through the market (e.g., search, information, contract, monitoring costs). They are applied with different meanings to organizational structures (e.g., vertical integration), market failures (e.g., externalities), institutional choices (e.g., promotion of clubs), and public choice (e.g., administrative burden).

Introduction

If markets operate as smoothly and efficiently as free market proponents and standard economic textbooks suggest, why, for instance, do firms hire workers on a permanent basis or are professions regulated? The answer is, to a large extent, transaction costs. In principle, every single activity (e.g., typing a letter, making a phone call) can be outsourced to the market. However, searching, finding, screening, contracting, and monitoring a secretary is extremely costly. These “transaction” costs of using the (labor) market can outweigh the proclaimed benefits of allocating productive activities (i.e., a letter, a phone call) through the market. Therefore, legal instruments are created (e.g., labor contract of unlimited duration) in order to avoid transaction costs.

Similarly, the regulation of professions (e.g., licensing of dentists) not only guarantees a standard quality, but also creates barriers of market entry. However, the oligopolistic costs that stem from these barriers are typically offset by the search, information, screening, contracting, and monitoring costs of using the free market of professional services, i.e., the transaction costs.

Transactions costs should always be considered in their historical context. The use, for instance, of labor contracts of unlimited duration is a way to reduce transaction costs outweighing monopolistic costs (i.e., barring other secretaries to type a letter or make a call). However, the emergence of temporary workers' agencies that offer flexible services is a market response to high transaction costs. What is an economic reason to avoid the use of the markets today may not be valid tomorrow.

The concept of transaction costs is probably among the most discussed topics in economics and has led to the emergence of an entire body of literature with numerous theoretical and empirical articles and books. Economists' understanding of transaction costs has continuously evolved since it was first introduced by Ronald Coase trying to explain the emergence of firms (Coase 1937). Currently, transaction costs are an essential part of economic analysis and frequently invoked to explain a plethora of institutional choices and behavior (Rao 2003). Unfortunately, the transaction cost literature is plagued by the use of different definitions. Therefore, this essay presents a consistent and coherent taxonomy of transaction costs.

Transaction Costs: The Prelude

Although Ronald Coase did not explicitly use the words "transaction costs" in his 1937 article on "The Nature of the Firm," he was the first to introduce the concept in order to explain the existence of firms instead of organizing economic activity through exchange of transactions across the market (Coase 1937). According to Coase, "we had a factor of production, management, whose function was to coordinate. Why was it needed if the pricing system provided all the coordination necessary?" (Coase 1993). Before Coase, creating a firm or using the market were viewed as alternative modes for coordinating production. At the time, the mainstream microeconomic assumption was that the use of the firm or the market for production was a given, not a choice (Williamson 2010).

Coase was the first to observe that firms arise because there are substantial costs involved in using the price mechanism of the market. At first, he was not very explicit about the meaning of these transaction costs. He did not provide a clear definition, but described transaction costs as the cost of "discovering what the relevant prices are" or "negotiating and contracting costs" (Coase 1937). Back in 1937, Coase did not fully grasp his own accomplishment and was merely trying to reveal the weaknesses of the dominant Pigouvian analysis of the divergence between private and social products (Coase 1993). In the late 1950s, research on market failures started, notably after the article of Samuelson on "The Pure Theory of Public Expenditures" (Samuelson 1954). At the time, few authors (e.g., Coase, Buchanan, Calabresi) considered externalities not as a market failure, but pointed out that under certain conditions "harmful effects" are not problematic for the efficiency of market mechanisms (Marciano 2011).

Transaction Costs: The Sequel

In 1960, Coase published another article on the "Problem of Social Cost" which is unmistakably one of the most cited articles in the economic and legal literature and helped launch the economic analysis of the law (Medena 2011).

In analyzing externalities (or "social cost issues" as they were called back then), Coase used the famous example of a rancher whose cattle destroys crops on the land of a neighboring farmer. First, it is assumed that the cattle rancher is fully liable for harm caused "and the pricing system works smoothly," i.e., a zero transaction cost model. Under liability, the efficient level of both cattle and crops will be produced, either through damage payments from the rancher to the farmer or through compensatory payments from the rancher to the farmer to take land out of cultivation (if that is the least-cost solution). This way, external costs are fully internalized under the liability rule. The actual level of damage payments is determined by "the shrewdness of the farmer and the cattle-raiser as bargainers" (Coase 1960).

Second, Coase discusses a situation in which the rancher cannot be held liable for the damage caused by his cattle. In this case, the resulting level of production of both cattle and crops is also efficient, since it is in the farmer's own interest to pay the rancher to cut the size of his herd up till the point where the payment is less than the benefit from reduced crop damage. Similarly, the rancher is willing to cut the size of his herd if the farmer's payment at least equals the foregone benefit resulting from the herd reduction. Again, external costs are fully internalized and both cattle and crop outputs are equal at the levels under liability.

Coase concludes that the initial assignment of legal property rights has no impact on the efficient use of resources. As discussed in the previous paragraph, both situations liability and non-liability lead to an efficient level of production of both cattle and crops. However, this conclusion only holds when the pricing system works at zero transaction costs. This insight has become known as "the Coase theorem." Interestingly, it was Stigler who coined this term in 1966 (Stigler 1966). In case of multiple farmers, substantial transaction costs may arise. Under liability, each individual farmer sues the rancher, hence transaction costs are low and the efficient level of production is attained. In case of non-liability, however, each individual farmer faces three inefficient options: (1) do nothing and bear the costs of crop damage, (2) build a fence around the individual property which on aggregate may outweigh the costs of herd reduction, or (3) try to negotiate a herd reduction which may cause substantial transaction costs, such as gathering information, contacting and discussing with other farmers, and negotiating with the rancher. Putting aside the potential free-rider problem, the latter "transaction" costs, however, can be so substantial that the farmers resort to option one or two.

Later on, Coase (1960) clarified that "to carry out a market transaction, it is necessary to discover who it is that one wishes to deal with, to inform people that one wishes to deal and on what terms, to conduct negotiations leading up to a bargain, to draw up the contract, to undertake the inspection needed to make sure that the terms of the contract are being observed and so on." The

costs that accompany these activities may hamper transactions that would have taken place if using the pricing system did not evoke such costs (Coase 1960). Furthermore, he suggests that the existence of externalities can partly be explained by the presence of transaction costs that are sufficiently large to prevent market-functioning mechanisms to internalize external costs. At the time, Coase criticized the neoclassical Pigouvian model for ignoring the existence of transaction costs. In 1993, Coase pointed out that his article had demonstrated "the emptiness of the Pigouvian analytical system" and helped to frame the discussion on externalities in a more realistic way (Coase 1993). The Coase theorem was initially met with a lot of skepticism by other scholars who condemned the underlying assumption of efficient markets as unrealistic and even "Utopian" (Blum and Kalven 1967).

Transaction Costs: Definitions

The publication of "The Problem of Social Cost" in 1960 did not lead to the immediate absorption of the idea of transaction cost reasoning in economic literature. In 1969 Kenneth Arrow defined transaction costs as "the costs of running the economic system" (Arrow 1969). But, it was not until 1985 that transaction cost reasoning became more widely known due to Oliver Williamson, who defined it as "the economic equivalent of friction in physical systems" (Williamson 1985). In an effort to put the concept of transaction costs into practice, Williamson explains: "Transaction cost economics is an effort to better understand complex economic organization by selectively joining law, economics, and organization theory. As against neoclassical economics, which is predominantly concerned with price and output, relies extensively on marginal analysis, and describes the firm as a production function (which is a technological construction), transaction cost economics (TCE) is concerned with the allocation of economic activity across alternative modes of organization (markets, firms, bureaus, etc.), employs discrete structural analysis, and describes the firm as a governance structure

(which is an organizational construction). Real differences notwithstanding, orthodoxy and TCE are in many ways complements – one being more well-suited to aggregation in the context of simple market exchange, the other being more well-suited to the microanalytics of complex contracting and nonmarket organization” (Williamson 2008).

In turn, Barzel (1997) described transaction costs as “the transfer, capture, and protection of exclusive property rights.” This is a rather narrow definition of transaction costs, yet often used by scholars from the property rights movement.

More recently, the scope of transaction costs was broadened, leading Challen (2000) to state that transaction costs include all costs associated with any allocation decision, including the costs of uncertainty. Stavins (1995) claimed that transaction costs are “ubiquitous” in market economies, since parties must find one another to transfer, communicate, and exchange information. Douglass North (1990) went even further and considered transaction costs as a part of production costs.

Nowadays, transaction costs are an essential part of mainstream economics and are being applied with different meanings to organizational structures (e.g., vertical integration), market failures (e.g., externalities), institutional choices (e.g., promotion of clubs), and public choice (e.g., administrative burden). Transaction cost is now a generic term referring to costs occurring when making a transaction in the market. Accordingly, transaction costs can be interpreted as “the costs of any activity undertaken to use the price system” (Demsetz 1997).

Towards a Classification of Transaction Costs

The discussion above concerning the definition of transaction costs clearly shows the need for a coherent and complete classification of transaction costs. Dahlman (1979) was one of the first scholars to propose a categorization of transaction costs. In accordance with Crocker (1971), he distinguished three types of costs: (1) search and

information costs, (2) bargaining and decision-making costs, and (3) monitoring and enforcement costs. However, Milgrom and Roberts (1992) used another classification of transaction costs: on the one hand, costs stemming from information asymmetries and incompleteness of contracts among parties and, on the other hand, costs following imperfect commitments or opportunistic behavior of parties. Furthermore, Foster and Hahn (1993) brought some new elements into the discussion and emphasized the distinction between direct financial costs (of engaging in trade), costs of regulatory delay, and indirect costs (associated with the uncertainty of completing a trade). A more basic classification is made by Dudek and Wiener (1996) who included search, negotiation, approval, monitoring, enforcement, and insurance costs.

One of the most interesting classifications of transaction costs is the one by Furubotn and Richter (1997). They describe transaction costs as the costs of establishing, maintaining, adapting, regulating, monitoring, and enforcing rules as well as executing transactions. Their definition of transaction costs is “the costs of resources utilized for the creation, maintenance, use, change, and so on of institutions and organizations. [...] When considered in relation to existing property rights and contract rights, transaction costs consist of the costs of defining and measuring resources or claims, plus the costs of utilizing and enforcing the rights specified. Applied to the transfer of existing property rights and the establishment or transfer of contract rights between individuals (or legal entities), transaction costs include the costs of information, negotiation, and enforcement.” The authors identify three sorts of transaction costs: the costs of using the market (market transaction costs), the costs of exercising the right to give orders within the organization (managerial transaction costs), and the costs of running and adjusting a political system (political transaction costs). Each of these three categories comprises both fixed transaction costs (setup costs for institutional arrangements) and variable transaction costs (dependent on the number of transactions). Furthermore, it should be noted that the authors make a useful distinction between *ex ante* (e.g.,

search and information costs) and ex post (e.g., monitoring and enforcement costs) transaction costs. Thus, the Furubotn and Richter classification integrates the costs of using the market as mentioned by Coase, the managerial costs identified by Williamson, and the institutional costs put forward by North.

Unfortunately, the Furubotn-Richter taxonomy has one serious drawback. In their effort to provide a comprehensive classification, they associate “transaction costs” with the use of markets as well as regulations, which undermines the very meaning of the concept. Furubotn and Richter (1997) rightly claim that regulation entails costs. However, these costs are precisely the opposite from the (Coasean) transaction costs, which refer to the use of the market and thus terminologically unsound. Moreover, the policy goal of regulations is precisely to reduce transaction costs. Adding to the confusion, the OECD in 2001 also made the distinction between non-policy-related transaction costs (in which parties incur costs of voluntary market transactions) and policy-related transaction costs (resulting from the implementation of public policy).

It is clear that the distinction between transaction costs and regulatory costs should be strictly observed. Therefore, Marneffe and Vereeck (2011) suggest that the term “regulatory costs” is exclusively used to refer to the costs of interfering in, correcting, or barring the use of markets. They recommend to short-term the policy-related costs of regulation as “regulatory costs” and non-policy-related costs of using markets as “transaction costs.”

Transferable Discharge Permits

Cornelia Ohl

HA Hessen Agentur GmbH, Transferstelle für Emissionshandel und Klimaschutz, Wiesbaden, Germany

Abstract

There are different approaches for dealing with water, air, and soil pollution, for example, the prescription of an emission or immission standard by environmental law or pollution reduction by economic instruments like *transferable discharge permits* (TDP). The idea of TDP is to control the pollution level in the environmental media by economic incentive setting (see, e.g., Tietenberg T, Lewis L (2014) *Environmental & natural resource economics*, global edition, 10th edn. Pearson Higher Education; for an introduction in economic theory). This requires the setting of a critical threshold level for pollution control – e.g., a safe minimum standard – and the breakup of this standard (“cap”) in permits that can be traded on a market.

The most prominent application of TDP in Europe is the trading of CO₂ emissions in selected sectors of the economy (EU-ETS; see, e.g., Ellerman D, Convery F, de Perthuis C (2010) *Pricing carbon: the European Union emissions trading scheme*. Cambridge University Press, Cambridge, UK/New York (also published in French: *Le Prix du Carbone: Les enseignements du marché du carbone*, London: Pearson, 2010); Endres and Ohl (Eur J Law Econ 19:17–39, 2005)). It can be seen as a flagship approach for a European-Union-wide harmonization of environmental laws and regulations for emission control by economic incentive setting.

What Is It About? Proposal for an Alternative Heading: The Idea of Transferable Discharge Permits

There are different approaches for dealing with water, air, and soil pollution, for example, the prescription of an emission or immission standard by environmental law or pollution reduction by economic instruments like *transferable discharge permits* (TDP). The idea of TDP is to control the pollution level in the environmental media by economic incentive setting (see, e.g., Tietenberg and Lewis 2014 for an introduction in economic theory). This requires the setting of a critical threshold level for pollution control – e.g., a safe minimum standard – and the breakup of this standard (“cap”) in permits that can be traded on a market.

The most prominent application of TDP in Europe is the trading of CO₂ emissions in selected sectors of the economy (EU-ETS; see, e.g., Ellerman et al. 2010; Endres and Ohl 2005). It can be seen as a flagship approach for a European-Union-wide harmonization of environmental laws and regulations for emission control by economic incentive setting.

Market Design by Environmental Legislation

The standard can be fixed on different backgrounds, on social welfare considerations, aspects of human health, and nature protection, among others. In reality, we often find a mixture of different factors including political, economic, and natural science considerations. In any case, the standard is to split into permits which with regard to the regulated subject and area allow a certain amount of pollution and are valid for a certain time period. This poses questions of monitoring and measurement.

Pollution is usually a by-product of valued goods and services which make the measurement tricky, especially in cases where direct measurement is impossible and indirect calculations or assessments are required. To ensure that the assigned amount can be traded, the certified metric needs to mean the same for any regulated body irrespective of the type of good or service it provides. For this reason, clear regulations on monitoring and measurement are necessary. It is also to ensure that the number of permits certifies the critical threshold value set by the regulating authority.

In a further step, the regulating body is to issue the permits either free of charge or by selling them for a fixed price or through bidding or auctioning mechanism. Moreover, to guarantee that the polluters perform with the standard, reporting on the polluting activities is essential. It calls for the establishment of an accounting system that can be verified by independent experts. This supports proving performance with monitoring and measurement rules and individual compliance, i.e., if the polluters keep their polluting activity within the limit allowed by the number of permits they hold. If the polluting behavior is inconsistent with the assigned amounts, an enforcement mechanism is needed that makes the polluter stick to its obligations, for example, a penalty fee in combination with a belated reduction of excessively released pollutant.

Incentives for Permit Trading

Keeping within the limits of a standard frequently requires measures for emission/immission reductions. These measures raise different costs for the regulated bodies. To keep them at minimum, economists argue for the establishment of a market where the permits can be traded.

Although the market does not guarantee that the polluters with the lowest cost actually reduce the pollutant – the polluter is generally free to decide whether to buy permits or change the polluting behavior – it nevertheless encourages minimizing the cost of pollution control. If polluters maximize profits, they will take advantage of the cheapest way of pollution reduction. The polluter thus has incentive to compare the market price of a permit

with the individual reduction costs. As long as the cost for buying permits is lower than the cost of measures for pollution control, the polluter shows a demand for permits. On the other hand, polluters with low control costs are willing to reduce their pollution level in order to sell permits on the market, at least as long as the price they receive for the permit is higher than the individual reduction costs. This mechanism ensures that the standard is enforced at minimal costs.

Despite this advantage, the market approach is often criticized. One argument is that polluters with high reduction costs lose incentives for pollution control and let others do the job. The question, however, is whether society is concerned of the pollutant to stay within the prescribed limit or whether the concern is on who is responsible for taking measures. If the goal is pollution control, the market-based approach has clear advantages in terms of both social welfare and environmental protection: it first of all draws the focus on pollution reduction to the desired extent and second to incentive setting for cost minimization. The question of responsibility, nevertheless, can be addressed by selecting the group of polluters having to perform with the environmental regulation.

Applications and refinements of TDP as well as further criticism are found in the literature (e.g., see Hansjürgens et al. 2011; OECD 2004).

Transition Economies: Rule of Law and Credible Commitment

Rosolino A. Candela¹ and Ennio Piano²

¹Political Theory Project, Department of Political Science, Brown University, Providence, RI, USA

²Department of Economics, George Mason University, Fairfax, VA, USA

Abstract

Must the rule of law spring upon us solely by accident and force, or can it also emerge as a product of political reflection and choice? As

the lessons from the political and economic transition of centrally planned economies in Europe and Asia illustrate, the transitional movement requires an element of political reflection and deliberate choice, specifically the establishment a binding and credible commitment to limits on state action. In order to do so, credible commitment to the rule of law must be signaled *ex ante* by political reformers if reform efforts are to be successful, from which economic development follows *ex post*. The historical record shows, however, that efforts to establish the rule of law in transition economies have been mixed. This chapter explains why this is the case, specifically by comparing Russia and China as case studies of transitional political economy.

Introduction

Must the rule of law spring upon us solely by accident and force, or can it also emerge as a product of political reflection and choice? In a previous chapter of this encyclopedia, we discussed the role in which interjurisdictional competition between states and intrajurisdictional competition between interest groups constrained governments to obey its political commitments to enforce property rights, in which the rule of law emerged as a by-product of this process. However, as the lessons in the political and economic transition of centrally planned economies show, the transitional movement requires an element of political reflection and deliberate choice (see Hayek 1973: 45; Wagner and Runst 2011), specifically the establishment of a binding and credible commitment to limits on state action (Boettke 2009). In order to do so, credible commitment to the rule of law must be signaled *ex ante* by political reformers if reform efforts are to be successful, from which economic development follows *ex post*. The historical record shows, however, that efforts to establish the rule of law in transition economies have been mixed. This chapter explains why this is the case, specifically by comparing Russia and China as case studies of transitional political economy.

The Problem of Credible Commitment

There lies a fundamental dilemma in every attempt to establish the rule of law in those economies undergoing a transition away from national economic planning: how do we resolve the paradox of governance? In order to create the conditions conducive to exchange and capital accumulation, governments must be strong to enforce property rights and contractual arrangements. Doing so enables individuals to devote less effort and resources preventing “first-level predation,” meaning predation by private actors, and specialize in productive entrepreneurial activities. Eliminating first-level predation, however, introduces the problem of “second-level predation,” or predation by public actors (Boettke 2009: 47; see Acemoglu and Johnson 2005). Governments that are strong enough to enforce private property rights and prevent private predation are also strong enough to break any constraints to such precommitments in the future. Public predation can manifest itself in several ways, including the outright confiscation of wealth, taxation, and inflationary finance through currency debasement (Montinola et al. 1995: 54). The cost of such predation in terms of economic development is “evasive entrepreneurship,” which includes the expenditure of resources evading the legal system (Coyne and Leeson 2004: 57), via tax evasion, bribery, or withholding efforts to invest in physical and human capital. If government is given enough power to enforce the rules necessary to maintain an economy, then it must also credibly commit to honor such rules.

Why is it difficult for government officials to credibly commit to the rule of law? This can be explained by the absence of a “political Coase theorem” (Acemoglu 2003). The Coase theorem states that when private property rights are well defined and transactions are low, individuals will bargain to an efficient outcome, irrespective of the initial assignment of property rights (Coase 1960; Stigler 1966: 113). Implicitly, the Coase theorem assumes that parties to an exchange are full residual claimants and will therefore bear the full costs and benefits of the outcomes of their decision-making. Therefore, if one party to an exchange

breaks an agreement, or if both parties are disputing an agreement, reputational mechanisms or the state is available to enforce contractual agreements. Failure to abide by an agreement will result in a loss of reputation in future trading periods and/or state punishment. The Coase theorem applied to the context of political decision-making, however, is quite different. The logic of political decision-making is to concentrate benefits on well-informed and well-organized interest groups that represent a politician’s constituency and disperse costs on the masses of the ill-informed population (Boettke 1993: 7). Such a logic prevails because the governmental official who promises institutional reform to their citizenry will not bear the full costs of renegeing on such a promise. Whereas in the previous example, a private actor faces costs in terms of state punishment and loss of reputation, government officials only bear a loss in reputation. However, even these costs are not fully concentrated on the particular public actor, but are spilled over onto future generations of public actors, who face an increasingly distrustful citizenry, making it more difficult in future “trading periods” to implement transitional reforms.

In order to overcome the expectations that the citizenry hold with regard to credibly committing to the rule of law, governments must signal their willingness to tie their hands *ex ante* against using discretion to unforeseen economic circumstances *ex post*. Signaling refers to the transmission of information that is costly for a sender to emit, but is “cheap” for another party to receive, in this case government officials being the senders and the citizenry being the recipients. Without a credible commitment to the rule of law via signaling, “it is of course perfectly rational for private agents to discount announcements of future policy reforms – or assurances of the continuation of present reforms” (Rodrik 1989: 757). Rodrik argues that any successful institutional reform will have a bias towards “overshooting” in its signaling strategy. This implies that there will be inverse relationship between policy overshooting and credibility: the more severe the credibility gap, the greater the policy must overshoot in order to send the appropriate signal and overcome

the problem of credible commitment. For example, a central banker who wishes to credibly commit to sound monetary policy could adopt a rule that pegs the exchange rate, allowing citizens to convert the domestic currency into foreign currency at a preannounced rate. However, a central bank with a long record of inflationary policy will be sending a noisy signal, especially if devaluation is expected in the face of speculative attacks. In order to overcome the gap of credibly committing to currency debasement, policymakers may have to overshoot even further by adopting a more binding constraint that eliminates its discretion completely. Examples include dollarization or the private-issuance of competitive currencies (Selgin and White 2005; see also White 2010). Therefore, establishing a credible commitment to the rule of law not only requires sending a strong signal to execute institutional reform, but also establishing a binding constraint that eliminates political discretion. Once this takes place, economic and political transition can move into a wealth-creating path.

The Rule of Law and Transitional Political Economy

Fundamentally, transitional political economy entails an institutional change in the manner in which property rights are structured and governed, both in terms of formal government enforcement and informal institutional arrangements, such as customs, traditions, and norms. Broadly speaking, property rights refer to social relationships that guide expectations about the use of scarce resources (Furubotn and Pejovich 1972). Political and economic transitions are intertwined by changes in the de facto structure of property rights. The transition to a private property rights-based economy, based on freedom of exchange and freedom of contract, leads to a reallocation of wealth previously based on political connection and patronage. Respect for private property under the rule of law promotes political freedom because it separates economic power from political power and in this way enables the one to offset the other. It enables economic strength to be a check to

political power rather than its reinforcement (Friedman 1962 [2002]: 15). Such an institutional transition will imply transaction costs that are not only economic and political, but cultural and historical as well.

Implementation of the rule of law in transitional economies implies the elimination of existing political privileges, specifically de facto control over the use of resources. Therefore, economic and political transition will generate a massive redistribution in income. This in turn will imply the opposition of a large class of government officials and military personnel whose rank and privileges will be threatened by transition to market economy under the rule of law. Theoretically, this problem could be eliminated by paying those individuals the present discounted value of the income derived from holding political power, particularly through de facto control over state-owned firms and its resources. However, when the transitional costs associated with compensating the current benefactors of the existing system are greater than the associated welfare gains dispersed among the population, this will create what Gordon Tullock refers to as a “transitional gains trap” (Tullock 1975) that impedes the implementation of the rule of law.

The process of institutional transition from a socialist economy to a market economy is not only economic and political in nature, but also cultural (Pejovich 2003). Culture refers to the context where goals of individuals and the means to be employed by individuals are shaped and given meaning (Storr 2013: 54). The way in which property rights are perceived and “what constitutes an appropriate disposition of property, are all (partly) determined by culture” (Storr 2013: 32). Therefore, culture will affect the ability for governments to credibly commit to uphold the rule of law. Steve Pejovich has argued that “*the cultural differences between Central and East European countries are a major determinant of the magnitude of their respective transaction costs*” (emphasis original, Pejovich 2003: 352). Countries that have a “command culture,” which perceives the exchange of property rights to be a zero-sum game, will face higher costs of credibly committing to the rule of law than a “culture of

exchange” that regards the exchange of property rights to be mutually beneficial (see Buchanan 1997: 95–101). This is because if the “gains from trade are seen as a redistribution of income rather than as rewards to innovators for creating new wealth,” then “[s]tate authorities are more likely to impose price controls on producers and/or merchants who earn large profits than to seek ways to create incentives for others to emulate such individuals in competitive markets” (Pejovich 2003: 351). The costs, however, of institutional transition present potential profit opportunities to be monetized by institutional entrepreneurs to change the rules of game, namely, through the establishment of private property rights (Leeson and Boettke 2009; Li et al. 2006). The role of institutional entrepreneurship will be discussed in the next section.

Moreover, not only does culture matter, but ideas also matter as well, namely, through the footprint of history. For example, one of the obstacles that China encountered during the early stages of its transition to a market economy, beginning after 1978, was the “Illusion of 1957” (Cheung 1982 [1986]: 26–27). According to this illusion, the Chinese regarded capitalism to be worse than communism by equating “capitalism” with the cronyism and corruption of the rule of the Kuomintang prior to 1949, which preceded a period of economic recovery under “communism” between 1949 and 1957. “Thus within living memory the Chinese people equate capitalism with the Kuomintang *débâcle* and communism with the ‘good years’ of 1949–1957” (emphasis original, Cheung 1982 [1986]: 28). Such historical perceptions, however false and misleading they may be, may only create further institutional inertia towards a complete and credible transition to a market economy.

Given all of these difficulties inherent not only to the problem of credible commitment via signaling, but also the transaction costs inherent to institutional transition, how have some countries been able to transition to a market economy under the rule of law and achieve economic development? Peter Boettke outlines the steps that must be followed to establish a path towards successful political and economic reform: “Reform in real

time must (1) start from the existing status quo, (2) unearth the *de facto* organizing principles of that status quo, (3) design a set of reforms which address the incentive and informational problems associated with that *de facto* system, and (4) send a clear high-quality signal that the proposed reforms are credible and commit the governance structure to the new system and in doing so close the gap for the *de jure* and *de facto* organizing system in the new regime” (emphasis original, Boettke 1999: 378). In the next section, we will show how this transition has unfolded under comparative systems of federal governance, using the transitional political economy of Russia and China as comparative case studies.

Russia and China: A Comparative Transitional Analysis

One way to explain this institutional transition is to compare the transitional path that Russia and China have taken. In doing so, we make a distinction between “market-preserving federalism” (Weingast 1995; Qian and Weingast 1997) and “cartel-federalism” (Wagner and Yokoyama 2013; Wagner 2016). Under a federalist system of governance, governance is divided into two levels of authority: a national level of authority and subnational level of authority of smaller local government entities. The distinction between market-preserving federalism and cartel-federalism is based on how the national level of governance sets the conditions of competition between subnational governments.

Under market-preserving federalism, the national government credibly commits to the rule of law, namely, by allowing the entry and exit of private-sector firms to compete with state-owned firms. As a result, the wealth created through private-sector firms within competing local jurisdictions will grow, eroding the relative value of the rents derived from the political control of state-owned firms. Therefore, with the growing extension of the market, the allocation of entrepreneurial talent becomes redirected towards productive activities, rather than unproductive activities, such as rent-seeking

(Murphy et al. 1991; Tullock 1967). However, decentralization and competitive, or market-preserving, federalism are not synonymous. For example, the Soviet Union was “decentralized” in the sense that policy was administered by local governments, but local governments lacked political autonomy and local authority over the economy (Montinola et al. 1995: 57).

Under cartel-federalism, the national government creates a framework of collusion among subnational political entities. Like a cartel of firms, subnational governments collude to act as a collective monopoly, with the government acting as the *de facto* enforcer against attempted “chiseling” by local governments. In effect, cartel federalism prevents the erosion of rents derived from political control of state-owned firms and resources, namely, by obstructing the introduction of pro-growth policies among local governments that would encourage the growth of the private sector of the economy. The different institutional arrangements adopted by Russia and China since the late 1980s are reflected in their respective economic trajectories. Ten years after the transition reforms, Russia’s GDP per capita had *fallen* by almost 30% (Leeson and Trumbull 2006). The same figures had more than doubled in China over the same period of time (World Bank 2017).

Whereas Russia’s transition can be characterized by cartel federalism, China’s transition followed more closely a model of market-preserving federalism. Under a model of market-preserving federalism, China’s *de jure* changes were far less important than the *de facto* changes that emerged spontaneously among competing local jurisdictions. However, the sequence of events which we describe should not undercut “the essential element in political and economic transitions of post communism – the establishment of a binding and credible commitment to liberal limits on state action” (Boettke 2009: 43). While the emergence of private property in China was not designed by government policy, this bottom-up reform would not have flourished without a credible commitment by the state not to obstruct the *de facto* changes in property rights. After the rise of Deng Xiaoping in 1978, the “first priority under the new economic policy was

agriculture” (Coase and Wang 2012: 157). However, agricultural reform was not initiated by the *de jure* privatization of farmland. Although land is still formally owned by the state, the introduction of a “household responsibility system” has led to a *de facto* reallocation of these rights to local stakeholders.

Under this system of landownership, peasants are allowed to lease an exclusive plot from the government, leaving the responsibility contract holder to grow and sell crops of their choice. By 1982, these responsibility contracts began to be traded among peasants, and such transfers became formally permitted by the government in 1983 (Cheung 1982 [1986]: 66). The household responsibility system arose in 1978, initially out of the institutional entrepreneurship of Yan Junchang, who was a villager in Xiao Gang, a poverty-stricken village in Anhui province of China. As Li, Feng, and Jiang describe the account, “[s]truggling to escape absolute poverty, on November 24, 1978, he and 17 other farmers signed a secret agreement to divide up the land and let each household work by itself, running the risk of jail sentences. They had the implicit support of local reform-minded officials. One year later, their innovation proved to be a big success: the total grain in production was equal to the sum of production over the previous five years” (2006: 245; see also Coase and Wang 2012: 47). This *de facto* privatization of property in agriculture occurred simultaneously with the rise of commerce in special economic zones (SEZs), which was first established in the Guangdong province on August 26, 1980, to attract foreign capital and investment (Coase and Wang 2012: 62).

It is no accident that the rise of the household responsibility system and SEZs coincided with institutional reforms that limited state action in terms of taxation and regulation within Chinese provinces. Starting in 1980, China instituted a fiscal revenue-sharing system between the provincial governments and the central government. According to this fiscal arrangement, revenue income in each province is divided between a fixed shares of revenue, which is remitted to the central government, allowing the remaining share of tax revenue to remain within the local

jurisdiction (Montinola et al. 1995: 63). Moreover, the Communist Party has retained authority to appoint and dismiss governments according to their ability to foster pro-growth policies. As an added incentive, and perhaps “as an ultimate prize, the governors whose regions perform well have been brought into the national government in Beijing” (Blanchard and Shleifer 2001: 175). This choice of institutional design addressed the incentive and informational problems associated with that *de facto* system, namely, by incentivizing and selecting for those local officials whose interests would be aligned with the pursuit of pro-growth policies that encourage increased labor productivity and capital accumulation.

Although China remains undemocratic politically speaking, its ability to achieve rapid growth since 1978 could not have occurred without a credible commitment to limits on political discretion and public predation, without which property rights in land, labor, and capital would not have emerged to foster economic development. The transitional political economy of Russia, however, can be characterized by cartel federalism. Although Russia has held democratic elections and has engaged in a massive privatization scheme, such *de jure* reforms have not accompanied *de facto* reforms. This has occurred because of the failure of political officials to signal a credible commitment to the rule of law.

The Russian experience differed drastically from China's. Boettke (1993, 1995) argues that the failure of the attempts to reform the Russian economy (first under Gorbachev and then under Yeltsin) is due to that the lack of an effective rule of law. Absent the rule of law, Russian citizens had to predict whether the government would go through with reform or, instead, reverse back to centralized control of the economy and social and political life. This prediction was rooted on the historical experience with economic reform in Russia since the time of Lenin: every time the Soviet government had announced a movement towards the devolution of economic and political decision-making, this decision was then reversed in the span of years and even months. With this reversion often came the persecution of those who had taken advantage of the new economic

opportunities. It is not surprising that the Russian people did not accept the promises of the Gorbachev government at face value. Moreover, the behavior of the regime was itself sending mixed signals to the population, making the unraveling of the “reform game” even more likely. The three major pieces of legislation under *Perestroika* (the Law on Individual Enterprises, the Law on State Enterprises, and the Law on Cooperatives) aimed at increasing the competitiveness of the Soviet economy were all radically modified during the (brief) period of their implementation. “Despite the rhetoric and promise of these laws,” Boettke writes, “they contained contradictions and ambiguities that prevented them from achieving the objectives of economic reform. Furthermore, they failed to convey any binding commitment on the part of the Gorbachev regime to true market reform. From 1985 to 1991, Gorbachev introduced at least ten major policy packages for economic reform under the banner of *perestroika*, but not a single one was fully implemented” (emphasis added, 1995 [2001]: 166).

As Russia began its process of privatization during the 1990s, it did so without a complete transition of its political institutions, within which privatization takes place. Without political reform of the institutions within which political decision-making takes place, the incentives that politicians faced during the transition period remained the same. As Milton Friedman points out, “Russia privatized but in a way that created private monopolies, private centralized economic controls that replaced government's centralized controls. It turns out that the rule of law is probably more basic than privatization. Privatization is meaningless if you don't have the rule of law. What does it mean to privatize if you do not have security of property, if you can't use your property as you want to?” (Friedman 2002: viii). The inconsistency between the spirit and the letter (and application) of the reform plan only added to the skepticism of the Russian people. If the past behavior of the Soviet government suggested that its stated goals were inauthentic, its present behavior only confirmed these suspicions.

Shliefer (1997) and Blanchard and Shleifer (2001) identify another cause of Russia's reform failure, namely, its fiscal institutions, which contrast with that of China. Given the lack of the rule of law, the introduction of a decentralized political system is unlikely to lead to the desired outcome. Unlike in China, where tax revenues are raised locally, this encourages local political officials to expand their tax base by fostering economic growth. The political context in Russia, however, was best characterized by cartel federalism, since "local government revenues comes from their share in taxes collected by the central government. Moreover, while this share is in theory fixed, in practice it is negotiated. Regional governments negotiate with Moscow, and local governments negotiate with regions" (Shliefer 1997: 403), creating a collusive rather a competitive environment between regions and disincentivizing the institutionalization of pro-growth policies. Indeed, while Russia's transition has been characterized by greater *de jure* reforms than China, there have been relatively less *de facto* reforms, precisely because of a failure to credibly commit to changing the institutional incentive structure within which economic and political decision-making takes place. As Coase remarked in his Nobel Prize Address on the heels of transition of Eastern and Central Europe, "[t]hese ex-communist countries are advised to move to a market economy, and their leaders wish to do so, but without the appropriate institutions no market economy of any significance is possible" (1992: 714).

Conclusion

The problem of economic transition is fundamentally institutional in nature. For economic and political reforms to be successful in transitional economies, this entails a credible commitment to the rule of law. Absent this commitment, aligning incentives between political and economic actors becomes extremely difficult, condemning the transition process to a likely failure. The experience of postcommunist Russia and postreform China provides evidence for this hypothesis.

Trial: Implicit Biases

Goran Dominioni¹ and Alessandro Romano²

²China-EU School of Law, China University of Political Science and Law, Beijing, China

Abstract

A large body of research in implicit social cognition indicates that implicit racial biases affect human decision-making. Building on these findings, legal scholars have explored how and under which circumstances implicit racial biases affect the functioning of trial systems. This entry reviews this literature. First, it provides an overview of the main results of, and methods employed in, studies on implicit racial biases. Second, it reviews the applications of these findings for the study of criminal and employment discrimination trials and the policies that could be implemented to reduce the effect of these biases on the decision-making of the relevant actors. It concludes with some suggestions for further research.

Definition

Implicit racial biases are shifts in judgment caused by automatic and/or unconscious attitudes/stereotypes held toward a racial group. In this context, automatic means that the bias occurs without any need for attention and that it is not easily controlled. Whereas unconscious means that introspection does not reveal the attitude/stereotype.

Introduction

In the last decades, studies in behavioral economics and psychology have highlighted the existence of various behavioral patterns that are inconsistent with the rational choice theory (Kahneman 2011 and references therein). Legal scholarship has

highlighted that many of these patterns are relevant for the study of law and policy-making (Jolls et al. 1998). Part of this literature, and especially in the context of trial settings and employment law, focuses on implicit biases (e.g., Jolls and Sunstein 2006; McAdams and Ulen 2009; Teichman and Zamir 2014). Although implicit biases do not relate only to race (but, for instance, also to gender), the wide majority of studies on this topic within behavioral law and economics focus on this particular issue. For this reason, the scope of this entry is restricted to implicit racial biases.

Scientific Basis and Research Methods

Two core concepts in the study of implicit biases are attitudes and stereotypes.

An attitude is a mental association between a racial group and an evaluative disposition (Greenwald and Krieger 2006). This evaluative disposition can be either positive or negative. For example, a person may hold either a positive or a negative attitude toward Asians. Instead, racial stereotypes are an association between a racial group and a positive or a negative characteristic (e.g., being lazy, good in math, or aggressive).

Research on implicit social cognition has studied the relationship between attitudes and stereotypes both at the implicit and the explicit level. This literature indicates that a person can hold an implicit attitude and a stereotype that point in opposite directions. For instance, it is possible to have a negative attitude toward Blacks and yet hold a positive stereotype toward them (e.g., Blacks are good in sports). In addition, existing evidence indicates that self-reported attitudes and stereotypes do not necessarily mirror implicit measures. As a consequence, it is possible for an individual to hold, and maybe act upon, an implicit attitude or stereotype that conflicts with the ones she consciously endorses (Greenwald and Krieger 2006).

Implicit attitudes and stereotypes are identified using implicit measurement procedures. Thanks to these techniques it is possible to identify attitudes and stereotypes that, for a variety of reasons, self-reporting may fail to detect

(e.g., unawareness). Among the most commonly used techniques to measure implicit biases, there are affective priming, the implicit association test (IAT), and brain imaging.

In affective priming, subjects are exposed to two types of stimuli – a target and a prime – and they are asked to categorize the target as either positive or negative. To perform the task the only relevant stimulus is the target; therefore the prime should not affect the behavior of the subjects. For instance, in studies on implicit racial attitudes, subjects are first exposed to pictures of Black faces and White faces (the prime). This exposure occurs subliminally, meaning that pictures are shown for a very short time (e.g., 200 ms), so that they are processed only unconsciously. Subsequently, subjects are exposed to a series of words (the target) and are asked to categorize them (positive/negative). When priming with a racial stimulus that facilitates the categorization of the words as negative, the subject is said to hold a negative attitude toward the group (Fazio et al. 1995).

Another widely used measurement procedure in the implicit biases literature is the IAT (Greenwald et al. 1998). This procedure allows testing the relative strength of implicit attitudes and stereotypes via the measurement of response latencies in the categorization of stimuli into classes. In particular, in a racial IAT, part of the stimuli relates to racial groups (e.g., a name more commonly associated with a Black/White person), while the remaining stimuli relate to other concepts (e.g., good/bad). Subjects are repeatedly asked to categorize each stimulus (e.g., a Black name) as belonging to one of two dyads. Thus, for instance, subjects are first asked to categorize good/bad concepts and Black/White names as belonging to either the Black/good or the White/bad dyad. And, subsequently, the task is repeated with Black/bad and White/good dyads. Differences in response time between different combinations of dyads indicate that a certain racial group is more easily associated with a certain concept.

Another technique often employed in the implicit racial attitude domain is blood-oxygen level-dependent contrast imaging in functional magnetic resonance imaging (Fazio and Olson

2003). This physiological measure identifies variations in oxygen levels in the blood present in different parts of the brain, which are positively correlated with activations of these areas. Thus, for instance, exposure to Black faces has been shown to generate a greater activation of the amygdala (the amygdala is a part of the brain related to the processing of emotions). Therefore, this strand of research indicates that the exposure to different racial groups can trigger distinctive emotional states (Kubota et al. 2012).

Main Findings

The existing research indicates that implicit racial biases are pervasive in the White population of several Western countries. The largest database regarding the diffusion of implicit biases comes from the online platform Project Implicit, which allows visitors to take a racial IAT online. An analysis of the data gathered on this platform between the years 2000 and 2006 indicates that more than 65% of the people who took the racial IAT associated relatively more easily Blacks with bad. In addition, less than 15% of the participants (mainly non-White subjects) held relatively stronger associations between White and bad.

This data also suggests that Blacks are the only racial group that do not show strong pro-White associations (Nosek et al. 2007).

Research in implicit social cognition indicates that various factors mediate the formation of implicit biases. In particular, empirical evidence indicates that implicit biases can stem from past (often forgot) experiences, which may date back to early childhood. These experiences can be either direct or indirect. As indirect experiences – for instance, via the media – generally contribute to the formation of a negative perception of Blacks, this could explain the absence of a pro-Black bias among Black people (Greenwald and Krieger 2006).

A large part of the literature on implicit biases analyzes their impact on human behavior (both spontaneous and deliberate). Two meta-analyses on racial IAT studies find that measurements of implicit biases have a higher predictive validity

than self-reported measures (Greenwald et al. 2009; Oswald et al. 2013).

A meta-analysis of racial priming studies reaches a similar conclusion (Cameron et al. 2012). Overall, this literature suggests that implicit biases can affect behavior, making them especially relevant for the study of discrimination in trial settings. In this regard, it is important to notice that even small effects size for a single decision can predict large discrimination at the societal level, especially when the bias affects many individuals or when it repeatedly affects one individual (Greenwald et al. 2015).

Applications in Trial Settings

Having introduced the background of the topic, let us now analyze how implicit biases relate to trial settings from a law and economics perspective. Broadly speaking, existing research on implicit biases in trial settings unfolds in two directions. First, studies in implicit social cognition made their ways into law reviews because of the impact that implicit biases have on trial actors' behavior. Second, implicit biases have been widely discussed among legal academics in relation to the epistemic value of implicit measurements in the context of evidence law. The second line of enquiry is *sensu stricto* not behavioral and is thus less relevant for the present discussion. In the following, we will therefore focus only on the behavioral side of the debate.

Implicit Biases and Trial Parties Decisions

Earlier law and economics literature depicts trial participants (judges, prosecutors, and lawyers) as rational agents that allocate resources following a rational calculation of the costs and benefits of their actions (McAdams and Ulen 2009). For instance, according to the efficient prosecutor model, the prosecutors maximize convictions (and attach different weights to different sentences) or seek deterrence maximization (Garoupa 2012). Later developments in the field questioned this simplistic description of trial participants and emphasized the role of institutional details and behavioral aspects of human decision-making.

Research on implicit biases is a subset of these developments.

With few exceptions, research on implicit biases in the courtroom has focused on criminal trials (Kang et al. 2012). In these settings, a figure that plays a major role in steering the unfolding of a trial is the prosecutor. Research suggests that implicit racial biases among prosecutors account for at least part of the disparities in incarceration rates between racial minorities and nonracial minorities in the US criminal law system (Smith and Levinson 2011; Kang et al. 2012). And indeed, implicit biases can be particularly effective in distorting human behavior when confronted with decisions that have the following characteristics: (i) allow for some discretion, (ii) have to be taken quickly, and (iii) do not provide accountability mechanisms. The decisions taken by prosecutors often present all these characteristics. A typical example is the decision on whether to charge a suspect or what crime to charge. In these cases, implicit stereotypes may influence prosecutors' decisions to the disadvantage of racial minorities. For instance, empirical evidence indicates that many individuals tend to have a stronger implicit association between Blacks and aggressive behaviors than between Whites and aggressive behaviors. Similarly, at the implicit level, Blacks are often more easily associated with guns than Whites. Smith and Levinson (2011) argue that these stereotypes may influence the decision of a prosecutor regarding whether to charge a crime both when the Black person is the alleged victim and when he is the alleged perpetrator. For example, following a shooting, prosecutors may have to decide whether to justify the act for self-defense. When the alleged perpetrator is Black and the victim is White, the bias might make it more plausible in the mind of the prosecutor that the harm caused by the Black was the product of an unjustified aggressive behavior. Instead, when the victim is a Black person the stereotype may lead the prosecutor to believe that his aggressive behavior may have justified the actions of the White person under investigation (Smith and Levinson 2011).

Another strand of literature focuses on defense attorneys. On this regard, the concern is twofold.

On the one hand, implicit biases may induce a defense attorney to not defend a Black client. This, for instance, may occur when the attorney undervalues the probability of winning a case at trial on the basis of a biased evaluation of the available evidence. On the other hand, implicit biases may impair the performance of an attorney by undermining trust and communication with the client. Contextual factors such as work overload and degree of discretion may enhance the effect of implicit biases on attorneys' decisions. Incidentally, US public defenders often operate with insufficient resources to properly fulfill their tasks (Richardson and Goff 2013). Eisenberg and Johnson provide evidence of the pervasiveness of implicit biases among US defense attorneys (Eisenberg and Johnson 2004).

Most importantly, implicit biases may affect adjudicators' judgment and decision-making. And indeed, empirical evidence indicates that the judgment of both jury-eligible citizens and judges is affected by implicit biases (Hunt 2015; Kang et al. 2012). Regarding judges, Rachlinski and coauthors find that racial IAT scores among 120 US judges show similar patterns to those gathered with other samples. In particular, in line with the results obtained on the Project Implicit platform, they find that the large majority of White subjects held implicit attitudes that favor Whites over Blacks, while Black judges did not show strong preferences toward a particular racial group. The study further shows that when judges are not sufficiently motivated to control them, implicit biases affect their judicial decisions (Rachlinski et al. 2009).

Implicit biases can influence adjudicators' decisions from a number of perspectives, and in particular when judges have a relatively higher degree of discretion. Therefore, the influence of implicit biases might be more pronounced when the evidence presented by the parties is ambiguous (Kang et al. 2012). Hence, it is reasonable to conjecture that the effect of implicit biases might be more severe in civil cases, due to the lower burden of proof. In addition, implicit racial biases can affect memory recalls by leading adjudicators to remember facts in a more stereotypically consistent manner (Levinson 2007). In this regard, a

growing strand of literature is highlighting the existence of various implicit stereotypes that are of particular relevance in a criminal trial context. For instance, various studies suggest the existence of an implicit and bidirectional association between Blacks and crime (Hunt 2015). Similarly, Levinson and coauthors show the existence of a stronger implicit association between Blacks and guilt than Whites and guilt (Levinson et al. 2010). Importantly, IAT scores gathered with this measurement procedure predict evaluations of items evidence in a hypothetical trial. Along similar lines, in the context of death penalty judgments, implicit associations between racial groups and value of life have been shown to predict higher rates of death penalty punishments against Black defendants (Levinson et al. 2014). On a related note, implicit biases may partially account for the relatively higher rates of death penalty sentences inflicted to persons of color. For instance, implicit biases may ease finding the behavior of an offender as being heinous, atrocious, or cruel, which is one of the aggravating conditions under which death penalty can be inflicted under US law (Smith and Cohen 2012).

Outside the criminal law sphere, legal scholars have discussed implicit biases in the courtroom mainly with regard to employment discrimination lawsuits (Kang et al. 2012; Gertner and Hart 2012). In this context, the literature mostly focuses on the criteria that US judges are expected to adopt when deciding the dismissal of a case in its early stage. Here, the main concern regards the *Iqbal* standard, under which a judge should dismiss a case when the intent to discriminate the employee is not the most plausible explanation for the conduct of the employer.

In making this evaluation, the standard encourages judges to use their common sense. In this regard, legal scholars argue that, by asking judges to rely on common sense to make this decision, the law facilitates the influence of implicit biases on trial outcomes (Kang et al. 2012; Gertner and Hart 2012).

Debiasing and Insulating

Given the relevance of implicit attitudes and stereotypes, researchers are exploring how to

decrease or eliminate their influence on trial actors' decision-making. From a general perspective, these interventions can act either on trial actors' general tendencies to be influenced by these biases or on the environment in which trial decisions are made.

One way to decrease the influence of implicit biases on the general decision-making of trial participants is via training (Rachlinski et al. 2009; Kang et al. 2012; Smith and Levinson 2011; Teichman and Zamir 2014). This training may aim at increasing awareness among trial actors about the existence of implicit biases. In turn, this may have the positive effect of decreasing actors' overconfidence in the objectivity of their own judgment while increasing their motivation to control the biases. Various studies in psychology confirm that motivation to control implicit biases can be effective in reducing their influence on behavior, and hence jurors should be advised to take the perspective of the out-group person (Kang et al. 2012). Rachlinski and coauthors further suggest that judges should take a racial IAT (Rachlinski et al. 2009). Beside increasing awareness, this may have the positive result of providing judges with a rough estimation of their biases and may therefore help them taking decisions regarding the training they may need as well as avoid overcorrections (i.e., shifting the bias against Whites).

Another strategy to reduce the impact of implicit biases is exposing trial actors' to counter-stereotypical information or increasing their contacts with members of racial minorities (Rachlinski et al. 2009; Kang et al. 2012; Smith and Levinson 2011). An obvious path is increasing racial diversification in the courtroom and in prosecutors' offices. However, this can only be effective as a long-term strategy. In the short term, debiasing can be attempted by introducing images of positive figures of minority members in judges' offices.

Alternatively, interventions could focus on the context in which decisions are made. For instance, trials could be structured so that trial agents are given sufficient time to make their decisions. And indeed, this could reduce their reliance on automatic processes and thus the influence of implicit

biases on their decision-making. Similarly, research indicates that conditions of high cognitive load (i.e., situations in which the cognitive activity imposed on working memory is high) ease the influence of implicit biases on judgment. Therefore, various authors suggest trial actors to adopt strategies that may reduce cognitive load when making decisions (Kang et al. 2012). Additional strategies include hiding racial information in the file that prosecutors use to decide whether to charge for a crime (Smith and Levinson 2011) and increasing jury diversity (Kang et al. 2012). In fact, research indicates that racially diverse juries tend to endure more thorough deliberations than all-White juries. In turn, this may reduce the reliance on automatic processes in decision-making.

Accountability can also play a role in reducing the effect of biases. For instance, it has been proposed that prosecution offices could gather data regarding the racial composition of individuals at each stage of the charging phase to provide useful feedback to prosecutors (Smith and Levinson 2011). Similarly, judges could keep track of their decisions, in order to spot potential systematic biases in their decision-making (Kang et al. 2012; Rachlinski et al. 2009). Another path to increase judges' accountability is increasing the depth of the scrutiny allotted to appellate courts in situations where the racial composition of the court of first instance fuels the suspect that the decision might be biased (Rachlinski et al. 2009).

Potential interventions to reduce the effect of implicit biases at trial are however not limited to public institutions, as also attorneys can implement strategies to help them overcome their biases. Public defenders could refer to objective standards for triage and checklists to evaluate their cases. These measures may help attorneys to impose clearer limits to their own discretion (Richardson and Goff 2013).

Future Directions

As discussed in this entry, studies in implicit social cognition can provide many insights on trial dynamics and remedies to contrast racial discrimination in the courtroom. Yet, this field of

research is one of the latest developments of the already relatively young field of behavioral law and economics. Therefore, there is still a lot to learn on how these biases operate and how they influence the overall efficiency of the legal system. In the following, we highlight various possible pathways for future research.

First, it is still unclear how implicit biases affect the efficiency of legal systems. In particular, this strand of research can analyze how, to what extent and under which circumstances, implicit biases affect system costs related to criminal investigations, litigation, and adjudication. In addition, by influencing trial actors' behavior, implicit biases also affect the primary incentives provided by the law outside the courtroom (on a similar note see McAdams and Ulen (2009)). Last, as courts' accuracy is widely acknowledged as an essential element for the achievement of deterrence (Kaplow 1994), it is particularly relevant to study how implicit stereotypes affect accuracy in adjudication.

Second, the literature on implicit biases at trial mainly concentrates on Blacks (and Whites). However, the USA and other countries are becoming prismatic societies, and therefore more attention should be given to other racial and ethnic groups (e.g., Hispanics and Asians). Moreover, European scholarship and policymakers could benefit from research conducted on implicit discrimination against Arabs, Eastern Europeans, and Roma people. Along these lines, it might be warranted to conduct some studies on implicit stereotypes against Black people in Europe. In fact, as implicit biases are partially a product of culture, it might be interesting to study cross-cultural variations in implicit stereotypes.

Another pathway of research that remains largely unexplored regards implicit biases in non-criminal settings (Teichman and Zamir 2014). In particular, there is the need for further research in the fields of civil and administrative law. For instance, it has been argued that implicit biases may affect the application of the standard of proof in civil cases (Hunt 2015). Yet, these hypotheses await testing.

Future research can also contribute to a better understanding of debiasing mechanisms. As

shown above, the existing literature has started delving in this direction. Results reached so far are informative, but it is still not clear whether, and to what extent, these interventions are effective in real-life settings (Teichman and Zamir 2014). For instance, as discussed above, one of the main recommendations to decrease implicit biases among judges relates to increased diversity in judicial bodies. Yet, Rachlinski and coauthors found little differences in the pervasiveness of implicit biases between groups of judges coming from jurisdictions with great differences in racial diversity in the judiciary (Rachlinski et al. 2009). Further research could explore in more depth the conditions under which policies aimed at reducing implicit discrimination at trial are more likely to succeed.

Last, with few exceptions, most studies on implicit biases in the courtroom have been conducted with students. The field would benefit from having research conducted with professionals involved in trials. In particular, on the one hand, it would be interesting to gather data regarding the pervasiveness of implicit biases among trial agents. On the other hand, it would be important to analyze whether expertise affects the degree by which implicit biases impact behavior in trial settings.

enforcement. Retrieved from understanding the WTO: the agreements: http://wto.org/english/thewto_e/whatis_e/tif_e/agrm7_e.htm).

This entry considers this balance by looking at the two poles of intellectual property policy: providing incentives to increase innovation and optimizing access to inventions both for consumptive use and for potentially innovation-increasing experimentation. This entry also surveys the notion of *calibration*, the idea that every country or region should adapt its regulatory framework to reflect its own strengths and weaknesses in optimizing what one might refer to as its innovation policy. A calibration approach suggests that providing innovation incentives and optimizing access are not mutually exclusive objectives.

TRIPS Agreement

Daniel Gervais
Vanderbilt Intellectual Property Program,
Vanderbilt University Law School, South
Nashville, TN, USA

Abstract

The Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS Agreement) was negotiated between 1986 and 1994 during the Uruguay Round of the General Agreement on Tariffs and Trade (GATT), which led to the establishment of the World Trade Organization (WTO). The TRIPS Agreement sets minimum levels of several types of intellectual property (IP) protection, including copyright, trademarks, patents, industrial design, and trade secrets protection. Membership in the WTO includes an obligation to comply with the TRIPS Agreement. According to the WTO, the Agreement attempts to strike a balance between long-term social benefits to society of increased innovations and short-term costs to society from the lack of access to inventions (World Trade Organization (n.d.) Intellectual property: protection and

Part I: Incentivizing Innovation and Optimizing Access

The TRIPS Agreement has become the rope in the tug-of-war between utilitarianism and egalitarianism. Much of the Western intellectual property system seems to be based on a utilitarian theory regarding which IP rights should be given in order to incentivize the creation of new and potentially commercially valuable knowledge, referred to as “informational goods.” This expression is meant to capture goods and related services that derive all or most of their value from the information they contain or embody.

As IP rights and protection standards increase, problems regarding access to existing informational goods arise. A maximalist utilitarian argument might be that there should be no right to access new informational goods because these goods would not have existed in the first place *but for* the existence of adequate IP rights. A more nuanced utilitarian approach might allow for some unlicensed use of certain informational goods, notably to maximize the continuing production of knowledge. Of course, in an optimal policy scenario, allowing for unlicensed uses of new goods should be done in a way that does not negatively affect incentives to innovate (Chandler and Sunder 2007). Egalitarianism, by contrast,

focuses mostly on distributional issues, notably access to new knowledge and goods.

Utilitarian and egalitarian objectives are not incompatible. In fact, incorporating egalitarian or distributive concerns into the utilitarian conversation can lead to the design of a system where both production and access are considered equally valid objectives. Unfortunately, discussions regarding the TRIPS Agreement have tended to focus either on the failure to produce sufficient incentives to innovate (i.e., the failure to supply an optimal supply of new informational goods) or on the failure to provide access to potentially life-changing and life-saving inventions. Both utilitarian and egalitarian perspectives are legitimate. From the utilitarian perspective, if new inventions or creations would not have existed *but for* the IP incentive, then negatively affecting incentives to innovate has adverse welfare impacts, including on economic development. This valid utilitarian argument can coexist with an equally valid egalitarian argument: in situations where markets fail to produce the optimal supply of the demanded informational goods due to anticompetitive practices or transaction costs, access may be improved by the use of appropriate exceptions to and limitations on IP rights, including compulsory licensing. In this scenario, access to these goods may be optimized without negatively impacting incentives to innovate in a significant way.

How does one strike the right balance of creating the incentives to enable or accelerate the development of new technologies and not restricting those technologies unduly when there is no real market to protect (e.g., in the case of a public good)? An economic analysis of IP law and policy makes it possible to dispel the normative fog of utilitarianism or egalitarianism, in which many legislative and judicial decisions are steeped. An economic lens offers novel ways of envisioning public actions and allows for the possibility of moving beyond inconsistencies and sticking points (Josselin and Marciano 2001). Striking the right balance requires the determination of what affects the value of an IP right, particularly what reduces that value.

Reduction of value may follow from granting (or even the threat of granting) a compulsory

license or eliminating the right to exclude in a certain context by granting a limited legislative or court-made exception to allow for the free use of the protected creation or invention. While limiting exclusive rights may result in the reduction of the value of an IP right, it also allows third parties to understand, copy, and potentially improve on the subject of the IP right. The equilibrium between protecting the value of an IP right and optimizing the production of the protected informational good is difficult to achieve.

The Parameters of IP Policy Equilibrium

Normative debates based on the definition of property rights rarely provide a full answer to the policy question of balance outlined above. Intellectual property usually bears *aspects* of a property right, notably the right to exclude others, but that right is often much more limited than a full ownership right in a tangible object (Waldron 1988; Mackaay 1994). Consider the law of trademarks. It requires proof of a risk of confusion on the part of the potential purchaser before the right to exclude can be applied. No comparable requirement exists with respect to tangible objects. In the same vein, exceptions to the right to exclude such as fair use in copyright law, compulsory licensing of copyrights or patents, or experimental use of a patented invention without permission provide evidence of the varying nature of informational goods and of the relative nature of IP rights. Policy equations must reflect these differences.

The impossibility of determining the exact degree of overlap between property rights (in the classical sense of the term) and IP rights is not an outright impediment to striking an efficient policy balance using economic analysis. A list of objectives that is fairly persuasive can be drawn up: (1) the creation of sufficient incentives to innovate, (2) the efficient functioning of the markets for copyright works and patented inventions embedded in informational goods, and (3) the optimal (or at least reasonable) access to works and inventions. A fourth objective should be added, namely, the recognition (or attribution) of the work to the creator or inventor. An attribution right can be justified as useful for the author or inventor in generating goodwill but also as

providing users with information on the source of the good (e.g., name of the author, trademark of maker or supplier). A user can use this information to attribute trust value to the attributed source and thus possibly have decreased search costs in future transactions concerning the same good.

In order to achieve an equilibrium, IP policy equations must be solved in a way that meets the aims of all the interested parties – including creators, inventors, firms, investors, users, and reusers. The parameters of the solution allow for the perception of an adequate level of foreseeability for every group of stakeholders:

[I]ntellectual property rights, like other property rights, set the parameters allowing investors to make a guess of the expected revenues. Only once these parameters are set will investments be undertaken. (Mackaay 1994)

Economic analysis leads policy-makers to set objectives, the achievement of which can be measured by concrete results rather than fulfillment of ideology.

Compulsory Licenses

An option to maximize access to and use of the invention or creation is to issue compulsory licenses. These licenses typically involve the payment of remuneration (determined to be adequate by competent authorities) and reporting requirements (amount made, used, exported (if any), etc.). Issuing compulsory licenses constitutes the establishment of a liability regime (instead of an exclusive right) (Reichman 1992).

Compulsory licensing is allowed under the TRIPS Agreement (World Trade Organization 2014). The debate regarding compulsory licenses, which has been on top of the agenda in international IP law and policy for decades, is centered on access to inventions but also on negative impacts on incentives to innovate. In this debate, the unfairness of the patent regime for indigent users who cannot afford new medicines is often emphasized; poor countries may only be able to procure new medicines at the expense of other urgent developmental priorities (i.e., at the expense of the production of other public goods).

Compulsory licenses may improve private parties' access to informational goods and help

to achieve efficient outcomes when markets are working suboptimally in providing access, especially when access to the informational good concerned is considered necessary (e.g., pharmaceuticals or educational materials). Governing bodies issue compulsory licenses typically to allow the use of an informational good either to increase access or, second, in the hopes that third parties will make improvements or invent new products, which, in turn, will lead to competition in the market where the IP right owner is operating. The risk is the systemic weakening of incentives to innovate. If the price paid is considered too low, then financial incentives may be negatively impacted. This is also true if the instituted exception interferes with the markets operating in other territories. For example, one who purchases products at a lower cost due to a compulsory license should not export the products to another territory; such a practice may disrupt the market of the other territory. The holder of an exclusive right might also experience a reduction in the value of that IP right if a competitor were able to use the subject of the exclusive right without permission from the holder.

Compulsory licensing is subject to two additional caveats. First, knowledge that would be transferred with a *voluntary* licensing agreement may not accompany a *compulsory* licensing scenario. This knowledge may not be disclosed or otherwise “enabled” (meaning that a person with requisite knowledge can understand how to make and use the invention from the information disclosed in the patent) by the patent subject to the compulsory license. Second, a firm subjected to a compulsory license may withdraw, delay, or cancel other investments in the country. These are factors to bear in mind before issuing compulsory license. Their relative weight in the decision will vary case by case.

The Specific Case of Cultural Goods

There are economically relevant cultural aspects to the creation of incentives to innovate in the literary and artistic fields. Problems of incentives and access can impact the creation and viability of industries that produce and market cultural informational goods. Additionally, IP rules can negatively impact access and use of such goods.

Incentives to innovate are linked to the size of potential markets for new goods, which in gross economic terms would factor in the number of prospective users and their financial ability to purchase “cultural goods,” which are a subset of informational goods more directly linked to cultural and entertainment industries, such as films, music, and books in various formats. This explains the importance of English – and specifically of the North American market – in this context. Because many buyers in those regions can afford to purchase many cultural goods, they create a solid market for English-language informational goods and thus an incentive to produce such goods. The role of English as a second language in many other parts of the world reinforces this feature.

When goods are produced for markets where prices are comparatively high, they may not be made available at lower prices in other markets, in part because price discrimination may lead to exports from lower-priced markets to higher-priced ones. Such exports may be unauthorized by the copyright holder but still legal in countries that allow “international exhaustion,” namely, the ability to import in their territory goods legally produced in other countries. The TRIPS Agreement contains no mandatory rule on exhaustion.

In 1971, an appendix was added to the main international copyright instrument, the Berne Convention. This appendix allows compulsory licenses to be issued for the translation and reproduction of foreign books in developing countries in order to increase access to knowledge. Developing countries, particularly their education systems, may not have the economic ability to purchase cultural goods in sufficient quantity to validate the incentive to innovate protected by the IP system. Because some developing countries do not have sufficient buying power (compared to more industrialized markets), they would not contribute to the monetary award that the IP right entitles the creator of the work to receive. The ability to issue compulsory licenses for translation has in fact been one of the most contentious issues since the early days of the Berne Convention.

Part II: Calibration Within TRIPS Parameters

Changes to the TRIPS Agreement and the adoption and implementation of new wide-ranging multilateral treaties are unlikely and perhaps decades away. In fact, it took over a decade to pass Article 31*bis*, the only amendment to the TRIPS Agreement thus far. Therefore, at this juncture and for the predictable future, the calibration of IP policy will remain mostly a matter of domestic policy-making and regional trade agreements. Calibration will most likely involve using flexible provisions contained in TRIPS (i.e., the specific exceptions and limitations) or interpreting the Agreement to achieve IP policy goals. For example, courts may interpret the Agreement to include fair use/fair dealing exceptions to copyright rights and setting of appropriate limits on patentable subject matter.

Structurally, calibration is not a rejection of the harmonization mentioned in the opening paragraph. The calibration approach recognizes that rules will vary to a certain degree due to differences among regions, countries, and industries. This approach suggests that variations within parameters set by TRIPS are *desirable*. Calibration suggests that, by developing a comprehensive IP strategy focused on innovation and welfare improvements, a country can limit the negative impact of transitioning to more rigorous IP protection and increase its chances of reaping the benefits thereof, including technology-related foreign direct investment (FDI) and growing domestic Web-based, pharmaceutical, and other technology-intensive industries.

The Calibration Process

How does one design a calibrated implementation of TRIPS as part of an innovation optimization strategy? One can begin by eliminating what is unlikely to work. For example, there are probably no definitive answers given to questions such as whether the optimal term for a patent is 12, 18, or 22 years. All one can say is that, beyond a certain point, patent protection *decreases* innovation (Gallini 1992). Empirical studies have verified that in countries without the necessary technology-

absorptive capacity, increasing patent protection for pharmaceuticals produces little, if any, innovation outcomes (La Forgia et al. 2009). Similarly, in the copyright realm, there are no definitive answers to how long IP protection should last. Is the optimal copyright term 14 years from publication or the life of the author plus zero, 50, or 70 years? (Sprigman 2004). What combination of rights and exceptions would better achieve the policy goals than rules in place now? Is using a *single* term of protection part of the problem? One could argue that for a certain invention (protected by patent) or creation (protected by copyright), one specific term is optimal while a different term is more appropriate for another invention or creation (Stanley 2003). Finding the optimal point of IP protection is difficult because each informational good might require a different level of protection. Thus, horizontal rules (such as a single term of protection or bundle of rights) are approximations at best. These policy discussions can take the form of continuous imprecise balancing acts, making it difficult to reach a calibration target (Falvey et al. 2004).

Instead of engaging in *systemic* analyses to issue bright-line rules (e.g., patent protection lasts 20 years), policy-makers could try the other extreme, that is, a full case-by-case approach. Such an approach would factor in the exact value added of *each* informational good. Value determination would then depend on measuring the exact size of the inventive step involved in the invention concerned. This is related to the issue of measuring *patent quality*, and various metrics have been proposed, including by the Organisation for Economic Co-operation and Development (“OECD”), by considering how many times a patent is cited in later patents (Organisation for Economic Co-operation and Development 2011). Such measurements often emphasize the need to move policy goals away from purely quantitative patent metrics (number of applications or grants) and focus on the quality of the information disclosed.

One could add to this equation the degree of competition in the industrial or economic sector impacted by the invention and, relatedly, the number of dominant players by market share (Hollis 2004). Even if such a case-by-case approach did

not encompass high transaction costs, experts could only estimate the future utility of the invention. In terms of predictability, time, and transition/protection costs, a system of copyright or patent with a single set of rights and one term of protection may therefore be better than case-by-case analysis. While perhaps theoretically less attractive, such a system is simple to understand and easy to administer.

Does this mean that one is stuck at the abstract level without any hope of achieving relative analytical clarity? Here, TRIPS only offers normative guideposts and guarantees minimum levels of protection. In implementing TRIPS, each country or region should calibrate its IP policy recognizing its own unique characteristics and needs.

Calibration by Region and Industry

Both the systemic and case-by-case approaches are suboptimal for the aforementioned reasons. A more realistic approach for policy-makers trying to effectuate calibration revolves around the level of rights and exceptions that, *within the range of TRIPS-compatible implementations*, is most likely to achieve the policy goal of maximizing innovation while minimizing negative welfare impacts. Because the TRIPS Agreement only “harmonized” national laws to a degree, it left space for calibration (Reichman 2000). One should use a combination of human *and* economic development factors in order to craft a set of objectives to help determine the best level of rights and exceptions. These objectives will be amenable at least to the kind of metrics (e.g., the United Nations Human Development Index) that evidence-based policy-making calls for. Development is “a pseudonym for a complex network of benefits associated with economic growth and human social capital” (Okediji 2009). It is the sum of the changes in social patterns and norms through which production devices couple with the population: the latter acquires the capacity to utilize the former in order to achieve what is considered to be a satisfactory growth rate, and the production devices supply products that serve the population instead of being “alien” to the population. This dialectic of production devices

and population is the essence of development (Perroux 1988).

Establishing broad developmental goals is not the same as implementing them. Each country implementing TRIPS must recognize how it compares to others in the region or countries elsewhere at a similar level of development.

Differences Among Countries

Developing countries are not all identical; in fact, they are far from identical. Developing countries can be grouped in various ways. Leaving aside the least developed countries (LDCs), for which TRIPS obligations have been suspended, one could distinguish developing countries via a “net outcomes” approach. Countries in which innovation benefits outweigh additional rent extraction can be grouped together, and countries in which additional rent extraction outweigh innovation benefits can be grouped together. Professor Llew Gibbons offers a promising taxonomy of developing countries (Gibbons 2011). He grouped these countries according to three stages of development:

Stage One

- Foreign direct investment is rare and usually limited to specialized sectors – often relating to the exploitation of natural resources or developing franchise service industries like a major international brand bottling company.
- There exists unskilled, cheap labor.
- Foreign businesses create the necessary infrastructure and invest in human capital.
- The developing country is investing in the training of skilled workers and junior managers. Successfully developing a skilled workforce is a prerequisite to entering stage two.

Stage Two

- The economy is now able to absorb technology, to imitate technology at some level, and to contribute minor improvements.
- There exists a well-educated workforce adapted to absorb new technology from other countries and then incorporate the technology into the domestic economy.

- Domestic research efforts are primarily facilitative or associated with technology transfer. Focus shifts gradually to efforts on more innovative projects.

Stage Three

- The newly industrialized country produces its own intellectual property.
- The country is very selective as to which IP rights it zealously protects.

This progression from imitation to absorption to innovation tracks the path proposed by innovation theorists, i.e., progression from imitation to adaptation to true global innovation. Countries have indeed followed the progression described; along the pathway of development, the countries have gradually created more IP rights and made better use of existing IP rights. As countries build innovation-focused industries, they generally develop more sophisticated and nuanced IP policies (Gervais 2005). Simply put, they play the IP game better.

Differences Among Industries

The TRIPS Agreement put all industries on the same footing. Yet, treating all industries as equally sensitive to IP protection is incorrect and results in a number of unintended consequences. First, there is a relatively short list of industries generally considered to be highly patent sensitive. The list includes industries consisting of certain chemical companies, producers of laboratory instruments, and makers of steel-mill products (Cheng 2012; Maskus 2000; Gervais 2005). This list is partially derived from Mansfield’s studies of the field, in which he found that while 90% of pharmaceutical innovations were dependent on patent protection, only 20% of electronics and machinery innovations were patent dependent (Cheng 2012; Mansfield 1986). Beyond the general consensus on the patent dependency in these aforementioned fields, controversy concerning the role and impact of patents on innovation quickly emerges. Do the benefits from patents to computer software and online commerce outweigh the costs of obtaining, enforcing, and defending against patent infringement claims, especially those brought by

nonpracticing entities? (Mullin 2013). This question is front and center in a number of both developed and developing countries (Shrestha 2010). Proposals to recognize differences in industries have been made in the United States. For example, some scholars suggest that if the legislator is unwilling to separate industries by applying different standards, then perhaps courts should (Burk and Lemley 2010). In a developing country, implementing a *single* patent policy for *all* industries – as is facially required by TRIPS – may thus be structurally suboptimal.

While the TRIPS Agreement identifies uniform patentability criteria, the question whether it makes sense to treat all industries the same should be on any comprehensive innovation agenda. A form of “discrimination” based on the nature of the industry concerned would be justified if one could develop a proper metric to measure whether and how innovation outcomes are achieved.

Conclusion

As policy-makers around the world navigate deeper in the calibration waters of TRIPS implementation and seek to optimize national innovation strategy within the boundaries ascribed by TRIPS, they must attempt to avoid the negative consequences of increasing IP protection, from patent trolls, and the prevention of access to essential medicines by patents to the chilling of free expression and prevention of fair uses by copyrights and trademarks. While avoiding the Scylla of excessive IP, one must also not run to the Charybdis of insufficient IP. This is the inevitable and desirable process of calibration that an economic analysis of IP law can both inform and guide.

Type-I and Type-II Errors

Matteo Rizzolli

LUMSA University, Rome, Italy

Abstract

Adjudicative procedures meant at establishing truth about facts on defendants' behavior are naturally prone to errors: defendants can be found guilty/liable when they truly were not (type-I errors) or they can be acquitted when

they should have been convicted (type-II errors). These errors alter the incentives of defendants to comply with norms. We review the literature with a particular focus on type-I errors.

Introduction

The word *adjudication* has its Latin roots into the words *jus* (right, justice) and *dicere* (to say). All organizations set goals and have adjudicative procedures to “establish the truth” about members' compliance. Performance appraisal committees decide whether employees earn rewards within business organizations; teachers must assess students' progress in learning; courts adjudicate whether citizens have committed crimes; disciplinary committees within sport leagues and professional organizations as well as religious tribunals assess whether members' conduct has been conforming. Adjudicative procedures must evaluate and reward something they cannot directly observe – being it effort, intention, or act – and this makes them obviously prone to errors. Although our framing will be mostly applied to criminal (See also ► “[Criminal Sanctions and Deterrence](#)” and ► “[Crime, Incentive to](#)”), administrative, and civil courts, most of the results here presented apply to any generic adjudicative procedure. We thus consider the general case of an adjudicative authority who (i) must assess whether the observed behavior of an individual *conforms* or *deviates* from the prescribed behavior and (ii) must incentivize or sanction such behavior accordingly. In judging behavior, errors inevitably arise, and they generally undermine individuals' incentives. These errors take mainly two forms: (i) the adjudicative authority may assess non-compliance when in fact the subject is duly complying and (ii) the adjudicative authority may assess compliance when in fact the subject is deviating. Individual's compliance with the prescribed behavior can be interpreted as the null hypothesis, so that the adjudicative authority can both incorrectly reject the null and sanction a complying subject (a type-I error) and incorrectly accept the null and exculpate an undeserving subject (type-II error). In the context of crime

deterrence, type-I errors amount to wrongful convictions of innocents. We model the relation between type-I and type-II errors below within a standard optimal deterrence framework. Finally, we discuss the empirical relevance of type-I errors.

Basic Setup

Let y_0 be the initial endowment equal for all agents and b the benefits from deviating from the prescribed behavior (e.g., committing crime). b is distributed among the agents with a generic distribution $z(b)$ and a cumulative $Z(b)$ with support $[0, \bar{b}]$. Let also h be the harm/externality generated by each individual's deviation (each individual takes this decision only once). For the sake of simplicity, all individuals are audited and brought in front of an adjudicative authority. The authority observes the amount of inculpatory evidence e that is produced against a defendant, and if this overcomes a certain threshold, $\tilde{e}$ then the authority imposes a monetary sanction s . For the sake of simplicity, we also assume that there is no welfare-improving deviation as in Becker seminal paper on crime (See also ▶ “Crime and Punishment (Becker 1968)” by Becker 1968 and also to “Becker, Gary S.”) (this would be a crime for which $b > h$) and that monetary sanctions are transferred from the defendant to society. Furthermore, in the function of social costs, we do not consider the private benefits from crime but only its social costs.

Therefore let e have a frequency distribution of $i(e)$ for the conforming defendant (innocent) and of $g(e)$ for the deviating defendant (guilty). Let $I(e)$ and $G(e)$ be the cumulative distributions of $i(e)$ and $g(e)$, respectively, and note that $I(\tilde{e})$ and $G(\tilde{e})$ are the probabilities of being acquitted for the complying and for the deviating defendant, respectively, given the evidence threshold $\tilde{e}$. To keep notation compact, we will often use I and G for $I(\tilde{e})$ and $G(\tilde{e})$, respectively.

The evidence is stochastically distributed, albeit in general more incriminating evidence is available against deviating defendants than against complying ones. First-order stochastic dominance is assumed $I(e) > G(e) \forall e \in]0, e_{\max}[$. Without

FOSD evidence would be produced randomly for the complying and the deviating alike, and therefore the whole criminal procedure would be pointless. Note also that G is the probability of type-II error and $1 - I$ is the probability of type-I error. Let us also define $\Delta(\tilde{e}) = I - G$ as the *accuracy* of the adjudicative procedure; Δ represents the ability of the procedure to distinguish complying from deviating defendants.

For our purpose, we assume the social planner optimizes deterrence only by affecting the threshold $\tilde{e}$ which in turn determines the error's trade-offs: for instance, an increase in $\tilde{e}$ generates both an increase in the number of wrongful acquittals G and a decrease in the number of wrongful convictions $1 - I$.

The risk-neutral individual does not deviate as long as the returns from deviating behavior are smaller than the expected returns of conforming. Since b varies across individuals, there exists a level of $\tilde{b}$ for which the individual is indifferent between conforming and not, and this determines the proportion of the population $Z(\tilde{b})$ who conforms.

Social welfare is thus $(1 - Z(\tilde{b}))h$: the social costs of harm caused by those defendants who deviate. On the other hand, the social planner only acts on the threshold $\tilde{e}$ which implicitly defines the trade-off between type-I and type-II errors. The link between the social planner's choice of the evidentiary standard $\tilde{e}$ which in turn determines the error's trade-off and the defendant's choice of conformity determined in $\tilde{b}$ are the ingredients to understand the role of adjudication in deterrence.

Let us begin by assuming agents to be risk-neutral utility maximizers. The returns from conforming are $E\pi_I = y_0 - (1 - I)s$, while the returns from deviating are $E\pi_G = y_0 + b - (1 - G)s$. All defendants for which $E\pi_I \geq E\pi_G$ will conform and therefore the threshold level of b which implicitly defines the conforming population is

$$\tilde{b}_m = (1 - (1 - I) - G)s \quad (1)$$

By looking at Eq. 1, we can single out the typical “deterrence effect” as $\tilde{b}$ increases both with the magnitude of the sanction ($\uparrow s \Rightarrow \uparrow \tilde{b}$)

and via an increase in the detection probability for the deviating defendants which in this model corresponds to a decrease in the probability of type-II errors ($\downarrow G \Rightarrow \uparrow \tilde{b}$). Furthermore, a “compliance effect” of type-I errors can be seen: $s \tilde{b}$ increases when the probability of being punished decreases for conforming defendants ($\uparrow I \Rightarrow \uparrow \tilde{b}$). Also a “screening effect” can be established: the higher is the accuracy Δ , the better the procedure can discriminate between conforming and non-conforming behaviors and the greater the advantages of staying conforming ($\uparrow \Delta \Rightarrow \uparrow \tilde{b}$). Finally, by simple inspection of Eq. 1, it is evident that marginal change in either $1 - I$ or G determines an equal decrease of $\tilde{b}$ as $\frac{\partial \tilde{b}}{\partial (1-I)} = \frac{\partial \tilde{b}}{\partial G} = s$. Under risk neutrality, type-I errors ($1 - I$) and type-II errors (G) have the same negative impact on the defendant’s incentive to comply. This is because on one hand type-II errors undermine compliance inasmuch as they decrease the probability of nonconforming defendants being finally sanctioned. On the other hand, type-I errors increase the opportunity costs of conforming relative to deviating.

Now that the threshold level $\tilde{b}$ is defined, the social welfare can be computed and derived with respect to the evidence threshold:

$$\begin{aligned} \frac{\partial SW}{\partial e} &= \partial(1 - Z(\tilde{b}_m))h \\ &= -z(\tilde{b}_m)(i(\tilde{e}) - g(\tilde{e}))sh \end{aligned} \quad (2)$$

Let $\tilde{e}_{\text{neutral}}$ be implicitly defined by $i(\tilde{e}) = g(\tilde{e})$. By inspection of Eq. 2, the optimal evidence threshold $\tilde{e}$ that minimizes social costs is $\tilde{e}_{\text{neutral}}$. In fact accuracy reaches its maximum level when the social planner chooses $\tilde{e}_{\text{neutral}}$ so that the distance between the two cumulative functions is maximized. If the social planner chooses a higher evidence threshold $\tilde{e}_{\text{pro-defendant}} > \tilde{e}_{\text{neutral}}$, then the error trade-off tilts in favor of the defendant as the probabilities of both correct and wrongful acquittals $-I$ and G , respectively, increase. $\tilde{e} > \tilde{e}_{\text{neutral}}$ necessarily also implies $g(\tilde{e}) > i(\tilde{e})$ by definition of the frequency distribution of $i(e)$ and $g(e)$. Notice that for levels of $\tilde{e} > \tilde{e}_{\text{neutral}}$, G grows faster than I and therefore accuracy cannot be maximal.

Evidence Thresholds, Standard of Evidence, and Error Ratios

While our analysis focuses on the evidentiary threshold $\tilde{e}$ that determines the probabilities of both type-I and type-II errors, there are other two common concepts that concern adjudication and that must be put in relation with our analysis.

The first one is the **standard of evidence**: it is generally understood as the level of certainty the adjudicative authority must reach in order to establish guilt in a criminal proceeding (or liability in civil one). Among the most common standards of proof used in different adjudicative procedures, there are the *preponderance of evidence* (*poe*) standard, the *clear and convincing evidence* (*cace*) standard, and the *beyond any reasonable doubt* (*bard*) standard. Although giving probabilistic interpretations of these standards of proof is very controversial (see Kaplow 2012, footnote 76 for a discussion), they are commonly understood to roughly coincide with the 50%, 75%, and 95% thresholds, respectively. Under *poe* (or *cace* or *bard*), the adjudicative authority must answer to the question of whether, given the evidence available, the likelihood that the defendant has deviated is larger than 50% (or 75% or 95% depending on the standard applied). These probabilities must be understood as Bayesian posterior probabilities of having deviated, and these are functions – following the Bayes’ rule – of the likelihood of the signal given by the densities i and g of the evidentiary threshold $\tilde{e}$ and on the prior probability of being brought in front of the adjudicative authority. The probability that a defendant has deviated or not also depends on the base rates of the two actions, $(1 - Z(\tilde{b}))$ and $Z(\tilde{b})$, respectively. The $\tilde{b}$ are determined endogenously by defendants’ decisions and ultimately depend on the evidence threshold $\tilde{e}$. Therefore in order to identify the proper threshold $\tilde{e}$ – in case the *poe* standard applies – one should ask what value of $\tilde{e}$ implicitly solves the equation $g(\tilde{e}) \cdot (1 - Z(\tilde{b})) = i(\tilde{e}) \cdot Z(\tilde{b})$. If the adjudicative authority needs to apply the *cace* or *bard* standard, one could simply multiply by either 3 or 19 the right side of the previous equation. As Lando

(2002) and Kaplow (2012) point out, the two notions – the one based on the optimal *evidence threshold* and the one based on the *standard of evidence* – are strikingly different. To begin with, the optimal evidence threshold is derived from welfare analysis and seeks to find the level of $\tilde{e}$ that maximizes social welfare. By contrast, within the *standard of evidence* framework, $\tilde{e}$ is derived by asking under what circumstances would the probability that the defendant before the adjudicative authority has actually deviated be 50% (or 75% or 95% or other conventional probabilities). In fact the optimal *evidence threshold* could be associated with any probabilistic *standard of evidence* whatsoever.

Another approach focuses on the **ratio of errors** and expresses the pro-defendant bias of adjudicative procedures in terms of error ratios. There seems to be something specific about type-I errors in the context of crime: scholars and rule makers across time and societies advocated a specific attention to the avoidance of type-I errors even at the expense of many type-II errors; arguably the most famous statement in this respect is the one of William Blackstone (1769) recommending that *it is better that ten guilty persons escape than that one innocent suffer*. Dekay (1996) systematizes the relation between the standards of evidence and the error ratios. We can interpret these as ratios of errors' frequencies where the frequency of erroneous acquittals is the conditional probability that a truly deviating defendant is acquitted (type-II error) multiplied by the base rate of the action $(1 - Z(\tilde{b}))$, while the frequency of erroneous conviction is the conditional probability that a truly complying defendant is convicted (type-I) multiplied by the base rate $Z(\tilde{b})$. So the type-I error ratio (sometimes also called the Blackstone's error ratio) is defined as $\frac{G \cdot (1 - Z(\tilde{b}))}{(1 - I) \cdot Z(\tilde{b})}$.

All else being equal, higher standards of evidence that affect the trade-off between G and I do imply higher Blackstone-like error ratios. However, it should be noticed that the optimal *evidence threshold* could be associated with many different error ratios depending on the base rates.

Risk and Loss Aversion

Subjects are known to be generally risk-averse in their utility of income. We thus introduce risk aversion in the measure of the monetary gains from crime b following Rizzolli and Stanca (2012). If b are monetary gains for which utility $U(\cdot)$ can be derived, then the expected utility of complying is $IU(y_0) + (1 - I) \cdot U(y_0 - s)$, while the expected utility of deviating is $GU(y_0 + b) + (1 - G) \cdot U(y_0 + b - s)$. The threshold level of $\tilde{b}_{eu}$ that triggers a defendant to deviate is implicitly defined by

$$\begin{aligned} & I[U(y_0) - U(y_0 - s)] \\ & - G[U(y_0 + b) - U(y_0 + b - s)] \quad (3) \\ & \geq U(y_0 + b - s) - U(y_0 - s) \end{aligned}$$

Equation 3 shows that when there is an increase in either of the errors (increase in G or decrease in I) on the left-hand side of the equation, defendants find deviation convenient for lower levels of b (on the right-hand side). However, given the concavity of the utility function, the negative impact of type-I errors $(1 - I)$ on the threshold level $\tilde{b}_{eu}$ and thus on social welfare is stronger than that of type-II errors (G). To see why, note that $U(y_0) - U(y_0 - s) > U(y_0 + b) - U(y_0 + b - s)$. In order to maintain the same level of deterrence, a given percentage increase of $1 - I$ must be compensated by a smaller percentage decrease of G . Therefore, assuming risk aversion, type-I errors $(1 - I)$ create more disutility and thus induce more deviation than comparable type-II errors (G); therefore, social costs are minimized for a $\tilde{e}^* > \tilde{e}_{neutral}$. The opposite result holds if we instead assume risk-seeking behavior.

Another interesting extension concerns the introduction of loss aversion: a departure from the expected utility framework that has been incorporated in models such as the cumulative prospect theory (Dhami and al Nowaihi 2013). These models build on the empirical observation that people tend to think of possible outcomes of a choice under uncertainty relative to a certain reference point and tend to prefer the avoidance of losses (outcomes below the reference point) than the acquisition of comparable gains (outcomes above the reference point). Incorporating

reference-dependent preferences and loss aversion in the model is not trivial (see Nicita and Rizzolli 2014); however, the intuition and the results are quite simple: type-I errors always imply a potential loss relative to the status quo, while this is not necessarily true for type-II errors. To conclude, in presence of loss aversion, type-I errors ($1 - I$) represent a net loss and impact the defendant value function more than comparable type-II errors (G); therefore, social costs are minimized for a $\tilde{e}^* > \tilde{e}_{\text{neutral}}$.

Cost of Sanctions

So far we have assumed that the sanction s is monetary and that it implies – once imposed – a costless transfer from the defendant to the society. However, the imposition of sanctions implies both private costs of punishment to defendants and to society as well. Nonmonetary sanctions are a social cost (Shavell 1987) as their imposition implies a disutility for the defendant that is not transferred to society. Furthermore, all sanctions – including monetary fines – must be administered and therefore imply a social cost (Polinsky and Shavell 1992).

Define c as the total cost (both to the defendant and to the society) of imposing a sanction. The social welfare function (assuming risk neutrality) should be rewritten as the following:

$$SW = [1 - Z(\tilde{b})]h + [1 - Z(\tilde{b})](1 - G)c + Z(\tilde{b})(1 - I)c \quad (4)$$

The first term of Eq. 4 represents the harm/externality of deviating, as before. The second term represents the expected total costs of imposing sanctions on deviating defendants, and the third term represents the expected total costs of punishing complying defendant (type-I errors). The problem lies in defining the optimal $\tilde{e}$ that minimizes the expected total costs from crime, including the costs of punishment. As before, the first term is minimized for $\tilde{e} = \tilde{e}_{\text{neutral}}$. However, the second and third terms are minimized for $\tilde{e} \rightarrow \infty$. In fact for an evidence threshold $\tilde{e}$

arbitrarily high, the probability of correctly imposing a sanction on a deviating defendant ($1 - G$) or erroneously imposing a sanction on a complying defendant ($1 - I$) decreases to zero and – since nobody is punished – there are no costs of punishment for society. When social costs are considered, the costs of harm implied by the first term must thus be balanced against the costs of punishment of the second and third term. Therefore, in the presence of costs of punishment, the social costs of harm must be weighted against the social costs of punishment, and therefore social costs are minimized for $\tilde{e}^* > \tilde{e}_{\text{neutral}}$. This result is based on Rizzolli and Saraceno (2013).

Identity Errors

Lando (2006) introduced a distinction between *mistakes of act* and *mistakes of identity*. *Mistakes of act* happen when a defendant is judged deviating when in fact he was complying. These are adjudicative errors we have been focusing on so far, for which the main concern of the adjudicative authority is whether there actually was any deviation at all. Note that, in case of mistakes of act, the two errors are independent: an increase in wrongful convictions does not imply any change in the number of wrongful acquittals. Then there are *mistakes of identity*, by which in the presence of deviations that can be easily observed, such as a murder or a robbery in the context of crime, the wrong person can be incriminated for an act that actually did happen. These are the cases where the occurrence of the deviation cannot be denied and the authority is concerned with who committed the crime. Note that in this case the two errors for a given crime are linked, as the conviction of an innocent person implies the acquittal of the person actually responsible for it.

Suppose that at time t_1 there exists an exogenous probability $\beta_{i,g}$ that a defendant is sanctioned for a deviation that has already happened at t_0 and which the subject is not responsible for (a mistake of identity). This exogenous probability can vary depending on the decision of the defendant at t_1 : it seems reasonable to assume that abstaining from a crime at t_1 reduces the

probability of a mistake of identity, so that $\beta_i \leq \beta_g$. Thus the returns from conforming at t_1 are $E\pi_I = y_0 - (1 - I)s - \beta_i s$, while the returns from deviating are $E\pi_G = y_0 + b - (1 - G)s - \beta_g s$. The threshold level of b which implicitly defines the conforming population is

$$\tilde{b}_{\text{identity}} = (1 - (1 - I) - G)s - (\beta_i - \beta_g)s \quad (5)$$

Inspection of Eq. 5 and comparison with Eq. 1 highlight the role of mistakes of identity vis-à-vis deterrence implicitly defined by $\tilde{b}_{\text{identity}}$. The first part is equal to Eq. 1, while in the second part, if $\beta_i = \beta_g$ as Lando (2006) hypothesized, then identity errors occurred at t_0 have no impact on deterrence at t_1 . However, if $\beta_i < \beta_g$, then identity errors actually have a positive impact on deterrence. The reason is intuitive: the decision to deviate in t_1 triggers a net increase in the probability of being wrongfully convicted because of a mistake of identity. Of course this result is based on the assumption that the probability of identity errors in t_1 is determined exogenously, and it is not a function of $\tilde{e}$. Furthermore, identity errors impose a necessarily constraint between the input of wrongful acquittals and the output of wrongful identity convictions; Garoupa and Rizzolli (2013) show that once this constraint is considered, mistakes of identity have a net negative impact on deterrence.

Errors and the Precaution of Harm

Another main area where the role of adjudicative errors has been explored is tort law (see Png 1986; Lando and Mungan 2017, among others). The standard model of tort law substitutes the dichotomous choice between complying and deviating with a continuous choice about the level of activity/care. We will discuss the main implications below. However, some novel conclusions can be drawn also from applying the dichotomous choice model. In this framework, the defendant chooses between *conforming* to the prescribed standard of care or *deviating* and not taking any precaution. Since taking precautions is costly, we can interpret b as the opportunity cost of conforming (by deviating, the defendant saves

b). Furthermore, the sanction is equal to the harm inflicted since the goal of the tort system is compensation, and the decision to conform only reduces the expected harm: when conforming, harm h_i is produced with probability α_i , while when deviating, harm h_g is produced with probability α_g , where $h_g > h_i$ and $\alpha_g > \alpha_i$. Adjudicative errors can occur in the usual way, and therefore, a risk-neutral defendant's returns from conforming are $E\pi_I = y_0 - (1 - I)\alpha_i h_i$, while the returns from deviating are $E\pi_G = y_0 + b - (1 - G)\alpha_g h_g$. All defendants for which $E\pi_i \geq E\pi_g$ will conform and therefore the threshold level of b which implicitly defines the conforming population is

$$\tilde{b}_{\text{care}} = (1 - G) \cdot \alpha_g h_g - (1 - I) \cdot \alpha_i h_i \quad (6)$$

By comparing Eq. 6 with Eq. 1, one immediately realizes that type-I errors have a smaller impact on the incentive to comply than type-II errors as $\frac{\partial b}{\partial(1-I)} = \alpha_i h_i < \frac{\partial b}{\partial G} = \alpha_g h_g$; this is because complying causes a smaller expected harm. Also social welfare changes as now also complying defendant causes harm. To find out the optimal $\tilde{e}$, we compute $\frac{\partial SW}{\partial e} = 0$ and thus

$$\partial Z(\tilde{b})\alpha_i h_i + \partial(1 - Z(\tilde{b}))\alpha_g h_g = (\alpha_i h_i i(\tilde{e}) - \alpha_g h_g g(\tilde{e}))(\alpha_i h_i - \alpha_g h_g) = 0 \quad (7)$$

Rearranging Eq. 7, we have that $i(\tilde{e}) = \frac{\alpha_g h_g}{\alpha_i h_i} g(\tilde{e})$, and since $\frac{\alpha_g h_g}{\alpha_i h_i} > 1$, the equality can be satisfied only for $\tilde{e}^* < \tilde{e}_{\text{neutral}}$. We can thus conclude that when defendants face a dichotomous choice between complying and causing a smaller expected harm and deviating and causing a larger expected harm, type-I errors impact deterrence less than type-II errors, and therefore welfare is maximized for a level of evidentiary standard smaller than the neutral one.

Precautionary Activities and Chilling of Desirable Behavior

In both the crime and the tort contexts, the choice of deviating causes social harm at least in

expected terms. Compliance causes no harm in the crime context, while it produces a smaller social harm in the tort context. In many situations, however, defendant compliance can have both harmful consequences and benign ones. One may think of the case of competition policy, where the threat of antitrust sanctions may discourage efficient, pro-competitive behavior; another case may be medical malpractice, where worries about false positives may prevent cost-effective care. Kaplow's (2011) model envisages a population that can engage in a harmful act that produces a private benefit as well as a negative externality and another population that can only engage in a benign act that produces no externality. The two types of act are initially indistinguishable to the authority, but the adjudicative procedure gives rise to an evidence signal e that is higher for harmful acts than for benign ones. As before, the authority sanctions subjects whose acts produce an evidence signal higher than a certain cutoff value $\tilde{e}$. However, now the expected sanction raises both the costs of the harmful act and that of the benign one, thus chilling desirable behavior. Kaplow (2011) shows that the optimal $\tilde{e}$ that equates the (falling) marginal benefits of deterring harmful acts with the (rising) marginal costs of chilling benign acts is such that $\tilde{e}^* > \tilde{e}_{\text{neutral}}$. Intuitively it is generally optimal to raise the sanction and simultaneously raise $\tilde{e}$, holding deterrence constant. In fact the only consequence of this policy is a reduction in chilling costs.

A similar model is proposed by Mungan (2011) where subjects can choose between *inaction* (precautionary activity) and *action*, and this second choice can produce *no externality* (desirable behavior) or a *negative externality* (harmful activity). The authority cannot distinguish with certainty whether the activity is harmful or benign but must rely on an evidence signal e and balance the usual errors' trade-off. The expectation of sanctions wrongfully imposed on desirable behavior induces subjects at the margin to switch over to precautionary activities. Again, Mungan (2011) shows that the optimal evidence threshold is such that $\tilde{e}^* > \tilde{e}_{\text{neutral}}$.

Judicial Errors When the Choice of Care Is Continuous

In the model presented so far, the defendant's choice between complying and deviating is dichotomous. However, other situations like torts are best described by a continuous choice of care level x . In the prevailing model of tort, a legal standard $\bar{x}$ is set in order to determine liability by a potential injurer: the defendant avoids liability if his level of care is equal or above the standard one which is usually equated to the optimal level x^* . Craswell and Calfee (1986) introduce legal errors in this context by proposing a model where such legal standard is uncertain in the sense that defendants who choose a level of care x only know that there is a probability $F(x)$ (decreasing in x) that they will be sanctioned so that choosing higher levels of x decreases the probability to be punished. So if they choose $\underline{x} < x^*$, there is a $1 - F(\underline{x})$ probability of type-II error (the defendant is not made liable even if he took less than the efficient level of care), while if they choose $\bar{x} > x^*$, there is a $F(\bar{x})$ probability of type-I error (the defendant is made liable even if he took enough care). Assuming that also both the sanction s and the opportunity cost of care b are increasing functions of x , Craswell and Calfee (1986) show that with respect to the socially optimal level of x , the defendant's choice of x can be either undercomplying (the defendant chooses $\underline{x} < x^*$) or overcomplying ($\bar{x} > x^*$). This is because, on one hand, there is always a positive chance $1 - F(x)$ of acquittal, and this increases the returns of taking lower levels of care. But on the other hand, the expected sanction depends on the probability $F(x)$, and this can be driven down by increasing the level of care. The relative impact of these two countervailing effects on the final level of x can be of either sign as it depends on various features of the legal environment and in particular on the amount of uncertainty. Craswell and Calfee (1986) show that under some plausible assumptions concerning the distribution of errors, defendants will usually take an excessive level of care. In other words, while the possibility of escaping liability when the defendant has not taken enough precaution (type-II error) has the usual adverse

effect on the incentives to take precaution, the possibility of being wrongfully held liable even when one has taken enough precautions (type-I error) induces the defendant to increase the level of precautions (under some plausible conditions).

Further Effects on Evidentiary Standards and on Type-I Errors

In addition to the literature survey above, many authors have also explained the high evidence threshold usually observed in legal trials using deterrence-based arguments that point at (i) biased evidence selection (Schrag and Scotchmer 1994), (ii) parties' evidence production expenditure (Yilankaya 2002), (iii) optimal exercise of care by parties (Demougin and Fluet 2006), (iv) marginal deterrence (Ognedal 2005), (v) repeated offenders (Chu et al. 2000), and (vi) emotional costs of indignation (Nicita and Rizzolli 2014).

Furthermore, without making reference to a specific utilitarian approach based on the deterrence rationale, a consistent number of papers simply postulate that wrongful convictions of innocents are morally repugnant and thus inherently worse than type-II errors. Arguments that justify this position are reviewed in Epps (2015). These arguments are mainly deontological and transcend the utilitarian framework (See also ► [“Retributivism”](#)) although they can still be considered in our model by overweighting the impact of type-I errors on the social welfare function along the lines of Miceli (2009).

Empirical Relevance

The role of type-II errors has been greatly analyzed empirically and experimentally; there exists a vast literature testing Becker's deterrence hypothesis with real data on incarceration and on the death penalty (Chalfin and McCrary 2017). There is also a small stream of literature testing the deterrence hypothesis in the lab (see literature cited in Khadjavi 2015); (See also ► [“Experimental Law and Economics”](#)).

Most of this literature, however, ignores type-I errors and their impact on deterrence and behavior. This asymmetry is easy to understand once one considers that type-II errors (crimes that go unpunished) are far more easy to be observed and measured than type-I errors (wrongful convictions can in fact be mistaken for correct convictions). Empirical research on type-I errors has only recently taken off either comparing agreement rates of judges and juries (Gould et al. 2014) or by using DNA testing introduced in the 1990s. Many innocent defendants used DNA testing to clear themselves after conviction whenever biological evidence from the crime scene had been retained. By adopting this strategy, Risinger (2007) estimated the type-I error rate in capital rape-murder cases to be between 3.3% and 5% in 1982–1989. Gross and O'Brien (2008), using post-1973 US data on death sentences (See also ► [“Death Penalty”](#)), estimated a type-I error frequency of wrongful death sentences to be at least 2.3%. Most of this literature is concerned with measuring the magnitude of type-I errors and less with the assessment of the impact of type-I errors on general deterrence (Gould et al. 2014). A small number of controlled lab experiments try to assess the impact of type-I errors on deterrence: Grechenig et al. (2010) first showed that both errors greatly undermine deterrence in a voluntary contribution mechanism (VCM) type of game. Rizzolli and Stanca (2012) disentangled the effects of each type of error and found that type-I errors are more detrimental to deterrence than type-II errors. Marchegiani et al. (2016) found the same effect within a principal-agent setting, while Markussen et al. (2016) using a VCM design found instead the opposite effect: that type-I errors are less detrimental than type-II errors.

Definition

Incommensurability is a failure, or impossibility, to make value comparisons of different choices. It represents an important criticism of the proportionality test in judicial decision-making and of the cost-benefit analysis as a tool for assessing public policy. This entry summarizes the basic theories of value incommensurability.

Motivation and Delineation

Incommensurability is a failure, or impossibility, to make value comparisons. Its consequence is that choices among incommensurable options cannot be led by reason, i.e., cannot be rational. A few examples may help to illustrate such choices: upon arrival at Auschwitz, Sophie is forced to choose which one of her two children would be gassed and which would proceed to the labor camp; an individual needs to choose

whether to pursue a career as farmer or as a violinist; one wonders, whether Mozart is a better composer than Michelangelo was sculptor; a city needs to find a trade-off between air quality and heating during winter time.

Conceptually, it is useful to distinguish two types of incommensurability, positive and normative. Positive incommensurability obtains when a value comparison is objectively (technically) impossible, as is arguably the case for Sophie. It would be difficult to argue that her choice to save the son and sacrifice the daughter was arrived at by comparing the two and finding that her son's life had more value to her than the life of her daughter. In fact, the choice itself is a tragedy here; quite apart of the tragic outcome leading to the death of one of her children. This is why Sophie never recovers from that experience and eventually commits suicide. Normative incommensurability is the claim that some things ought not to be compared, since doing so would lead to undesirable consequences. One may say, for instance, that trying to express air quality in terms of money would lead to its "commodification" and demeaning.

At the individual level, people constantly make choices between alternative courses of action whose values are difficult, or even impossible, to ascertain objectively. Should "I get the green shirt or blue pants? Or, should I invite friends over for dinner instead?" "Should I buy more children's books or a child seat?" "Should I cross the road right here, saving myself 15 s of walk, or go to the

zebra, lowering the chance of being run over?" And so on.

Economists have long been aware of issues pertaining to objective valuation and particularly cautious when it comes to the possibility of interpersonal comparisons. They usually assume that individuals' choices follow from innate preferences (see Stigler and Becker 1977). Preferences enable individuals to determine the relative value of alternative courses of action to *them*, guiding their choices. And, as long as those choices do not affect others, or do so to a negligible extent, they are best left to those very individuals to be made. In this line of thinking, incommensurability is indistinguishable from indifference, except for extreme dilemmas, such as Sophie's, or curiosities, such as choosing between Mozart and Michelangelo. In fact, economists avoid the problem of incommensurability altogether by assuming it away, that is by assuming that preferences are rational, i.e., complete and transitive (see Mas-Colell et al. 1995, chap. 1). Individual rationality, i.e., the ability to make reasonable choices in accordance with one's individual preferences, is also a default assumption underlying much of private law (Lucy 2007, chap. 3; Voyiakis 2017, chap. III.C).

However, issues arise when individuals' choices have significant external effects onto others, as is commonly the case. In such cases, the society must somehow determine what are the appropriate courses of action (Coase 1960). In other words, it must be determined what *we* should do. Are people allowed to wear green shirts that are out of fashion? Are people allowed to wear hijabs in public schools? In such cases, interpersonal comparisons, even if implicit, are inevitable.

At the societal level, such *we*-type decisions are frequently made through two types institutions: political (parliaments, executive) and judicial. While incommensurability issues pertain various types of decision-makers and contexts, judges are in a specific position because (a) they inevitably make decisions that favor one party (broadly defined) at the expense of another, (b) they do so on behalf of the society, and (c) they do so as an unelected bureaucratic entity,

i.e., without democratic legitimacy. In effect, judges are tasked to make choices for the society, the *we*-type choices, similarly as individuals make choices for themselves, the *I*-type choices. This is when the incommensurability issues loom large.

When the standard, legalistic, approaches fail, that is when the law does not state clear "social preferences," courts opt for the proportionality test (see the entry "[► Proportionality Test](#)" in this encyclopedia for more details). This legal method allows them to decide hard cases, i.e., cases where two or more legitimate rights collide and a decision necessarily leads to one right prevailing at the expense of another. In order to decide such cases correctly, the court balance the satisfaction of some rights and the damage to other rights resulting from a judgement. The proportionality test can be viewed as a method through which the courts uncover the social preference and that forces them to do so transparently.

This enterprise seems to be, however, dubious if the colliding rights are incommensurable. The intuition was put vividly by Antonin Scalia who characterized the balancing approach as something "more like judging whether a particular line is longer than a particular rock is heavy" (Bendix Autolite Corp. v. Midwesco Enterprises 1988). Incommensurability is also presented as an objection to the cost-benefit analysis, which assumes that any available options can be valued along a common scale whose units are typically money (Frank 2008; Sunstein 1994).

Positive Incommensurability

Failure of Transitivity

Two options are commensurable if one of them is better than the other or if their value is the same. Two options are incommensurable if none of the three value relations hold. For instance, if it is neither true that an option A is better than an option B nor that B is better than A, and yet it is not the case that they are of the same value. Take the example of Mozart and Michelangelo. Arguably, neither was more creative than the other nor were their creativities the same. One can

then conclude that their creative qualities are incommensurable.

Incommensurability is the failure of transitivity, which can be shown by the Small-improvement Argument (Raz 1986, chap. 13, p. 325). Suppose we are comparing Mozart and Michelangelo and agree that neither is better than the other. Can we say that they are of the same quality? Think of a hypothetical Mozart that is in some dimension slightly better than the actual one and is the same in all other respects. Clearly, this “Mozart⁺” is better than the original Mozart. However, if it is still the case that Mozart⁺ isn’t better than Michelangelo, then Mozart and Michelangelo are incommensurable.

Implications for Rational Choice

At least at first glance, incommensurability seems to provide disturbing prospects, because it “can leave us paralysed, not knowing what to choose” (Waldron 1994, p. 815). True dilemma means that there is no objective value basis to say about one decision rather than the other that it is the right answer.

From the point of view of practical rationality, we can distinguish three normative statuses of action: rationally demanded, rationally prohibited, and rationally permitted. If incomparability embodies the third status, then it renders both alternatives for choice rationally permissible, that is, there is sufficient reason to choose either alternative. Therefore, from the point of view of the rationality requirement, the choice of any of the two alternatives is faultless and blameless (Raz 1999, chap. 2).

Parity

Chang (2002) argues that failure of transitivity does not always imply incommensurability. Building up on the Small-improvement Argument, she develops the Unidimensional Chaining Argument to show this. Returning to our example with Michelangelo and Mozart, think of a very poor sculptor, she names him Talentlessi. Clearly, Talentlessi will be a worse sculptor than Michelangelo and arguably less creative than Mozart. Now think of adding units of talent to him. Talentlessi⁺ will be better than Talentlessi but still worse than both Mozart and

Michelangelo. The same will probably be the case for Talentlessi⁺⁺, and so on. However, as Talentlessi becomes more and more talented, his qualities will be approaching those of Michelangelo. At some point, we will have Talentlessi^{*} who is exactly like Michelangelo.

Because Talentlessi^{*} as well as Michelangelo are comparable with all the lesser Talentlessis and because those are comparable with Mozart, Michelangelo and Mozart are comparable too.

This argument relies on the Small Unidimensional Difference Principle stating that a small unidimensional difference cannot trigger incomparability where before there was comparability. Thus, if Talentlessi is comparable to both Michelangelo and Mozart, so must be Talentlessi⁺, Talentlessi⁺⁺, and eventually Talentlessi^{*}.

Chang (2002) argues that in situations of transitivity failure, i.e., none of the three value relations hold, but when the objects are comparable, a fourth relation obtains: *parity*. Because Mozart and Michelangelo are comparable and yet neither is superior nor are they the same, one may say that they are on par.

Normative Incommensurability and Commodification

Certain transactions give rise to moral opposition and some are even illegal. Some contemporary authors criticize the exchange of money for health care, human organs, personal privacy, human dignity, voting rights, pollution rights, public education, surrogacy and sexual services, works of art, and so on (see Sunstein 1994). These value-bearers, due to their special moral, sacred, cultural, or generally symbolic significance, are supposed to be inherently incompatible with market exchanges and qualified as incommensurable (or incomparable) to money.

Commodification is usually understood as an assignment of price to something not previously considered in economic terms. This may then transforms goods, relationships, services, ideas, and also people’s lives into objects of trade. Here, incommensurability is not the failure of

value comparison. Rather, the argument here is that even if those values are in principle comparable, doing so has negative consequences, particularly in the sense of demeaning their true value.

In order to understand the phenomenon of normative incommensurability, one needs to think about it in the broader social and cultural context. Interpersonal transactions have no universal nature; their moral and symbolical significance is dependent on social conventions of relevant community (Cohen 2003). When people strictly adhere to certain principles or stubbornly reject some trade-offs, it does not have to mean that they are irrational. Perhaps they signal that they are loyal to certain values that their community recognizes as significant. At the same time, they build, intentionally or not, a reputation as good people who can be reliable partners in different collaborative projects (Posner 1998, 2000, p. 193).

One example of criticized commodification concerns the tort law. Radin (1993) criticizes the conception of harm compensation because it conceives the harm to the injured victim as commensurable with money. The market approach takes the bodily harm in the same way as any economic cost and she rejects it as a form of inappropriate reductionism. The market idea that each person's attributes have a monetary equivalent is incompatible with an ideal of individual uniqueness (Radin 1987). If bodily injury and money aren't commensurable to each other, then no payment of money can restore persons to the status quo ante. This means that the corrective justice, as a fundamental ethical principle of the tort law, must demand something other than rectification. Radin (1993) proposes a noncommodified conception of compensation, which requires a payment as a way both to bring the wrongdoer to recognize that he has done wrong and to show the victim that her rights are taken seriously.

Another example is the social institution of friendship. Perhaps we can hire someone to behave like our friend but it will not be a real friendship. It appears that commodification is detrimental to the very nature of some values by imposing a substitution regime on them (Sandel 2012, 2013). Friendship can't be for sale without

losing its own nature. If we were to offer someone a financial compensation for giving up his friend, he would probably have rejected such an offer as an insult. This is different than when someone is offended by getting an inappropriately low financial offer for something that is normally for sale. At the same time, it does not mean that friendship is more valuable than any amount of money. The main explanatory reason of the different approach is rather the fact that we understand friendship and business as two mutually independent social institutions that fulfill very different purposes (Regan 1989; Sunstein 1994, see also Khalil and Marciano 2018).

A third example is blood donation. Selling blood is something different from a free donation, where blood is symbolically valued as the gift of life itself (Anderson 1990). Of course, sold blood can save human lives as well. But we may need to take account of nonmarket norms that people recognize as morally significant. Titmuss (1971) argued that the commodification of blood erodes the people's sense of moral duty and therefore their willingness for free donation is significantly weakened. As a result, the number of voluntary donors is declining and they are replaced by poor people who sell their blood as a way of making money. This fact can also have a harmful effect on the quantity and quality of available blood (Titmuss 1971).

Summary

Positive value incommensurability presents a challenge for rational decision-making, particularly by public authorities and courts. A way out is to say that any action (inaction) is rationally permissible as neither decision is better or worse than the other. Normative incommensurability, on the other hand, typically seems to serve as an argument *for* a particular action or inaction. A full-fledged discussion of various nuances of the incommensurability literature and the criticisms is beyond the scope of this entry. In order to learn more about the phenomenon, its criticisms, and implications, we refer the reader to the readings below.

Vertical Integration

Giuseppina Gianfreda
University of Tuscia, Viterbo, Italy

Abstract

Economists have long been inquiring into the determinants of vertical integration. Theories which explain the rationale for firms' decision to expand vertically also predict different implications in terms of welfare. A body of literature traces vertical integration to the problem of the origin and the boundary of a firm and explains integration on the bases of the economization of costs related to market transactions and contract incompleteness; this literature dates back to Coase's (*Economica* 4:386–405, 1937) seminal article on the nature of the firm and has been developed within the Transaction Costs Economics framework and subsequently under the Property Right approach. Another set of contributions studies vertical integration with respect to firms' competitive environment. In this context, two main views emerge: on the one hand vertical integration has been considered as a way to exploit market power and implement (otherwise banned) price or exclusionary strategies and may thus raise antitrust concerns; on the other hand, integrating firms can cope with negative "vertical" externalities and increase efficiency. Another set of contributions, often referred to

as vertical equilibrium or dynamic models, explains vertical integration with respect to the degree of market maturity, as the Stigler model, or to demand fluctuations. Other models explain the incentive for vertical integration by factors related to uncertainty, i.e., over the supply of the input good or in the demand of the final good.

Introduction

Vertical integration refers to the organization of successive stages of production or distribution – i.e., a supplier and a retailer – within a single firm. Two aspects are relevant in the definition of vertical integration: (i) the ownership or control by the same firm over the successive stages of production or distribution process and (ii) the substitution of external with internal exchanges.

Vertical integration can be *full* or *partial*. Under the first aspect, i.e., ownership or control, integration is full (partial) if the firm acquires all (part of) the shares in a vertically related firm. Under the second aspect, i.e., the internalization of exchanges, full vertical integration means that the entire output of an upstream unit is employed in a downstream unit or the entire quantity of an intermediate input in the downstream unit is obtained from the upstream process, while partial integration means that most of the output of the upstream unit is employed as most of the input in the downstream unit, that is to say that the stages of production are not internally self-sufficient.

Vertical integration can result from a process of *internal* growth or may be due to *external* expansion, i.e., the merging of a firm with another firm operating in a successive stage of production or distribution. Integration can take place in two direction, i.e., *upward* and *forward*; in the first case, a firm expands to get control over an upstream firm, for example a manufacturer who acquires an input supplier, while in the second case the control is on a downstream firm, for example a manufacturer who acquires a retailer.

Transaction Costs and Contract Incompleteness

Transaction Costs Economics

Under Transaction Costs Economics (TCE), different governance structures, i.e., internal organization versus market transactions, are evaluated with respect to the comparative costs of ensuring task completion.

TCE dates back to the pioneering article of Ronald Coase “The Nature of the Firm” in 1937 and has been enriched with further important contributions since the 1970s as the concept of transaction costs has been widened.

Coase’s starting point is that the distinguished mark of the firm is the suppression of the price mechanism; within a firm market transactions are eliminated and the allocation of resources is dependent on the entrepreneur-coordinator who directs production. The reason is that using the price mechanism has costs, which would be reduced or avoided by internalizing production. Coase focuses one type of costs in particular, i.e., long-term contracts, such as labor. Whenever a long-term contract for the supply of a service is preferred to several short period contracts – because in such a way some costs which are incurred in making each contract are avoided or because of the parties’ risk attitudes – the purchaser would not want to specify all details that the supplier is expected to do owing to uncertainty and difficulty of forecasting; in other words, he will not know which course of action he will want the supplier to take. The contract will then state only the limits of the supplier action and the direction of resources will depend on the buyer. Coase defines the firm as a system of relationship which emerges when the direction of resources rests on the entrepreneur.

As firms emerge because they allow to save market transaction costs, they will expand until the cost of organizing an extra transaction within the firm will equal the costs of carrying out that transaction in the market or the cost of organizing it in another firm. Firm size is then limited by the decreasing returns to the entrepreneur function, by the difficulty in allocating inputs in the uses they value most as the internalized transactions

increase, and by the increase in the input price due to the advantage of smaller firms.

If Coase explains the nature of the firm on the basis of the comparative transaction costs differences, Williamson (1971, 1975, 1985) develops further the concept of transaction specifying where those differences reside. His approach rests on two behavioral assumptions which break with the orthodox view of the maximizing man, i.e., the concept of bounded rationality and that of opportunistic behavior. The concept of bounded rationality was introduced by Herbert Simon (1955) who questioned the assumption of the “economic man” as being capable of making absolutely rational decisions; the capacity to acquire the relevant information for decision taking is limited, and so is the skill to compute and calculate among the different alternatives the course of action which leads to optimization.

In the presence of bounded rationality, economic agents can disclose misleading and distorting information in an opportunistic way; as a result, the assumption of self-interest seeking individual broadens as to encompass deceit. Under these circumstances, the neoclassical frictionless transaction paradigm may not always apply, in particular when bilateral interdependence between traders intrudes conflicts may arise which impair task completion. Alternative governance structures have then to be evaluated with respect to the comparative costs of ensuing – i.e., planning, adapting, and monitoring – task completion.

Williamson pinpoints three dimensions of transactions which are critical for TC evaluation: (i) asset specificity, (ii) frequency of transactions, and (iii) uncertainty. Asset specificity is the crucial condition for TC; it refers to the degree to which an asset can be reused in alternative ways and by alternative users without any loss of productive value. When investments are asset specific, their cost opportunity is much lower than they would be in the best alternative use or for an alternative user should the transaction not be completed; hence, the identity of the parties involved in the transaction becomes relevant as well as the continuity of the relationship. Asset specificity gives rise to bilateral interdependence.

Moreover, as the supply relation has to be adapted through time in response to disturbances, in evaluating the comparative advantage of internal organization versus market transactions, the ease of effecting intertemporal adaptations must be taken into account. On the one hand, market transactions allow production cost control more efficiently; on the other hand, in presence of asset specificity, they impede ease of adaptation. Vertical integration has the advantage of allowing the harmonization of interest, thus facilitating the sequential adaptive decision-making process.

Klein et al. (1978) focus on the possibility to appropriate quasi-rents from specialized asset – defined as the excess of asset's value over the value it would have in its next best use – by an opportunistic contractor as a reason for vertical integration. They refer in particular to the post contractual opportunistic behavior which will emerge once a specific investment is made no matter the enforceability of the contract. Even if a contract could unambiguously specify all relevant dimensions the threat of production delays should a litigation initiate may be an effective bargaining device.

Property Right Approach

Hart and Grossman (1986) observe that if TC approach helps understand integration when the costs of contracting between independent firms are higher, it fails to explain the limits to integration – if the right conditions are set and the owner of one of the firms becomes the employee of the other firm, any two independent owners can be better off integrating. Hart and Grossman thus sharpen Williamson TC-based arguments and define integration in terms of ownership of assets. Here again the problem rests in the difficulty in writing a contract which provides for all the payments and actions under every observable state of nature. Whenever it is costly for a party to write a contract which specifies the list of rights it desires over a list of another party's assets, it may be optimal for the first party to purchase all rights except those specifically mentioned in the contract; vertical integration is then the acquisition of the residual right of control over a supplier or a purchaser.

In this framework the costs of integration stem from the symmetry of control, i.e., when residual rights are purchased by one party, they are lost by the other. Symmetry of control creates distortions because of contractual incompleteness. One problem arises because the allocation of ownership rights changes the returns of the investment and by this way the level of investment. A controlling firm can use its residual right of control to increase the share of ex post surplus, and this induces the controlled firm to underinvest; as a result integration is optimal only if one firm decision is particularly relevant as compared to another.

Hart and Moore (1990) further specify the model by interpreting ownership right over an asset as the ability to exclude others from the use of this asset. Assuming asset-specific or person-specific productivity acquisition and incomplete contracts, the model predicts how changes in ownership affect employees and manager incentives; integration is then efficient – holdup is reduced – whenever the acquiring firm investment is important or the acquiring firm is an important trading partner or in the presence of asset complementarity.

Vertical Integration and the Competitive Environment

The rationale for vertical integration has been widely debated in the literature with respect to markets' competitive structure. On the one hand, integration can be seen as a way to achieve foreclosure or replicate otherwise banned price strategies such as price squeeze; from this perspective vertical integration may be a matter of concern for antitrust authorities. On the other hand, vertical integration can be explained as a response to “vertical externalities” (Tirole 1988); integrating firms may cope with efficiency losses due to variable proportions, double marginalization, and free riding problems, or, in the monopsony case, input rents extraction.

At the heart of those theories is the neoclassical firm assumption. In this setting integration is seen as an alternative to vertical agreements such as exclusive dealings, franchising, royalties, resale

price agreements, or other price strategies. Vertical integration is then at the extreme end of the spectrum; theories on the pros and cons of vertical integration from the standpoint of competition usually apply to vertical restraints.

Integration, Foreclosure, and Price Discrimination

Hart and Tirole (1990) trace the foreclosure effect of vertical integration to a commitment problem. Suppose an upstream firm supplying two downstream firms. The upstream firm could serve the downstream firms at a price equal to half the monopoly profit; however, with the absence of the capacity to commit – for example, through exclusive dealings – the upstream producer would have the incentive to renege and increase the quantity sold to one of the downward firms. In those circumstances, the downward firms would anticipate renegotiation and refuse to enter the contract unless the price charged by the upstream producer is lower; by vertically integrating with one of the downstream firms, the upstream producer would lose the incentive to supply the downstream rival and restore market power. Vertical integration may then entail market foreclosure.

Vertical integration has also been analyzed as an exclusionary strategy relying on the raising of rivals' costs. In this setting foreclosure occurs as a result of integration if nonintegrated downward competitors are not supplied with the inputs produced by the upward integrated firms or if the nonintegrated upstream competitor is preempted from selling to the downward integrated firm. For example (Salop and Scheffman 1983, 1987), a dominant firm facing a competitive fringe may integrate upward and – as long as the upstream firm has market power – raise the input price to its rivals. The final price to consumers will increase. The upstream profits will be sacrificed; however, price squeeze allows the dominant firm to extend profits disproportionately. Several objections have been raised as to the possibility of preemption by raising rival costs; once that integration takes place, the reduction in the input demand by the downward integrated firm may limit the capacity of the upward independent suppliers to

raise input prices; the integrated upward firms may find it unprofitable to refuse to deal with independent downstream firms; downward firms may find it profitable to integrate in turn. Some of these objections have been addressed in the literature; according to Ordover et al. (1990), foreclosure emerges in equilibrium whenever the downstream firm's revenue is increasing in the input price, as the profit squeeze for the downward independent firms is less than the increase in the upward unintegrated supplier profits.

Vertical integration can be also a way to practice implicit price discrimination when explicit price discrimination is banned. Suppose a monopolist – or a dominant firm – supplies two downstream firms with an input and the elasticity of the derived demand for that input is different for each firm; the monopolist would then maximize his profits by charging a higher price to the firm having a more rigid demand. If price discrimination was prohibited, the same effect could be achieved by integrating the elastic demand firm and increasing the input price to the independent firm. The result would be a price squeeze effect, since the integrated subsidiary would be able to lower price to final consumers. This argument was first set out by Stigler (1951) and then developed in various directions. Carlton and Perloff (1981) analyze vertical integration as a means to price discriminate in natural resource industries. Katz (1987) focuses on the threat to upward integration by a retail chain competing with local stores as a determinant of price discrimination; vertical integration emerges only if price discrimination is banned.

Integration and Vertical Externalities

One of the traditional defenses of vertical integration is the theory of variable proportions. A firm employing a monopolistically supplied input in variable proportions with other inputs produced by a competitive industry would substitute the monopolistically produced input by the latter, thus causing efficiency losses. The monopolistic supplier would then be able to reap profits by integrating downward and correcting the input mix. The theory was first set out by McKenzie (1951) and Vernon and Graham (1971). The

literature has debated the welfare implication of this analysis; on the one hand, vertical integration would solve the problem of inefficiency losses, thus increasing welfare; on the other hand, the higher monopolistic price for the product would cause countervailing effects. A major critique to this analysis is that integration is not a necessary condition for this result, which could be achieved by the monopolist through an appropriate pricing strategy.

Vertical integration may be welfare increasing when it avoids double marginalization. The model dates back to the pioneering article by Spengler (1950). When a firm with market power supplies an input to a downstream retailer also having market power, both the price charged by the upstream firm to the downstream retailer and the price charged by the downstream firm to final consumers will include a markup. As a result consumers will pay too high a price and final output will be “too much” restricted. If one markup could be eliminated, i.e., if retailer could price at marginal cost, final output would be increase so as joint profits. Integrating both firms can coordinate price strategies and increase both producers’ and consumers’ welfare. The avoidance of intermediate distortions presupposes market power both upstream and downstream; however, the same result is obtained if vertical integration occurs in a monopolistically competitive industry (Dixit 1983).

Vertical integration may also be a way to solve free riding problems when a manufacturer serves competing retailers providing services which are not appropriable by a single seller. The setting has been first analyzed by Telser (1960) with respect to resale price maintenance (RPM). Suppose that for the selling of a product some investment in selling activity is needed, for example, in order to inform about the technical characteristics of a product. If a seller makes this effort, the buyers can benefit from his activity but may purchase the product elsewhere where it is sold at a lower price; the possibility of free riding entails under provision of the selling activity from the retailers. In this setting the manufacturer who has an interest in that consumers be informed about the features

of the produce may prevent undercutting by the competing retailers by imposing a higher price to retailers (RPM) or integrating downward.

Incentives for upward integration may arise when a monopsonist faces an upstream competitive industry which produces an input at rising marginal cost (Perry 1978). In this model the incentive to integrate relies in the extraction of the suppliers’ rents; by acquiring suppliers one at a time, a monopsonist is able to expand the employment of the input produced by the integrated suppliers and to reduce his dependence from the unintegrated suppliers. In this process the price of the input decreases and so the independent suppliers’ rents, allowing the monopsonist to acquire upstream firms at a lower price. The monopsonist gains from this strategy are of two types: the internalization of the efficiency losses due to the underemployment of the input (efficiency effect) and the reduction of the rent component of the input cost (rent effect).

Stigler Market Equilibrium Model

Stigler’s (1951) theory of vertical integration focuses on the firm as a set of functions; firms’ decision to internalize certain function rather than acquire the corresponding services from other firms depends on the maturity of the industry, and the relation between maturity and integration is U shaped. Firms in young industries usually have to execute more tasks on their own, as they require new materials, overcome technical problems, design specialized equipment, and so on; at the early stage of industry maturity, vertical integration is then a likely outcome. However, as markets grow, some functions become sufficiently important to be provided by specialized firms, so that integration tends to decrease. Internalization takes place again in declining industries as surviving firms have to assure functions which are no longer carried out at a sufficient rate to support independent firms.

More recent contributions (Perry 1984; Green 1986) analyze vertical integration as a response to demand fluctuations in the presence of

competitive markets. When the intermediate markets are subjects to external fluctuations caused by the exogenous net supply of intermediate goods, on the one hand, firms can have incentives to integrate to avoid uncertainty and, on the other hand, they could enhance profits whenever they can respond to market fluctuations. The decision to integrate amplifies fluctuations in the intermediate markets which in turn affect the gains from integrating. Different equilibria may arise as a result of price flexibility.

Vertical Integration and Uncertainty

Other models concentrate on vertical integration in the presence of uncertainty. Arrow (1975) focuses on the uncertainty in the supply of the upstream good and on the consequent need for information by downstream firms; acquiring one or more upstream firms improves forecasts of the spot prices of the input and so the firm's ability to choose the level of capital.

According to Carlton (1979), vertical integration is a means of transferring risk from one sector to another. If the downstream firms' (the retailers) demand is random, a firm must make production decision before the demand can be observed; the derived demand which the upstream firm faces is also random. Because of the risk that the produced good goes unsold, the price of the input must exceed the marginal production cost and in this difference lies firm's incentive for forward integration; in addition integrating the firm copes with the risk of being rationed by the wholesaler, which would prevent sales. However, according to the model, vertical integration implies a lower level of expected utility because downstream firms are less efficient risk absorbers with respect to upstream firms, which causes higher total input costs in market structures with vertical integration. The lower efficiency in risk absorption in turn is due to the higher number of downstream than upstream firms; for this reason the probability that a unit of factor input will be used if it is held in the upstream firms is higher.

³High Point University, High Point, NC, USA

Definition

Actions and events occurring in the context of warfare and armed conflict that result in economic losses, physical, and/or psychological trauma. These actions and events may include, and are not limiting to, injury, loss of life, property theft and destruction, displacement, sexual assault, forced displacement or detention, torture, and participating in or witnessing traumatic actions committed against others. The perpetrators and/or recipients of such actions need not be formal institutional actors. Violence may be caused by an actor's willful intent and influence on others, or through negligence and failure to act to prevent trauma from taking place. Perpetrators of violence may also be adversely affected by actions they undertake or witness against others.

Literature

War and other forms of conflict-related violence have taken a profound toll on many people throughout the world. Between 1945 and 1999,

Fearon and Laitin (2003) estimate that over 3 million people died in 25 interstate wars and more than 16 million died in 122 civil wars in 73 countries. Although war and conflict-related violence have been examined extensively through various macro-level data collection efforts (Singer and Small 1994; Small and Singer 1982; Gleditsch et al. 2002; Collier and Hoeffler 2004; Lacina and Gleditsch 2005; Raleigh and Hegre 2005), evidence of conflict effects at the microlevel is currently limited (Blattman and Miguel 2010).

Our primary goal here is to survey recent contributions to the literature on possibly positive and negative legacies of violence. Given the importance of institutions and social norms for growth and development, the long-term consequences of war and conflict-related violence on a society's prospects for development are likely to depend on the social and institutional legacy of conflict. We will review here papers that rely on different sources of evidence, microlevel surveys, behavioral experiments, or macroeconomic datasets in order to study the social and political legacy of conflict. Table 1 lists recent studies on the relationship between violence and political and social behavior. We will review some of these studies in more detail. We find that, the findings from this literature are mixed. While a number of recent studies show that exposure to conflict intensifies certain positive prosocial elements within individuals and communities, others point to negative consequences of conflict on trust. We will attempt to shed light on these disparities by considering how individuals and communities are impacted by conflict. We find that, the effects of conflict may vary significantly depending on microlevel heterogeneity of conflict experiences.

We will not review studies of the effect of conflict on human capital outcomes, such as health or education, nor studies of the effect of conflict on physical capital and aggregate growth rates. Excellent reviews of this literature can be found elsewhere, namely, in Blattman and Miguel (2010). Instead, we focus on microlevel responses to violence. In particular, we consider the effects of conflict on prosocial preferences such as trust, because they have been found vital to solving cooperation and coordination problems and

Violence, Conflict-Related, Table 1 Heterogeneous effects of violence in political and social behavior reported in recent studies

Study authors	Year	Case/cases	Source of violence or trauma	Outcome and/or main effects	Methods	Results
Bauer et al.	2014	Republic of Georgia Sierra Leone	War	+	Experiment	Higher egalitarianism and parochialism among victimized children
Gilligan et al.	2013	Nepal	War	+	Experiment	Communities with greater exposure to violence exhibit greater levels of social capital
Voors et al.	2012	Burundi	War	+	Experiment	Individuals exposed to violence display more altruistic behavior toward their neighbors
Gneezy and Fessler	2012	Israel	War	+	Experiment	Violence increases cooperation within the group
Blattman and Annan	2010	Uganda	War	+	Survey	Formerly abducted are much more likely to engage in political life
Bellows and Miguel	2009	Sierra Leone	War	+	Survey	Violence leads to more engagement in the community, politics, and public good contribution
Blattman	2009	Uganda	War	+	Survey	Violence leads to more political participation
Bateson	2012	Large N	Crime	+	Survey	Violence leads to more participation in politics
Whitt and Wilson	2007, 2014	Bosnia	War	+	Experiment	Surprisingly high levels of out-group altruism after the war
Cassar et al.	2012	Tajikistan	War	—	Experiment	Victimization by violence undermines local trust
Jha and Wilkinson	2012	India	War	—	Macro	Communities with combat experience exhibit greater ethnic cleansing
Humphreys and Weinstein	2007	Sierra Leone	War	—	Survey	Ethnically mixed combatant groups more likely to abuse civilians
Becchetti et. al	2013	Kenya	Riots	—	Experiment	Violence leads to less trustworthiness
Beber et al.	2014	Sudan	Riots	—	Survey	Violence exposure leads to support for partition and opposing citizenship for out-groups
Nunn and Wantchekon	2011	Africa	Slave trade	—	Macro	Exposure to slave trade leads to lower trust in relatives and neighbors
Rohner et al.	2013	Uganda	War	—/+	Survey	Fighting has a negative effect on the economic situation in highly fractionalized counties, but has no effect in less fractionalized counties
Carter and Castillo	2005	Honduras	Natural disaster	+/—	Experiment	While negative shocks might promote cooperation, too large negative a shock appears to diminish it
Kesternich et al. 2014.	2014	Europe 13 countries	World War II	—	Survey	Negative effect of conflict on health and economic outcomes

(continued)

Violence, Conflict-Related, Table 1 (continued)

Study authors	Year	Case/cases	Source of violence or trauma	Outcome and/or main effects	Methods	Results
Grosjean	2014	Europe 35 countries	World War II	—	Survey	Negative legacy of conflict on political trust and perceived effectiveness of national institutions
Kim and Lee	2012	Korea	War	—	Survey	Children exposed to conflict become more risk averse as adults and more conservative politically

therefore crucial for economic and social development. Societal trust has been positively associated with growth and market development (e.g., Knack and Keefer 1997; Zak and Knack 2001; Henrich et al. 2010). Recent studies have shown how other-regarding preferences are critical for human cooperation in large groups (Bowles 2006; Boyd and Richerson 2005) and collective action (Bowles and Gintis 2006). The role of impersonal social trust in sustaining economic exchange is the object of an ever-growing literature. A prerequisite for the successful development of market economies is to depart from closed group interactions and to enlarge exchange to anonymous others (Fafchamps 2006; Algan and Cahuc 2010). In this regard, generalized trust appears as a keystone for successful market development. Generosity, a sense of fairness, and trustworthiness may also help sustain trade and cooperation in countries where institutional contract enforcement is weak by preventing contract violations. Even in countries with well-functioning institutions, trust may play an important role, given the incomplete nature of contracts. We now explore seemingly paradoxical positive and negative effects of conflict on prosocial preferences from recent studies in more detail.

On the Positive Effects of Conflict on Prosocial Behavior

Recent literature on the behavioral legacies of conflict offers surprisingly consistent evidence

of increased prosocial behavior after violence, with disconcertingly positive implications for the effects of war on social capital building. In particular, Bellows and Miguel (2009) find a significant increase in collective action among the individuals more affected by the war in Sierra Leone. Blattman (2009) reports higher voting and political action among former child soldiers in Uganda. Using lab-in-the-field experiments, Voors et al. (2012) find that individuals with exposure to greater levels of violence during the war display more altruistic behavior toward their neighbors, are more risk seeking, and have higher discount rates. Bauer et al. (2014) provide evidence of higher egalitarianism and parochialism among victimized children in the Republic of Georgia after the war with Russia, as well as among subjects victimized as children during the civil war in Sierra Leone. At the community level, Gilligan et al. (2011) find that communities with greater exposure to violence during the Maoist rebellion in Nepal exhibit more trust and higher levels of collective action. Whitt and Wilson (2007) and Whitt (2014) find surprisingly high levels of altruism toward ethnically defined out-groups among Bosniaks, Serbs, and Croats in postwar Bosnia, suggesting how prosocial norms can recalibrate quickly among former rivals and adversaries. Collectively, these studies imply that conflict may not have long-term damaging effects on prosocial norms. People can quickly recover or revert to prosocial norms once the fighting stops.

On the Negative Effects of Conflict on Prosocial Behavior

While the above research points to growing evidence of prosocial behavior after violence, some recent studies also provide cautionary evidence to the contrary. Becchetti et al. (2011) report lower trustworthiness among individuals most affected by violence in Kenya. Rohner et al. (2013) find detrimental effects of conflict on interethnic trust and trade in Uganda. The effect is particularly strong among ethnically divided communities. Nunn and Wantchekon (2011) also show that violence, and a history of violence going as far back as the slave trade in Africa, can still impact contemporary trust negatively and strongly. They find a remarkably robust negative legacy of the slave trade on general trust which they attribute to the destruction of social ties by interethnic slave raiding that took place hundreds of years ago. In 35 countries of Europe and Central Asia, Grosjean (2014) finds that victimization during World War II is, to this day, associated with lower perceived legitimacy and effectiveness of national institutions.

Using the case of Tajikistan, Cassar et al. (2013a) report the results of a series of behavioral experiments and individual surveys designed to investigate whether, more than 10 years after the end of the 1992–1997 Tajik civil war, there is any imprint on preferences and social norms that are thought to sustain the development of impersonal exchange. They find negative and persistent effects of violence on the norms that support impersonal exchange, in particular on trust within local communities. The magnitude of the effect is substantial. They find that victimization during the civil war is associated with a 40% average decrease in trust, as measured in a standard behavioral trust game, when respondents are matched to another individual from the same village. Survey-based evidence on actual behavior and stated preferences corroborates the experimental findings and points to natural consequence of lost trust: a reduced willingness to trade. Former victims are both less likely and less willing to participate in local

markets, especially when they do not have a personal connection with the trader they are dealing with. The results also indicate that experiences of victimization are associated with reinforced kinship-based norms of morality and behavior, at the expense of the rule of formal law.

However, although the net effect of conflict is negative, Cassar et al. (2013a) also find that the negative effects of violence depend on the extent to which infighting took place within local communities. Negative effects are more pronounced in regions where opposing groups intermix and where local allegiances were, and still are, split. This indicates that effects of conflict on local norms are mediated both by the specificity and the salience of wartime divides. This, in turn, may explain why the emerging literature on conflict and prosociality has found both positive and negative effects, as we now explore in more detail.

Making Sense of Conflicting Findings

Civil wars can come in many different forms. Some wars pitch socially and politically well-defined ingroups against equally cohesive out-groups. In other conflicts, even ostensibly ethnic conflicts, it is hard to identify who is ingroup and who is out-group, i.e., who is a friend and who is a foe. And in other cases, where cleavages are more based on ideology and beliefs than ascriptive characteristics, it may be nearly impossible to identify friend from foe using rudimentary visual or auditory cues. The Tajik civil conflict, in its vast majority, fits into this last category. It was characterized by localized intragroup conflict where people were unable to apply basic heuristics to identify friend from foe within their communities. As perpetrators of violence and authors of denunciations may still be close by, victims might be especially wary and guarded about whom they can trust – even years after the conflict has ended.

Cassar et al. (2013a) find indeed that the negative legacy of conflict in intra-community trust is most stringent in areas where the population was,

and still is, of intermixed political allegiance. They find that the association between conflict exposure and undermining of local trust, willingness to trade, and strength of kinship is only present in villages that are above the median in terms of political polarization but absent in villages that are below the median. They also contrast the effect in the two regional polar-opposite cases: the Pamir region where no community infighting occurred and the environs of the capital city Dushanbe, one of the most intermixed regions of the country. Consistently with the above interpretation, they find that the negative results are strongest in the Dushanbe region but absent in Pamir.

These results suggest that civil war may have particularly deleterious effects in regions where opposing groups intermixed and where allegiances are difficult to identify from basic observable characteristics. This last implication is consistent with recent findings by Rohner et al. (2013) that ethnic conflict in Uganda has hindered cohesion in ethnically divided districts but has had little effect in ethnically homogenous districts.

Another observation is that many studies of positive effects of conflict on social capital rest upon the Putnam (1995) interpretation of social capital based on incidence and intensity of group membership and participation in associations. Putnam argues that group membership (bonding social capital) fosters trust toward other groups (bridging social capital). Indeed, group membership and civic participation have been widely used in the literature as measures of social capital and positive development outcomes (for a recent review, see Guiso et al. 2010). However, social capital as group membership and association may also have negative consequences if identifying strongly with a group leads to the exclusion of outsiders (Bourdieu 1985; Portes 1998).

For example, on a positive note, Cassar et al. (2013a) find in postwar Tajikistan and Grosjean (2014) again in 35 European countries after World War II that conflict stimulates collective action and membership in social organizations (Bellows and Miguel 2009; Voors et al. 2012). However, they also shed light on the complex and dark nature of conflict-induced

social capital formation. While Grosjean (2014) reveals that victimization leads to collective action, it is of a type that appears to erode political trust. Cassar et al. (2013a) similarly find that civic engagement among victims of violence decreases trust, especially when victims of violence associate with religious groups.

In the case of Tajikistan, participation in religious groups may be perceived as a form of opposition to the secular government. In a companion paper, Cassar et al. (2013b) find that both war veterans and those who participated in fighting even after the 1997 peace agreement are significantly more active in mosque attendance and other measure of religiosity. They interpret this finding as evidence of the effect of conflict experience on fostering bonding rather than bridging social capital. These conclusions resonate with recent findings by Satyanath et al. (2013), which illustrate that a dense network of civic associations was instrumental in the downfall of democracy in interwar Germany.

Conclusion

Field research on the effects of violence on institutions and social norms is ongoing. Directions for future research include important questions about time horizons for institutional development and norm recovery after violence, the extent to which norms and institutions change when conflict is still active and ongoing, and estimating conflict effects through natural experiments and quasi-experimental designs. There is also an increasing need for replication of results from prior studies. To our knowledge, new field research projects are active or recently completed in conflict-ridden societies, for example, in Afghanistan, Bosnia, Congo, Kosovo, Pakistan, South Sudan, Somalia, Syria, Ukraine, and Yemen. With each year, the body of evidence from microlevel research into patterns of conflict effects is expanding and improving in terms of scope and sophistication in research design and linking empirical results to existing theories of violence and its heterogeneous consequences for growth and development.

At the same time, the conflict literature faces major identification problems. It is virtually impossible to find perfect randomization of treatments (such as exposure to victimization) in naturally occurring field settings. In the absence of such ideal conditions, a multitude of less-than-perfect observational studies pointing to similar conclusions are still better than nothing at all.

In conclusion, we believe that more clarification of ingroup/out-group identification problems could help explain why some conflict studies find dramatic rebound and recovery of social norms, while others observe lasting detrimental legacies of violence.

Violence, Interpersonal

Pauline Grosjean

School of Economics, University of New South Wales, Sydney, NSW, Australia

Definition

Interpersonal violence is the intentional use of physical force or power, threatened or actual, against another person that results in a high likelihood of injury and/or death. In what follows, we will abstract from psychological forms of abuse and from sexual violence and focus on assault and homicide.

Interpersonal Violence: Roots, Remedies, and Consequences

In the *Leviathan*, published in 1651, Hobbes famously described the pervasiveness of interpersonal violence in the absence of a strong state. He wrote that “during the time men live without a common power to keep them all in awe, they are in that condition which is called war, and such a war as is of every man against every man.” He

also evoked some of its consequences and in particular the fact that “in such condition there is no place for industry.”

In what follows, I will discuss the following: (i) why agents resort to interpersonal violence, with a focus on the economic origins of interpersonal violence; (ii) how violence is tamed and, in particular, why interpersonal violence has declined so steadily since the emergence of strong states during the Middle Ages in the Western World; and (iii) some of the consequence of violence on economic activity. We will see, as was already discussed by Hobbes, that the origins, prevalence, and consequences of violence are intricately linked to the nature and quality of the state.

The Roots of Violence

Until recently, economists have essentially focused on the defense of property rights and its converse, expropriation, as a motive for violence. As described by Hobbes, if the state is absent or too weak to enforce property rights, agents have to take matters into their own hands. Violence by individuals creates a “semblance of property rights” to use the words of Skaperdas (1992) and becomes a substitute for formal law enforcement. At equilibrium – an equilibrium of fear – property rights are sustained by respective investments in power and by the threat to exercise this power.

A common prediction of these models focused on expropriation is that actual force is used in equilibrium only in the presence of bargaining inefficiency, as in Gonzalez (2010) or in the presence of incomplete information, as in Donohue and Levitt (1998) or in Aney (2012). Otherwise, if every agent knows who the strong party is, it is better to concede rather than fight, since fighting is costly.

Castillo et al. (2013) provide an empirical validation of the theoretical intuitions concerning the link between expropriation motives and violence. They show, in the context of the Mexican drug trade, that higher incentives to exert violence due to a sharp rise in the price of cocaine due to large seizures of cocaine in Colombia (Mexico’s main cocaine supplier) between 2006 and 2010 account for 21.2% and 46% of homicides and drug-related

homicides, respectively, in Mexico. However, in the context of more advanced economies with better formal law enforcement such as the United States, Levitt (1999) finds that violent crime is not responsive to increases in predation motives generated by widening inequality between rich and poor.

Other papers have recently introduced other motives for violence in addition to direct expropriation. Chassang and Padro-i-Miquel (2010) show how the presence of uncertainty introduces a new motive for violence: preemption. Players, while second-guessing each other's moves, may decide to attack in order to avoid suffering a debilitating surprise attack from an opponent who is expected to be aggressive. Reputation is another major motive for violence. This is formally illustrated by Silverman (2004) and Ghosh et al. (2013), who develop reputation-based theories of crime and violence in dynamic games of incomplete information. Silverman (2004) shows that in an environment with incomplete information, agents may want to behave violently in order to build a reputation for being tough and deter future attacks. This "culture of violence" equilibrium prevails if the cost of participating in crime is low enough, for example, if the state is weak or absent.

The reputation motive for violence is also stressed in sociopsychological explanations of violence. In a famous and debated hypothesis, Nisbett and Cohen (1996) argue that the Southern culture of honor is rooted in the original settlement of the backcountry of the United States by settlers from the fringes of Britain, the Scottish Highlanders, and the Ulster Scots-Irish, who were traditionally practicing pastoralist agriculture. Cultures of honor, which rely heavily on aggression and male honor, are common adaptations among populations that depend upon easily stolen herds. Grosjean (2014) stresses another element, in addition to pastoralism, which explains why eighteenth century Scottish Highlanders and Scots-Irish were more prone to interpersonal violence than other Western European settlers. They originated from areas where formal states were weak and where the concept of state-administered punishment for crime was foreign (O'Donnell

2005). Lawlessness, lack of political centralization, and violence had characterized the Anglo-Scot borderlands for much of the 250 years during which Scotland and England were in open conflict with one another (from 1296 to 1551). Ulster, the last Irish province to come under English domination, had been particularly ravaged by the Nine Years' War and left in a power vacuum by the Flight of the Earls in 1607. In the absence of third-party law enforcement, aggression and a willingness to kill can be essential to build a reputation for toughness and deter animal theft.

Sociopsychological and economic theories based on reputation differ from previous expropriation models in that they move away from the immediate costs and benefits of exerting violent acts into the concept of a "culture" of violence. Evolutionary anthropologists argue that rules of dispute resolution belong to the set of culturally transmitted norms of behavior, that is to say preset behaviors that save on the cost of developing new responses to changing environments (Paciotti and Richerson 2002; Richerson and Boyd 2005). The absence of formal law enforcement entails the prevalence of self-help justice, which is sustained by specific cultural traits – the culture of honor being a particular example.

Grosjean (2014) formally tests Nisbett and Cohen's (1996) culture of honor hypothesis. Combining contemporary homicide data with historical census data, she finds that Scot or Scots-Irish historical presence contributes to higher homicide and aggravated assaults in the United States, even to this day. Consistently with a culture of honor, the effect is specific to white offenders and to a type of homicide that aims at the defense of one's reputation: between acquaintances and perpetrated with a handgun, pistol, or, in an even more demonstrative way, a blunt object, such as hammer or club. The persistence of this violence over more than 200 years is taken as evidence of the existence of a culture of violence. The author finds direct evidence that such violent cultural traits are inheritable and were transmitted within families to subsequent generations of people of Scots-Irish ancestry.

However, Grosjean (2014) finds that the relationship between historical Scots-Irish presence and contemporary interpersonal violence is observed in the South only. She hypothesizes, and confirms, that the historical presence of Scot or Scots-Irish herders is associated with higher homicide only in areas where the quality of formal institutions was low. The interpretation is that a culture of violence exists but, more importantly, that it does not exist in a vacuum. In particular, persistence has vanished where formal institutions were strong. The following subsection describes why that might be the case.

Taming Violence

The premise of the argument made so far lies in the relationship between lawlessness, economic vulnerability, and interpersonal violence. Violence plays an essential role for the defense and enforcement of property rights in the absence of third-party enforcement. It follows that better third-party enforcement should unravel violence.

The development of formal, state-based institutions guarantees the security property rights and provides alternative means of dispute adjudication. It therefore lowers the returns to interpersonal violence. The development of the state also increases the costs of interpersonal violence, since the monopolization of violence by the state goes hand in hand with the penalization of interpersonal violence (Weber 1958). This provides the foundation for a negative relationship between state development and the prevalence of violence.

The fact that state development unravels not only violence but also cultures of violence is at the heart of Elias's "civilizing process" (Elias 1994). According to this theory, cultural norms reflect the social structure. As the state develops and monopolizes violence, violent instincts and the inclination to solve disputes with fists, sticks, blades, or guns are gradually placed under an increasingly strong social control.

Pinker (2011) provides abundant historical evidence consistent with the view that interpersonal violence has been steadily decreasing since the

emergence of strong states in Europe in the Middle Ages. Detailed empirical studies are provided by Grosjean (2014), Couttenier et al. (2014), and Restrepo (2014). We have already reviewed Grosjean's (2014) result that the Scots-Irish culture of honor persisted only in areas of the United States where formal institutions were weak. Restrepo (2014) shows that areas of Canada with a weaker monopoly of force by the state at the time of European settlement were historically more violent and still are more violent – despite the later consolidation of the Canadian state. Couttenier et al. (2014) exploit the fact that some mineral discoveries occurred sometime before and sometime after governmental territorial expansion in the West of the United States and compare these two distinct institutional contexts. They find that when discoveries predated the establishment of the state, they were associated with higher levels of interpersonal violence. These differences have persisted over time. Today, still, places with "early" historical mineral discoveries experience homicide rates 40% higher than the sample average, even though, obviously, the state is now fully consolidated in these places. In contrast, no effect is observed if discoveries occurred after the state was established. These differences hold even when comparing discoveries that occurred within short time intervals from one another, either just before or just after incorporation. These findings speak for the importance of the quality of formal institutions for determining whether violence takes root: even short-term variations in the institutional environment can generate large differences in the prevailing levels of interpersonal violence, and these differences persist over time.

The question of how the monopolization of violence by the state comes about is beyond the reach of this article, but interested readers can be referred to a recent empirical study by Sanchez de la Sierra (2014) on the determinants of state formation in the Democratic Republic of Congo.

When the state's monopoly violence is incomplete, individuals can take matters into their own hands (man against man as expressed by Hobbes),

but specialized groups can also emerge as a substitute for the state to provide property rights security. This is essentially Gambetta's (2003) theory of the emergence of the Sicilian Mafia. He argues that the Mafia arose to substitute for formal, state-based property rights enforcement after the collapse of the Bourbon Kingdom in the nineteenth century. This idea is investigated empirically in a recent paper by Buonanno et al. (2012). At the time the state collapsed, the price of sulfur – Sicily's most valuable export – was soaring due to rising demand on international markets. The Mafia provided alternative means of property rights security. Buonanno et al. (2012) show that the Mafia took root in areas that were richest in sulfur, around the time the Bourbon Kingdom collapse created a high demand for property rights protection by Sicilian landlords.

The Mafia is not the only type of organization that can provide alternative means of property rights security when the state is absent or weak. Drug cartels and militias are others. In that regard, Dell (2011) and Castillo et al. (2013) provide fascinating studies of the interplay between state policies and cartel behavior. Both study the consequences of the United States and Mexican Drug War on cartel behavior. As in previously cited studies of the Mafia, cartel activity is proxied by the number of homicides. Dell (2011) provides a careful analysis of the political economy game between local authorities and drug cartels in Mexico to explain the sharp rise in drug trade-related violence in Mexico since 2007, which has claimed 50,000 lives. She shows that the crackdown led by Mexico's conservative National Action Party (PAN) has had a direct and positive effect on the level of prevailing violence. Using a regression discontinuity framework between closely contested local elections, in which it can be assumed that who wins office – and hence the intensity of repression – is randomly assigned, she shows that PAN's victories and the associated repression are systematically associated with a subsequent rise in homicide. She explains this phenomenon by the fact that the state's repressive policies weaken the position of the dominant drug

cartel and open the way for a war for dominance between cartels.

Angrist and Kugler (2008) document that exogenous increases in coca prices increase violence in rural districts in Colombia because combatant groups fight over the additional rents. Similarly, Castillo et al. (2013) show that violence exerted by Mexican cartels increases when the price of cocaine rises. Interestingly they find that violence is highest in locations contested by several cartels, that is to say areas where each cartel is furthest away from enjoying a monopoly of violence, a result that resonates with Dell's (2011) interpretation.

Violence and organized crime are commonly perceived as a severe obstacle to the economic development of several regions around the world, for instance, Latin American countries such as Mexico and Colombia or former republics of the Soviet Union. The next section reviews some of the negative economic consequences of violence and organized crime.

The Consequences of Violence

Besides the immediate costs of violence in terms of loss of lives, physical injuries, and psychological trauma, violence, or the threat of violence, also disrupts economic activity. We will review several studies that try to estimate the cost of violence. As we will see, this is an arduous task because it is difficult to separate the effect of violence itself from that of what gives rise to violence in the first place, that is to say insecure property rights and a weak rule of law. Indeed, several studies document the direct negative effects of institutional quality on economic growth and development (see the seminal study by Acemoglu et al. 2001). Making matters even more complicated, as we will see, is that violence itself can cause institutional quality to deteriorate even further.

The most immediate costs of violence consist obviously in loss of life and other bodily or psychological damages. Besides a few studies that try to estimate the value of statistical life – with sometimes widely varying estimates (see Leon and Miguel 2013) – economists have mostly focused

on the costs in terms of economic growth and development.

The first underlying mechanism through which violence negatively affects economic growth and development is expressed by Hobbes in the opening quote: violence or its threat leaves little place for “industry” because it makes the fruit of labor uncertain and hence reduces incentives to invest.

BenYishay and Pearlman (2013) estimate the impact of homicide-related deaths during the drug war in Mexico on the labor supply of the general population. They find that the increase in homicides has reduced average hours worked by 1–2%. They conclude that the fear of violence can lead to behavioral changes that lower economic activity.

Even in the context of more advanced economies, the direct economic costs of violence or their indirect costs, through several behavioral changes in the labor market, are substantial. In the United States, Hamermesh (1999) finds that higher rates of homicide explain declines in evening and early morning work and that these shifts resulted in losses on the order of four to ten billion dollars. Pinotti (2011a) estimates the impact of the presence of organized crime in Southern Italy on GDP. Applying a synthetic control approach, he compares Mafia-stricken regions to a weighted average of other regions that are otherwise similar in terms of industrial structure and outcomes prior to the rise of organized crime in the 1970s. He finds that the presence of the Mafia has lowered GDP per capita by 16% in Mafia-stricken regions.

A related question deals with the distribution of these costs across different segments of society. The few studies dealing with this issue find that it is the poor who bear the bulk of the costs of violence. In Mexico, BenYishay and Pearlman (2013) find that the negative impacts of violence on hours worked are larger for the self-employed who work from home, generally small-scale artisans and shopkeepers. Still in Mexico, Ajzenman et al. (2014) find that the impact of violence on housing prices is borne entirely by the poorer sectors of the population. They find that an increase in homicides equivalent to one standard

deviation leads to a 3% decrease in the price of low-income housing.

The decrease in GDP in Mafia-stricken regions of Southern Italy documented in Pinotti (2011a) is primarily driven by a contraction in private investment. While in principle, public investment could substitute to foregone private investment, Pinotti (2011) shows that this process is incomplete, what results in a net aggregate deadweight loss. First, he finds that an increase in public investment has not fully compensated the decrease in private investment. Second, this public investment was relatively inefficient and in fact further distorted by the presence of the Mafia.

This second result is explored in more details in a follow-up paper by Pinotti (2011b), which shows that Mafia presence has a direct negative effect on the quality of institutions and more precisely on the quality of politicians. The theoretical intuition is found in Dal Bo et al. (2006) who argue that the presence of criminal organizations deters high-quality politicians from running for office, as they anticipate that their political action might be constrained or distorted by criminal organizations and that their life could be endangered if they were not ready to compromise with criminal organizations. As a result, only dishonest politicians who are ready to bend down to the wills of organized criminal groups are left to run for office.

Pinotti (2011b) finds empirical support for this prediction. Politicians in Southern Italy who are appointed during more violent elections, in which the Mafia is presumably more active, exhibit on average a higher probability of being subsequently involved in scandals. They are also much less likely to hold a college degree.

Couttenier et al. (2014) document a related “curse” of homicide-related violence on the quality of judicial institutions in the historical context of the United States. They find not only that mineral discoveries that occurred before the consolidation of the state are associated with more violence but also with a lower quality of (subsequent) judicial institutions. Using a historical panel dataset of judicial quality indicators at the state level, they find that mineral discoveries are associated, yearly, with a reduction by

between 2% and 5% in the quality of judicial institutions.

The effect of institutional quality on growth and development has attracted a large literature, since the seminal studies by Engerman and Sokoloff (1997) and Acemoglu et al. (2001). More recently, scholars have also focused on the positive role of social norms of cooperation and trust, and social capital in general, for economic prosperity (see Knack and Keefer 1997). In this dimension also, the consequence of violence is dire. For example, Nunn and Wantchekon (2011) show that ethnic groups that were most severely affected by the violence associated with the slave trade in Africa still display lower levels of trust and have lower social capital, to this day.

These destructive effects of violence on formal and informal institutions provide additional channels through which violence negatively affects economic growth and development.

Conclusion

The literature reviewed here describes interpersonal violence as the outcome of a cultural-institutional arrangement, in which violence, or its threat, is a response to the need to protect and enforce property rights when formal institutions are weak or absent. Even though improvements in third-party enforcement could unravel this unfortunate equilibrium, in practice this is very difficult to achieve. This is because improvements in formal institutions are hard to come but also because the violence itself causes the quality of political and judicial institutions to worsen even further, thereby feeding the initial vicious circle.

On a more positive side, a couple of papers find that it is possible to break out of this vicious circle. Grosjean (2014) finds that a culture of violence by eighteenth century Scots-Irish settlers was not transmitted to further generations in areas where settlers faced strong formal institutions. Voigtländer and Voth (2012) also find that anti-Semitic attitudes disappeared in the most active trading regions of Germany where the cost of discriminating against outsiders was high.

Voting Power Indices

Manfred J. Holler

Center of Conflict Resolution (CCR), University of Hamburg, Institute of SocioEconomics (ISE), Hamburg, Germany

Abstract

This entry introduces Shapley-Shubik index, Banzhaf index, Deegan-Packel index and Public Good Index. It discusses the properties of these measures of a priori voting power focusing on monotonicity. Applications are listed.

The Indices

On the occasion of the 1787 Constitutional Convention held in Philadelphia, Luther Martin, a Maryland delegate, complained “that the voting power of the large states in the US House of Representatives would be disproportionately too large compared to that of the small states, assuming that the representatives of each of the 13 states would always vote as a bloc” (Felsenthal and Machover 2005, p. 486). He observed that the seat shares are a pure proxy of the a priori voting power, i.e., the voting power that abstracts from political ideologies, personal preferences, geographical and cultural closeness, etc. and considers seats shares and the decision rule (e.g., a majority quota q), only. For an illustration, let us assume $q = 51$ and the seat distribution is $w = (48, 46, 6)$. Can we conclude that the first bloc of voters, controlling 48 seats, is 8 times as powerful as the third bloc controlling 6? In fact, we may ask whether it is more powerful at all. Voting power indices try to answer to such questions, discussing voting situations in the form of a weighted voting game (or, more general, in the

form of “simple games”) that assigns to a winning coalition a value of 1 and to a losing coalition a value of 0. The blocs of voters labeled players and their vote shares are identical to the weights.

Luther Martin measured the a priori voting power of state i by the number of possible minimum winning coalitions (MWC) that have i as a member. A coalition S is a MWC if S is losing if one of its members is leaving this coalition. As a consequence, all members of a MWC are critical to its winning, i.e., are “swing players.” This measure has been reintroduced by Holler (1982) under the label of Public Good Index (PGI) and axiomatized in Holler and Packel (1983) without being aware of Luther Martin’s proposition. Already before, Deegan and Packel (1979) have introduced a hybrid form based on MWCs: the Deegan-Packel index (DP). Their measure divides the benefits of winning by the number of players in the particular MWC. This implies that it treats the value of a coalition as a private good.

There is another case of reintroduction. In 1946, Lionel Penrose proposed a power measure that, to determine the a priori voting power of i , counted all coalitions S which had i as a swing player. Therefore, to contribute to the power value of S , i had to be critical for the winning of S , but S can have surplus voters, i.e., voters that have no impact on the winning or losing of S . This measure became popular as Banzhaf index (Bz) only when Banzhaf (1965) reintroduced it, and the measure was applied to the design of real world juries. For the latter, see Grofman and Scarrow (1979).

The favorite power measure for many game theorists, especially if they have some mathematical inclination, is the Shapley-Shubik index (SS) which applies the Shapley value (Shapley 1953), a solution concept for cooperative games, to situations of weighted voting. Shapley and Shubik (1954) is the corresponding paper. A straightforward calculation is to list all permutations (i.e., orderings) of voting blocs and, starting from the left side, give the bloc i that turns a losing coalition into a winning coalition, called pivot, the value 1. The values get normalized such that the values of all players add up to 1. Note that there are $n!$ permutations if there are n

players. However, there is a rather sophisticated formula that can be used as a shortcut. The formula is based on answering the question: What is the probability that a specific pivot i is in the ordering positioned exactly where it is?

One of the beauty of SS is that power weights can directly be interpreted as probabilities to affect the outcome – this relates to Max Weber’s notion of power “as the chance of a man or of a number of men to realize their own will in a communal action even against the resistance of others who are participating in the action” (Weber, 1948[1924], p.180).

The Right Index

There are at least another dozen of voting power indices discussed in the literature. This raises the question which is the right index. One way to answer this question is to look into the underlying stories and accept that alternative measures are meant for alternative issues. For instance, Bz and PGI are meant to measure the influence of voters, while SS and DP imply a sharing. However, the formal analysis is not conclusive. Alternatively, the measures are discussed with respect to their properties. Of course, the underlying axioms give some insights. Yet, more popular arguments refer to paradoxes and, more specifically, failures in satisfying monotonicity. PGI and DP do not satisfy local monotonicity (LM), i.e., it can happen that a player i with a larger vote share than player j gets assigned a smaller power value than j . For instance, given a vote distribution $w^\circ = (35, 20, 15, 15, 15)$ and a majority quota 51, the PGI values are $h(v^\circ) = (4/15, 2/15, 3/15, 3/15, 3/15)$. The player with weight 20 shows a lower value than the players with weights 15. Such a reversal, indicating a violation of LM, cannot happen if we apply Bz or SS as long as there are no a priori unions considered and coalitions and permutations, respectively, enter the calculation with equal weights (See Alonso-Mejide et al. (2009)). In a recent publication, Freixas and Kurz (2016) suggest a class of new indices that result out of convex combinations of PGI and Bz index such that LM is satisfied.

Both SS and Bz (as well as PGI and DP) suffer of the paradox of redistribution: If we redistribute the vote shares such that the vote share of player i increases, it can happen that i 's power value decreases. A classical discussion of paradoxes we find in Brams (1975). However, one might wonder whether it makes sense to compare power indices to vote distributions, in order to evaluate the properties of the indices, when Luther Martin observed already that seat shares are a pure proxy of (a priori) voting power. Under the assumption that the election outcome is represented by the seat distribution, which is not a trivial to achieve (see De Meur and Gassner 1987; Gambarelli and Palestini 2013), the seat distribution could serve as norm that should be equalized by voting power. Equalization can be achieved (or at least approximated) by a reshuffling of seats or by the choice of decision rule. Berg and Holler (1986) and Holler (1985) proposed a randomization over alternative decision rules to equalize voting power and seat distribution (See Turnovec 2011). Of course, with the strict correspondence of power and seat shares, the violation of LM and the paradox of redistribution is avoided. However, this does not answer which index to choose.

Applications

Earlier applications of voting power indices focused on both the US legislation – characterized by the interrelationship of Senate, Congress, and President – and the UN Security Council (see, e.g., Shapley and Shubik 1954). Over the last thirty years, however, numerous articles have been published on the power distribution in EU political institutions, i.e., Council of Ministers and the European Parliament, and their interplay (although with the Commission), e.g., in the co-decision procedure. Each of the two collection of papers Holler and Owen (2001) and Holler and Nurmi (2013) contains a section on “Voting Power in the European Union” “presenting five, respectively, six highly relevant articles. (See list of Further Reading below.) Moreover, there are the two volumes of *Homo Oeconomicus*, in honor of Hannu Nurmi

(Holler and Widgrén 2009; Holler et al. 2011), which contain a number of contributions on this subject. In addition, I would like to recommend Napel and Widgrén (2011) which analyzes the voting power in the EU Council of Ministers for the consultation procedure and compares the results with the outcome of a noncooperative (strategic) game designed accordingly. For the latter, (political) preferences have to be assumed, and thus the a priori of the power indices does no longer apply. However, in the given study, power indices delivered a good approximation of the “relative strategic power” of the noncooperative analysis.

There is also voting in bureaucracy, at university, and in business. Gambarelli and Pesce (2004) observe that the application of power indices allows the investor to define his power of control on the basis of the number of shares owned (See also Gambarelli and Owen 2002).

Wealth Maximization: Efficiency and Equality Considerations

Yew-Kwang Ng
Department of Economics, Nanyang
Technological University, Singapore, Singapore
School of Economics, Fudan University,
Shanghai, China

Abstract

Posner's proposal for wealth maximization in judiciary decisions has not been widely accepted, but the influence of the economic analysis of law it propelled has increased tremendously. In the face of criticism, Posner himself has retreated into a pragmatism with wealth maximization not the only principle used. This leads to a lack of both moral justification and consistency. This entry shows that, if not used as the ultimate objective, but as an instrument for welfare maximization, wealth maximization is much more acceptable, if it is also supplemented by appropriate redistribution in the general equality policy. This is especially so as efficiency supremacy in specific

issues including the judiciary (close to wealth maximization) would then make every income group better off. This is so despite the presence of disincentive effects in general redistribution. The separation of the judiciary and the legislative may then also be justified.

Introduction

Around four decades ago, eminent judge Posner (1973, 1979) pushed the interest in law and economics to a new height by proposing the use of wealth maximization in the judiciary. Posner proposed this principle both for descriptive/scientific analysis and proscriptive/normative guidance. In his own words, it “provides a good explanation of many common law rules and principles . . . [and also is] an ethically attractive guide to social policy, especially in the common law context” (Posner 1980a, pp. 243–244). The proposal led to intense discussion both on descriptive/scientific accuracy and the proscriptive/normative acceptability in the 1980s and after (e.g., Dworkin 1980; Kronman 1980; Veljanovski 1981; Mathis 2009; Campbell 2012). Recent interest and controversies in the issue continue (e.g., Driesen and Malloy 2015; Fernandes 2015; Hatzis and Mercuro 2015; Pino-Emhart 2016; Posner 2015). Despite the widespread nonacceptance of Posner's proposal especially at the normative level, the influence of the economic analysis of law has grown spectacularly (e.g., see Hatzis and

Mercuro 2015, Preface). Under severe criticisms, Posner himself has, since as early as the mid-1980s, retreated from wealth maximization as the single principle, into a pragmatism of admitting different considerations (“wealth maximization as an incomplete guide,” Posner 1985, p. 101; see also Mathis 2009, ch. 8), if not into an “anti-theoretical populist” position (Fernandes 2015, p. 210). This pragmatism is conceptually unsatisfactory as it does not provide some appropriate tradeoffs between the different considerations. In my view, some ultimate guide such as utilitarianism or its generalization (welfarism, which is utilitarianism without necessarily the maximization of the unweighted sum of net welfare) is desirable, at least at the more ultimate level of the long-term choice of what rules/principle/rights to accept and impose.

The present entry shows that, if “wealth maximization” is used not as the ultimate objective, but as a qualified instrument for some intrinsic objective (e.g., welfare maximization), it will be much more acceptable. Though Posner himself has also moved towards the instrumentality of wealth maximization (e.g., see Mathis 2009, Sub-section 8.4.4.3), he has provided neither the ultimate objective the instrument is clearly for, nor an adequate justification. Posner appears to be both rejecting and citing the support of utilitarianism. His criticism of utilitarianism is valid only against a very naïve version that ignores indirect effects. Taking account of these effects, utilitarianism is consistent with most widely accepted individual rights and constitutional provisions.

However, wealth maximization itself is not sufficient for welfare maximization. It has at least to be supplemented by the promotion of equality. Nevertheless, from the principle of treating a dollar as a dollar (efficiency supremacy) **in specific issues** (Ng 1984), the role separation between the legislative and the judiciary, as mentioned by Posner (1990, p. 101f.), may be justified. Posner justifies the separation on the ground of the lack of “flexible instruments for redistribution” by courts; “Courts can do very little to affect the distribution of wealth in a society” (Posner 1984, p. 132). Here we go further, arguing for refraining from redistribution even if the judiciary

is capable in doing so, at least on specific issues including judiciary decisions, leaving redistribution to be done in the general equality promotion policy. The focus of the judiciary on efficiency then comes close if not exactly coinciding with Posner’s wealth maximization. Despite the prospering of the economic analysis of law in the academia, “Law and Economics seems to be dying in tort law, at least as a normative principle” (Pino-Emhart 2016, concluding paragraph). The acceptance of our argument here may help to revive law and economics in this respect. Put it differently, the critics of Posner may have won the battle in this front, this entry tries to make Posner winning the war, at least in terms of wealth maximization for welfare maximization.

As pointed out by Mathis (2009, Section 8.6), Posner himself had retreated into a pragmatism of “rapprochement towards utilitarianism,” with “division of labour between the judiciary and the legislature,” and effectively using wealth maximization as a nonexclusive instrument. Thus, in a sense, the present entry is much in line with Posner’s later position. However, it provides a more consistent defence from the level of moral philosophy (intrinsic values) to that of practical policy, with deeper analysis, especially regarding the issue of equality or distribution.

To focus on our main points within an entry, we largely ignore some complications like the difference between the willingness to pay and the willingness to accept (or between offer and asking prices), loss aversion, endowment effects, etc. For simplification, we will also largely use an a-temporal analysis except when intertemporal issues are directly discussed, thus largely ignoring such issues like the difference between stocks and flows. Posner’s failure to adequately distinguish between ex ante compensation and hypothetical compensation (Posner 1980b), the “naturalistic fallacy” (Mathis 2009, p. 164) of violating Hume’s law, and other methodological ambiguities that have been discussed by others (e.g., Mathis 2009, ch. 8; Campbell 2012) will also largely not be covered here. On the issue of compensation, the actual loss of a lottery ticket buyer may be said to be ex-ante consented to (hence compensated for in a sense) at the time of buying

the ticket, but many losses of those made worse-off by using the Kaldor-Hicks criterion or wealth maximization with hypothetical, but not actual compensation cannot be said to be similarly consented to.

Though the issues of distribution/equality and that wealth cannot be an ultimate value that are focused here have also been discussed before (e.g., Dworkin 1980; Mathis 2009, ch. 8), this entry pushes the discussion to a deeper and more comprehensive level to provide a more adequate basis for making wealth maximization acceptable as an instrument for welfare maximization. In particular, instead of equating wealth maximization with the acceptance of the Kaldor-Hicks criterion (Posner 1980a, p.244), we argue for wealth maximization in specific issues, showing that, when supplemented with appropriate redistribution, all income groups will be made better off. This provides a much stronger basis than the Kaldor-Hicks criterion.

Wealth Maximization for Welfare Maximization

Posner (1979, 1980a) rejected utilitarianism and proposed wealth maximization to replace utilitarianism. Obviously, wealth maximization differs from utilitarianism or welfare maximization. A very large amount of wealth, if very unequally distributed, with the majority starving, may clearly be a situation of very low welfare. Thus, wealth maximization cannot be an acceptable ultimate objective. I have defended utilitarianism and welfarism elsewhere (Ng 1975, 1990, 2016; the last specifically against Posner's arguments). This section shows how wealth maximization may be used (with supplementation) for welfare maximization. Since wealth is not intrinsically valuable while welfare is, this is a much reasonable position to take. In fact, perhaps in the back of his mind, Posner may also have something similar. In the concluding paragraph of his 1979 paper (p. 136), he proposed a system that "provides foundation and accommodation both of individual rights and of the material prosperity upon which, in the modern world, the happiness of most people

depend." This sounds like welfarism. A welfarist also wants material prosperity and individual rights for the pursuit of happiness.

The obvious deficiency ("monstrousness") of wealth maximization without appropriate supplementation is that a large amount of wealth, if very unequally distributed, may still be disastrous. Thus, an obvious way to supplement wealth maximization is to achieve an appropriate, usually more equal, distribution. Whenever distribution is too unequal, especially when some individuals are too poor, redistribution is made to avoid disastrous outcomes. More appropriately, redistribution policies are used routinely to avoid extreme inequality and poverty. Many such policies are in fact maintained in most high-income countries in the form of progressive income taxation and welfare spending including unemployment benefits. In the presence of such supplementation, wealth maximization may be pursued in specific areas, including the judiciary as advocated by Posner, with all income groups, the rich and the poor alike, being made better off, as shown below.

If redistribution may be carried out costlessly, it is clear that wealth maximization makes sense, at least when only economic issues are involved. The highest feasible amount of wealth should be achieved, and then redistribution may be carried out to achieve the highest level of social welfare. Redistribution is of course not costless; substantial costs include administrative, compliance, and policing. However, economists emphasize the efficiency costs of distortion or disincentive (which is a distortion in the work-leisure choice). Especially for high-income countries, this emphasis makes sense, as the essential costs of raising government revenues and some basic public spending are largely given. Choices involve only the extra costs of raising more or less revenues. Then for these relevant *marginal* costs, the disincentive effects are the more important costs. Focusing on the efficiency costs of disincentive effects of tax/transfer, it is argued below that using the rule of efficiency supremacy or wealth maximization in specific issues (including in the judiciary) may be justified.

Roughly speaking, in specific issues, we should use efficiency supremacy ("a dollar is a

dollar irrespective of recipients”) to maximize the total social wealth. We then also use appropriate redistribution to achieve some desirable level of equality. What about the costs of redistribution? Despite substantial costs of redistribution, the case for efficiency supremacy in specific issues is not compromised. Though redistribution using tax/transfer to achieve equality has substantial disincentive effects, the pursuit of equality in specific issues like judiciary decisions also has the same degree of disincentive effects, if the degree of equality (in real incomes) achieved is the same. This is so because in the work-leisure choice of a rational person (irrationality may cause divergences either way and will likely net out to be negligible), not only will the tax/transfer system (its degree of progressivity or the marginal tax rates at the relevant income levels in particular) be taken into account, but the effective redistributive effects in specific issues will also be taken into account. It is true that information will be imperfect, but again the effects of this imperfection may go either way and will likely net out to be negligible. This is so because people (extreme misers possibly excepted) do not earn incomes for incomes sake but to gain utilities. When you earn higher incomes, if the extra money cannot be used to buy convenient parking spaces (distributed by first-come-first-served instead), the values gained by earning extra incomes will be discounted, equivalent to having a higher marginal income tax rate. Whether we achieve a given degree in equality (in real income or utility) by the tax-transfer system or by additional inefficient but pro-equality measures in specific issues including judiciary decisions, the same degree of incentives will prevail. However, the violation of efficiency supremacy will involve additional efficiency costs and hence is inferior.

For any system using a particular tax/transfer schedule and some inefficient but pro-equality measures in specific issues, we may dismantle these inefficient measures but at the same time make the tax/transfer schedule more equality oriented or more progressive. This could be done in a way that the combined effects are to make every income groups indifferent after and before this change in policy. As we then have the same utility

distribution over groups of people of different earning abilities, the same incentive effects will prevail for all groups. As the change is to dispense with inefficient measures, the government could impose more taxes than it needs to give more subsidies, in order to make all groups indifferent to before the change. The efficiency gain of this efficiency supremacy system then manifests in having a higher government net revenues which could be used to make all groups better off. This result was proved rigorously as a proposition and published in one of a few, if not the very top journal in economics, the *American Economic Review* (Ng 1984). It is somewhat ironical that, right in the heyday (early to mid 1980s) of the criticism of Posner’s wealth maximization, a proposition was proved that is most supportive of Posner’s position, but no one seemed to realize this connection for three decades. (See however Kaplow and Shavell (1994) on the superiority of using income tax/subsidy than the legal system in redistributing income.)

As all groups are made better off, this is at least a quasi-Pareto improvement. It is only quasi, because, in the presence of heterogeneous preferences of different individuals within the same income group, we may not be able to ensure that no one is made worse off. However, those made worse off could be compensated by the gainers within the same income group. This makes the quasi-Pareto change satisfying the Kaldor-Hicks criterion within each and every income group. As the compensation test in the original Kaldor-Hicks criterion is only hypothetical, it may not be widely acceptable if applied across all income groups. If the very rich are made better off by \$10 billion and the very poor are made worse off by \$5 billion, and the compensation is not actually carried out (with the actual compensation, the change would be a Pareto improvement), the result, even if wealth increasing, may be very welfare reducing. However, our quasi-Pareto change here satisfies the compensation test within each and every income group. It is thus much more acceptable as a sufficient condition for a social improvement than the Kaldor-Hicks criterion.

Our argument here may be illustrated using the UPF (utility possibility frontier) curves. In Fig. 1

Wealth Maximization: Efficiency and Equality Considerations, Fig. 1 Disincentive effects

and starting from a situation at point A, it is tempting to think that, if a specific judiciary decision will move us from A to B, it may be welfare improving. Despite the lower wealth or the lower efficiency involved (the UPF through B being lower than the UPF through A), the higher degree in equality at B may make it to be on a higher welfare contour than A. Choosing between A and B as the final point, I would also choose B. However, starting from A, instead of making an inefficient or wealth-decreasing move to B by a decision/policy on a specific issue, we would be better off trying to increase equality from A, aiming at C. If redistribution is costless and C is attainable, it is Pareto superior to B. Everyone will agree that this is a better move. However, in the presence of redistribution costs, it is not feasible to move from A to C. We can only travel from A along the broken utility feasibility frontier (UFF) to D. If the disincentive effects are substantial, D may be Pareto-inferior to B. Does this make the inefficient move from A to B desirable? The answer based on the analysis of this section is: No! The reason is that, if redistribution through a general tax-transfer from A, aiming at C, will end up at D through the disincentive effects, the redistribution through the inefficient move from A to B will also generate similar disincentive effects, moving us from B to E, which is Pareto inferior to D. Thus, the real choice is between A or moving to either D (through general redistribution) or to E (through the inefficient pursuit of equality in specific issues). The choice is clear, either we stay

at A, or if we want equality enough to be willing to pay the redistribution costs, we move to D by general redistribution. Never choose E by violating efficiency supremacy in specific issues.

It is true that an equality-improving measure need not be inefficient. However, under our proposed efficiency-supremacy in specific issues, such efficiency-consistent equality-improving measures will not be ruled out. Only measures that are inefficient are ruled out. In fact, all specific inefficient measures, whether equality-increasing, equality-decreasing, or equality-neutral, should be ruled out. An example of inefficient measure is the use of first-come-first-served in allocating scarce parking spaces in city central areas. Usually, it is pricing at very low levels, making first-come-first-served the effective allocation method, at least partially. The refusal to increase the prices to equate supply and demand results in excess demand with insufficient empty spots. Drivers seeking for empty spots have to waste too much time and petrol, not to speak of the resulting increased congestion and pollution. This inefficient measure achieves some equality at least in parking, as people with low incomes may also afford to park there. This equality effect is presumably the reason for the popularity of such measures. However, this perception is based on seeing only one area without a more overall view. The efficient solution is to increase parking fees to avoid excessive space hunting. This in itself may make the rich (who are willing to pay more for convenient parking spaces) better off and the poor worse off. However, if we also tax the rich more and help the poor more, all groups could be made better off. The same degree in equality in real income or utility could be achieved more efficiently.

Similarly, in judiciary decisions, at least for those affecting economic efficiency, the effects should not be weighted by incomes, such as counting a dollar to the poor as worth two dollars and a dollar to the rich as worth only half a dollar, as in fact proposed and done by some economists in cost-benefit analysis. Such systems of income or distributional weighting appear to be desirable in increasing social welfare, though they are counter to wealth maximization or efficiency. This

belief in the desirability of these systems is again based on seeing the direct effects without seeing the indirect effects. The policy of using distributional weights in cost-benefit analysis also makes earning higher incomes less valuable, increasing the disincentive effects. Instead of trying to pursue equality in specific issues, we should pursue equality generally, leaving the specific issues to be purely efficiency oriented. In principle, this is similar to the point that, to achieve equality, we should try to achieve a high degree of equality in total purchasing power, leaving the choice of how to spend the total incomes to the individuals. The objective of equality is achieved without the distortion of efficient individual choices or the violation of individual freedom of choice. For example, even if we want to achieve complete equality, it is better to equalize posttax/subsidy incomes across the board instead of allocating each and every good equally. Assuming perfect effectiveness (though unlikely in real life), both methods achieve perfect equality. However, the later inefficient policy would give Madonna and Kwang the same amount of lipsticks, but Kwang does not use lipsticks.

It is tempting for a particular judge or analyst to think, "I have no control on the distribution policy which I take as given, then for a particular decision/proposal, if I could promote equality somewhat at only a slight cost in efficiency, this should be a good thing." In fact, something similar probably had taken place for many decades, contributing to the inefficient pursuit of equality in many areas (such as the first-come-first-served system in car parking discussed above). Partly as a result, the total system was then perceived to be too low in terms of efficiency (including incentives) such that, starting from the 1970s, the degrees of progressivity in income taxation have been decreased several times in many countries. Combined with this reverse changes in progressivity, we end up with no more equality, but with many inefficient policies. We would have been better off without those inefficient equality-oriented policies in specific issues and kept the higher degrees in tax progressivity. Short-term good doings lead to long-run badness. Thus, Posner's advocacy of the separation of the judiciary and the legislature

and the related wealth maximization in the judiciary may largely be justified. For specific issues including judiciary decisions, efficiency supremacy irrespective of distribution (a "separation of distribution and efficiency" continuously challenged until now, e.g., Driesen and Malloy 2015, p. 5 of typescript) is acceptable, if supplemented by appropriate distribution in the general equality policy, as this will make all income groups better off.

Reconciling Rights with Welfare Maximization: Concluding Remarks

In the face of strong criticism, Posner (e.g., 1985, 2015) has retreated into pragmatism without giving up wealth maximization. While this provides some workable practicability, the conceptual justification and consistency are lacking. In particular, he seems to be confused and confusing in both accepting and rejecting both utilitarianism and individual rights at different places at the same time. The present entry provides both a justification and an explanation of Posner's position. Posner probably see some merits and problems in both utilitarianism/welfarism and rights but has not been able to reconcile them in a conceptually consistent way, hence, the apparently inconsistent positions. In addition to the previous section, this section tries to provide a consistent position that may lie at the back of Posner's head. At least this is the position I see as consistent and justifies wealth maximization for welfare maximization.

Since welfare is the only ultimate value (Ng 1990), the **ultimate** objective for a society should be social welfare – cannot be wealth, GDP, or any such similar objective things with no intrinsic value. Accepting welfarism and ignoring issues of animal welfare, social welfare is a positive function of individual welfares. Taking account of indirect and long-term effects, welfarism is consistent with the acceptance of certain rights, constitutional provisions, etc. if these may be justified on the ground of long-run welfare maximization. On any specific issue that a court, a government, or a policy adviser is making a

decision/suggestion, we are in a particular point in time with our given history, constitutions, statutory laws, legal precedences, accepted rights, moral principles, given endowments of individuals both in ability and inherited wealth, etc. Ideally, the previous decisions contributing to these “givens” should be based on welfare maximization, but few things in the real world can be ideal. The point here is that these “givens” determines the initial point A in Fig. 1 in the previous section. There, we show that, given any initial point such as A, when we are making a decision/suggestion on a specific issue, we should follow the principle of efficiency supremacy, treating a dollar as a dollar whomever it goes to. But this efficiency supremacy in specific issues (very close to if not exactly wealth maximization in Posner’s sense) should be supplemented by the equitable equality promotion policy in some branch of the government other than the judiciary.

Our position in using welfare maximization as the intrinsic, ultimate, and long-run moral position, but using wealth maximization (for welfare maximization) for specific issues in the short-run situations with many “givens,” may then explain Posner’s apparently conflicting positions under his “hybrid ethical system” (Posner 2015, p. 10) not only in a conceptually consistent way but provides a strong support for the efficiency (all groups better off) of wealth maximization for welfare maximization with equality supplementation. Our position that allows for feelings for justice and short-term “givens” also appears to be less extreme than that of Kaplow and Shavell (2002) who nevertheless provide a very powerful argument for basing policies “exclusively on their effects on individual’s well-being” (p. 465). I accept this at the ultimate level, but make some concessions in dealing with many “givens” in short-run decisions. These include the feelings of fairness, justice, etc. However, ultimately, these are important not intrinsically, but by affecting welfare or happiness directly or indirectly. Frustration from feelings of injustice already counts as negative welfare, and it may generate further negative welfare effects in the future through increasing social disharmony,

etc. Taking account of all these is consistent with welfare maximization. On the other hand, this entry goes further than this and accepts the use of wealth maximization in specific issues including judiciary decisions. However, in contrast to Posner, this is accepted under the qualification of appropriate supplementation in redistribution and as more clearly instrumental for welfare maximization.

Our acceptance of the many “givens” including the feelings of justice in the short run may be regarded as a form of pragmatism. However, since for the long run and intrinsically, we have a consistent guide of welfare maximization, our position is conceptually adequate and consistent. For example, we will not be in an awkward position for all those who believe in rights (or imperatives, including Kantian) for rights sake when faced with conflicting rights or when some rights may lead to disastrous outcomes in terms of welfare. This is so since no deontic, including Kant himself, believes in only one single right/imperative, and that welfare is not important. If one believes in only one single right, e.g., no murder under any circumstance and regards this as more important than any sacrifice in welfare, then he can be consistent. However, he may end up failing to save the whole world from going to hell when an escaped murderer carries out his hell creation plan. When we create/accept more rights/principles to constrain the excess or inadequacy of just one single right, we face the awkward position when two or more of our rights/principles are in conflict with each other. By using rights/principles for welfare maximization, we can provide a rational basis for accepting which rights (e.g., why human rights, animal rights, but no stone rights) and also on how to reconcile different rights when in conflict.

Of course, the effects on future welfare in the observation or violation of different rights by different degrees, or the welfare effects of social disharmony under different contexts, etc., are very difficult to guesstimate, not to say estimate. Nevertheless, these are matters of our lack of relevant information on which further studies may help to lower, not a matter of conceptual or moral philosophical acceptability.

Weber, Max

Dustin Garlitz

Department of Philosophy, University of South Florida, Tampa, FL, USA

Abstract

Max Weber (1864–1920) was a German jurist, political economist, and social scientist. This essay examines his intellectual background and academic career in economics and law, his place in the youngest German Historical School, his economic legacy, his work in economic and legal theory and economic and legal history, and his contributions to law and economics in his work *Economy and Society*, among his other notable publications. Focus is given to works of his that engage religion, in which he derives legal norms in a historical fashion. In regard to his contributions to economics, an emphasis is made on political economy, with his economic contributions presented in that context, as well as among a larger historical portrait.

Weber's Academic Career in Economics and Law

Throughout the course of his academic career, Max Weber's notable studies included works in law, legal history, economics, and economic history. Weber's father was a lawyer and a politician.

Weber pursued law and a legal education from the time he first matriculated at the University of Heidelberg in 1882. In his first semester at the University, he enrolled in a course entitled “Roman Law: Pandects and Institutes.” Weber then studied at the University of Strasbourg in 1883 and went on to the University of Berlin in 1884.

It was after earning his degree in law in 1886 that Weber sat for and passed the examination for Referendar, or took and passed the Bar exam, and commenced the practice of law. Weber then started work in the State Law and Agrarian History Faculty at the University of Berlin that year (Turner 2000: xv) and eventually pursued advanced legal studies there. In his legal studies at the University of Berlin, Weber had worked under the directorship of some of the leading representatives of the late nineteenth-century German legal academy. While continuing his legal studies at Berlin, Weber interned in the courts. Weber took a broad approach to his studying of law, which was common in his day. Accordingly, in addition to studying law, he spent time reading theology and philosophy, as well as a significant amount of history and political economy. As such, law and political economy had long been inextricably associated in the German cameralist tradition (Mommsen and Osterhammel 1987: 27).

When Weber became a doctoral student in 1888, he had also begun serving as a law clerk at the Royal District Court of Charlottenburg. His scholarship as a doctoral student bordered between legal and economic history, and he eventually publishing his doctoral dissertation on the history of medieval trading companies in 1889. Weber graduated *magna cum laude* that year with the full title of his dissertation published as “Development of the Principle of Joint Liability and the Separate Fund in the Public Trading Company from the Household and Trade Communities in the Italian Cities.” After Weber’s doctoral degree in law was conferred, he followed by serving as a junior barrister and then became an assistant judge or what was known as an *assessor*. As such, he had become a qualified lawyer in Berlin. After being drawn into legal practice, Weber first doubted his ability and potential to carry out

scholarly research in law. It was only after his chance of working as a syndic in Bremen – which he considered practical work – fell through that he decided to write a postdoctoral thesis, completing his *Habilitation* (Mommsen and Osterhammel 1987: 27). This second thesis was completed in 1891, which was titled *Roman Agrarian History and Its Importance for State and Civil Law*, and earned him the right to teach commercial, German, and Roman law.

Weber was awarded an extraordinary professorship in commercial and German law at the University of Berlin in 1892. After his brief stint at Berlin, Weber left the legal academy to take up a full professorship in political economy at the University of Freiburg in 1894, giving his inaugural academic lecture there titled “The National State and Economic Policy” in 1895. It has been argued that, in the former year, at the age of 30, Weber had lost interest in both the practice and the teaching of law, although he remained deeply committed to resolving basic questions about the nature and social functions of law as they appeared throughout the study of history. Weber went on to accept a chair in economics at the University of Heidelberg in 1896. In 1919, the year before his death, he moved to the University of Munich to take up a chair in economics.

Weber’s publication titled *Roscher and Knies: The Logical Problems of Historical Economics* (Weber 1975) was originally published in three parts in *Schmoller’s Jahrbuch für Gesetzgebung, Verwaltung und Volkswirtschaft*. The publication of Weber’s *Critique of Stammler* (Weber 1977) was essentially an extended review of Rudolf Stammler’s second edition of *The Historical Materialist Conception of Economy and Law: A Sociophilosophical Investigation*. Weber delivered lectures which were given to the public, under the title “Outlines of Universal Social and Economic History,” in the winter semester of 1919–1920, and which formed the publication that is titled *General Economic History* (Weber 2003). Weber’s most controversial work was *The Protestant Ethic and the Spirit of Capitalism* (Weber 2001), which he published in 1905. His magnum opus was his two-volume encyclopedia *Economy and Society* (Weber 2013), published

posthumously in the 1920s. It was in *Economy and Society* that Weber outlined many different types and forms of law and legislation and provided an explanation of the scope of economics and the economy in the framework of the emergent social sciences.

The Youngest German Historical School and Weber's Economic Legacy

Despite Weber's educational background in law, his professional career in academia was mainly spent in economics, in which he held two chairs. More precisely, it was his work in economic history that gave him the reputation as one of the leading figures of the youngest Historical School in Germany, along with Arthur Spiethoff and his frequent interlocutor Werner Sombart, the latter of whom he often held intellectual disagreements with while at times working on similar historical problems. Weber's concerns in economics broadened over the course of his academic career with his main focus eventually shifting to an area of scholarship that was to become known as economic sociology. Weber's concern within economic history – particularly as explicated in his work *The Protestant Ethic and the Spirit of Capitalism* – aligned well with the general climate of fin-de-siècle historical schools in Germany and in England. Weber, unlike others in the German School, spent very little time narrating the role played by economic policies of governments in economic change. Instead, like Sombart, Weber focused much more on the systematic study of modern capitalism, its nature, and the conditions for its emergence.

One of Weber's publications was devoted exclusively to the study of world economic history, the aforementioned *General Economic History*, which as stated previously was based on the transcripts of Weber's lectures in 1919–1920 and taken from his students' notes. The English edition was published in 1927 and was based upon the translation made by economic theorist Frank H. Knight, who spent most of his notable academic career at the University of Chicago. Knight taught a graduate seminar on Weber at Chicago in

the 1930s and wrote an article in 1928 on modern capitalism that dealt with Sombart as well as Weber, in which he sided with Weber. *General Economic History* was essentially an aggregate survey of economic development from ancient times to modernity. The text provided summaries, and in some case revisions, of important arguments that had been found in earlier writings, including succinct characterizations of the patterns of western economic development, as well as insightfully brief explanations of significant economic changes that were sometimes detailed in other writings (Turner 2000: 261).

Weber's Legal History

In his work *Ancient Judaism* (Weber 1967), Weber gave a treatment of the origins of the law, a problem that he and earlier legal scholars saw as occurring over the entire course of Old Testament studies. It has been argued that Weber's work in legal history was primarily a search for examples of laws and legal institutions that corresponded to the various "ideal types" which he attributed to the law (Turner 2000: 223–239). In other works, he compared Hindu law to Western ecclesiastical law, the German *Sachsenspiegel*, and Islamic and Judaic practices, and elsewhere, Islamic law to ancient Roman juristic practice. Weber classified the Canon Law of the Roman Catholic Church as sacred law and attributed its commitment to formal rationality partially to the relationship it had developed in late antiquity with the Roman law, and even more so, due to its transformation in the late eleventh century during the pontificate of Pope Gregory VII, at which time he found that the Church's functionaries were holders of rationally defined bureaucratic offices (Turner 2000: 223–239).

Weber's treatment of English common law adhered to the mainstream view of legal scholarship in his time in that he found modern English law was essentially a continuation of medieval English law. This led Weber to conclude that therefore it was not formally a rationalized type of law. And Weber gave treatments of many other substantial legal systems in the history of

civilization, as the case of his studies of the earliest of Roman law, formal canon law, Germanic law, Chinese law, and other Jewish, Hindu, and Buddhist laws. All of these legal histories figured prominently in different areas of Weber's legal scholarship (Turner 2000: 223–239).

Weber's *Economy and Society*: Economics

In *Economy and Society* (Weber 2013), Weber gives an explication of the economy and its arena of normative and de facto powers (Weber 2013: 311–635). This involves an explanation of the economy and social norms, the economic relationships of organized groups, and basic outlines of those groups. In Volume Two of the work (Weber 2013: 641–1363), Weber focuses on studying economic systems that reigned prior to the emergence of capitalism, such as feudalism (Weber 2013: 1070) and mercantilism (Weber 2013: 1097). At that point, he also pays attention to the basis and premise of economic enterprises, the economic and political power revealed in the study of ancient Germanic history (Weber 2013: 1256), and provides an attempt to outline an economic theory of antiquity (Weber 2013: 1266–1339).

In the first chapter of Part One (Weber 2013: 3), Weber discusses the frameworks of enterprise and formal organization, as well as voluntary and compulsory associations. Next, in the second chapter of Part One (Weber 2013: 63), he gives an analysis of the concept of economic action, a definition of the concept of utility, as well as an explication of the various modes of the economic organization of action (Weber 2013: 71), including typical measures of rational economic action and disparate types of economic organization. Weber continues by studying the media of exchange (Weber 2013: 75), means of payment, money, and the primary consequences of using money and credit and gives an analysis of its market, formal and substantive rationality of economic action (Weber 2013: 85), the rationality of monetary accounting, management and budgeting, the concept and types of profit-making,

and the role of capital (Weber 2013: 90). Also, he discusses the various kinds of calculations, such as substantive conditions of formal rationality in a money economy, market economies, and planned economies (Weber 2013: 109).

Weber's focus then shifts to the various types of economic division of labor (Weber 2013: 114), including types of the technical division of labor, social aspects of the division of labor (Weber 2013: 122), and the definition of occupation and occupational structure in such a context (Weber 2013: 140). Weber continues by studying production (Weber 2013: 150), from the appropriation of the material means of production to the appropriation of managerial functions and the expropriation of workers from the means of production. Followed is an analysis of various forms of communism (Weber 2013: 153), capital goods and capital accounting, the concept of trade and its principal forms (Weber 2013: 156), the condition of maximum formal rationality of capital accounting (Weber 2013: 161), and the principal modes of capitalistic orientation of profit-making (Weber 2013: 164). Weber then concludes by giving an outline of the monetary system of the modern state and the different kinds of money (including currency money) (Weber 2013: 166), restricted money, note money, the formal and substantive validity of money, and the methods and aims of monetary policy (Weber 2013: 180), followed by an excursus that involves the presentation of a critical note on the state theory of money, the nonmonetary significance of political bodies for economic order, the financing of political bodies (Weber 2013: 194), repercussions of public financing on private economic activity (Weber 2013: 199), the influence of economic factors on the formation of organizations, and a formal description of the mainspring of economic activity (Weber 2013: 202).

Weber's *Economy and Society*: Law

In the third chapter of Volume Two (Weber 2013: 941–952), Weber focuses on types of legal domination, including the basis of legitimacy, which he describes as domination and legitimacy. Weber

then outlines the three pure types of authority, first of which is legal authority, second traditional authority, and third charismatic authority (Weber 2013: 1111). In the description of the latter, Weber includes explanations of the routine character of charisma, its history in feudalism, as well as its transformation in a democratic direction. In the eighth chapter of Volume Two, titled “Economy and Law,” and which he labels “The Sociology of Law” (Weber 2013: 641), Weber discusses the fields of substantive law, which includes public law and private law, right-granting law and regulation, government and administration, as well as criminal law and private law, tort and crime, the limitation of power and separation of powers, substantive law and procedure, and the categories of legal thought (Weber 2013: 654). Later in the chapter (Weber 2013: 666), Weber focuses on the forms or creation of rights, including logical categories of legal propositions, which entails liberties and powers such as the freedom of contract, the development of freedom of contract, status contracts and purposive contracts which included the historical origin of the purposive contracts, institutions auxiliary to actionable contract (Weber 2013: 681) such as agency, assignment, negotiable instruments, limitations of freedom of contract, and extension of the effect of a contract beyond its parties and special law as conceived of as associational contacts including the notions of juristic personality, freedom, and coercion (Weber 2013: 729).

The next focus of Weber in the eighth chapter is on the emergence and creation of legal norms (Weber 2013: 753), including the emergence of new legal norms, entailing the presentation of theories of customary law insufficient as explanations, the role of party practices in the emergence and development of legal norms, and the process from irrational adjudication to the emergence of judge-making law (Weber 2013: 758), the development of new law through imposition from above and its approaches to legislation, and the role of the law prophets and of the folk justice of the Germanic assembly, as well as the primary role of law specialists (Weber 2013: 775). Weber then discusses legal honoraries and various

types of legal thought (Weber 2013: 784), including empirical legal training or law as craft; academic legal training, namely, law as a science; and its origins in sacred law, as well as the influence of Roman law (Weber 2013: 792). Weber continues by stressing formal and substantive rationalization as theocratic and secular law (Weber 2013: 809), namely, the general conditions of legal formalism; the substantive rationalization of sacred law; Indian, Chinese, and Persian law; as well as Islamic, Jewish, and Canon law, and then moves from there to explaining codifications (Weber 2013: 839), the driving forces behind the theory of codification, the reception of Roman law, and the development of modern legal logic, including the various types of patrimonial codification (Weber 2013: 856). Finally, Weber focuses on the formal qualities of revolutionary law (Weber 2013: 865), including natural law and the formal qualities of modern law, which entails an explication of revolutionary law and the French civil code in the natural law context, as well as expositions of natural law as the normative standard of positive law (Weber 2013: 866), explanations of the genesis of modern natural law, the transformation of formal into substantive natural law, class relations in natural law ideology (Weber 2013: 871), and the practical significance and disintegration of natural law and legal positivism in law as a vocation (Weber 2013: 875). In his discussion of the formal qualities of modern law (Weber 2013: 880), Weber gives an outline of particularism in modern law, the anti-formalistic tendencies of modern legal development, contemporary Anglo-American law, and lay justice and corporative tendencies in law as a vocation in modernity (Weber 2013: 892).

Weber's Economic and Legal Theory

Although trained in law, Weber did almost all his teaching in economics. He was first appointed to a chair of economics in Freiburg in 1894 and then became a successor to Karl Knies at Heidelberg in 1898. Weber's “Outline on Theoretical Economics,” or *Grundriss*,

consists, in its first part, mainly of thematic headlines and references. He expresses the aims and methods of theoretical economics there, citing the literature of Roscher, Hildebrand, Wagner, and Schmoller, but also of Menger, Sax, and Dietzel. Weber also wrote two pamphlets on Stock and Commodity Exchanges in 1984 and 1896 for the Göttingen Workers' Library, edited by Friedrich Naumann.

Weber was influenced by the legal theorist Georg Jellinek (Schluchter 1985: 83). There has been a significant amount of critical legal scholarship on Weber in relation to Rudolf Jhering, most notably expositions of their theories of action. Weber was a Heidelberg type philosophically and was a proponent of the Southwest German School of Neo-Kantianism, as was Jhering. Heinrich Rickert and Emil Lask were two of the leading figures of the school, and additional research has been conducted on Weber and Rickert among the cultural sciences and in a critical legal context, with Lask's 1905 work in legal philosophy complementing their intellectual thought. Weber's critique of Stammler was conducted in the context of Neo-Kantian legal philosophy. Additionally, legal scholarship that portrays Weber and Austrian legal theorist Hans Kelsen as Neo-Kantian is now emerging, although it is mostly focused on the nexus of law and politics in their works (especially its consequences for political and legal realism) rather than law and economics. In the tradition of the Southwest School of Neo-Kantianism, Weber attempted to theoretically position economics (as he did with law) within the cultural sciences. As his biographer Fritz Ringer has noted, Weber's long-term methodology involved the unification of the cultural sciences and social sciences (Ringer 1997), with law and economics at the core of these intellectual foundations.

► Impracticability

Whistle-Blower Policy

Sandeep Kapur¹ and Anthony Heyes²

¹Birkbeck College, University of London, London, UK

²University of Ottawa, Ottawa, Canada

Abstract

This chapter describes the increasingly important phenomenon of whistle-blowing and identifies the elements of optimal policy responses.

Whistle-blowers

Whistle-blowers are individuals who make public, or report to some external authority, the illegality, gross mismanagement, abuse of power, or other form of wrongdoing that they observe happening in or by an organization of which they are a part. It is usually also accepted that whistle-blowers are motivated by some notion of public interest rather than by personal pecuniary reward.

Whistle-blowers can be based in the private sector, in government departments, or in the “third sector.” Some definitions – for example, that adopted by the Government Accountability Project (GAP) in the United States – limit the category to current *employees* of an organization. High-profile examples of whistle-blowers include Ingvar Bratt (who exposed corrupt practice in the supply of weapons to India by Swedish engineering company Bofors AB), Sherron Watkins (who exposed accounting malpractice at Enron), and Edward Snowden (who made public the eavesdropping and intelligence gathering methods of the National Security Agency in the United States).

Whistle-blowing can serve an important role, both in discouraging wrongdoing in organizations in the first place and in facilitating the ending of such practice if it is already ongoing. Enforcement based on whistle-blowing has the advantage that the whistle-blowing agent – as an insider to the organization – sees things that an external enforcement agency typically cannot. He or she

may also be able to provide the external enforcement agency with the “hard evidence” that the agency needs in order to prosecute the miscreants – or tell the agency how and where to find it. Consider the following example:

On October 5, 2006, United States Coast Guard inspectors from Coast Guard Sector Portland boarded the ship at Vancouver, Washington to conduct a routine inspection. Inspectors reviewed the ship’s Oil Record Book, a document in which ship engineers must record all transfers and discharges of oil. Inspectors were unable to identify any discrepancies but were subsequently contacted by the ship’s Second Engineer who discretely told the inspectors about a flexible hose being used to bypass pollution prevention equipment and send oily sludge directly into the ocean. This prompted inspectors to conduct a second inspection on October 6, during which they located the hose and found additional evidence of its use. As a result of the prosecution the owners (Irika Maritime) were fined \$750,000 and placed on four year probation. The judge noted that the whistleblower should be protected from reprisal, but held no expectation of financial reward when contacting the inspectors. (United States Attorney’s Office 2007, p. 2)

Optimal policy response to whistle-blowing

What is the optimal policy to whistle-blowing? One aspect of policy relates to the personal treatment of whistle-blowers. As insiders, those who choose to blow the whistle are vulnerable to retaliation by their managers or by colleagues who are involved in, or complicit with, the wrongdoing. There is a long history – both anecdotal and academically documented – of whistle-blowers being subject to ostracism and other negative reprisal within their workplaces. There is evidence that the career prospects of employees who become whistle-blowers can be severely damaged by their actions, whether they stay with the firm that was the subject of their complaint or try to move to another organization (the employee can stigmatized by the label that they carry). This often carries over into financial stress, family breakdown, and adverse health impacts. Many organizations have evolved internal codes of practice to protect whistle-blowers from retaliation and other negative outcomes.

To some extent whistle-blowers may benefit from standard protections under employment or common law. But in recent decades most advanced countries have developed specific policies around whistle-blowing to enhance these protections. In the United Kingdom the Public Interest Disclosure Act (1999) and in the United States the Whistleblower Protection Act (1989) – strengthened by the subsequent US Whistleblower Protection Enhancement Act (2007) – provide overarching legal protection. In 2004 the Organisation for Economic Cooperation and Development (OECD) published its revised Principles of Corporate Governance to include whistle-blower protection (Organisation for Economic Cooperation and Development [OECD] 2004). In practice, these policies vary in their effectiveness.

In addition to policies aimed at protecting whistle-blowers from harm, we also observe specific efforts to encourage whistle-blowing. This includes the use of financial rewards or “bounties” for eliciting disclosure of information that can be used for successful prosecution for wrongdoing. The implementation of whistle-blowing “hotlines” – such as that established by the UK Financial Services Authority in 2008 for the reporting of financial fraud – aims to make the process of information disclosure easier. More recently in the United States, the Securities and Exchange Commission has set up a program that offers substantial financial reward for whistle-blowers whose disclosures lead to significant fines for financial misconduct.

The second aspect of whistle-blower policy relates not to how whistle-blowers themselves are treated but how the organization responds to their disclosures: whether such disclosures are always followed by investigation, and the severity of any penalties imposed on those found responsible for wrongdoing. Apart from the sheer cost of investigating every complaint, there are subtle informational constraints that affect the optimal policy design. Formal analysis of the regulatory design has been sparse. A substantial hurdle in setting up a microeconomic model is specifying the nonstandard motivations of whistle-blowers. To the extent they are motivated by some spirit of public interest – the gains from their intervention

are reaped by others – even as they typically bear significant personal costs, their action is difficult to rationalize in a conventional neoclassical economic model populated by self-interested actors (*Homo economicus*).

Theoretical approaches

Heyes and Kapur (2009) provide a *behavioral* economic model of whistle-blowing. Drawing on the well-established empirical literatures of whistle-blower motivations taken from social psychology, sociology, and related disciplines, they identify three sets of reasons why people choose to blow the whistle on wrongdoing in their workplace.

- (1) “Conscience cleansing”: the hypothesis is that employees have moral codes that preclude them from being complicit with – “going along with” or “keeping quiet about” – immoral activities proposed by or engaged in by their principals. Psychologists assert that being complicit with an immoral activity corrupts the self and “. . . whistleblowers disclose because they dread living with a corrupted ‘self’ more than they dread the other outcomes” (Alford 2001, p. 90). This was identified as the most common from the research available from other fields.
- (2) “Welfarism”: individuals obtain “warm glow” from improving welfare and engage in some sort of “cost-benefit” calculus in deciding when to blow the whistle, comparing external benefits of disclosure with its private cost. This is consistent with the notion of “justifiable disclosure” evidenced by Hunt (1997).
- (3) “Punishment motivation”: under this behavioral assumption employees disgruntled with their employer – perhaps for reasons unrelated to the wrongdoing in question – are motivated to hurt or do damage to the firm that employs them. Blowing the whistle on observed malpractice gives them an opportunity to do this.

Heyes and Kapur operationalize these diverse motivations and embed them in a principal-agent model with otherwise standard features. They use

the framework to assess the efficiency of a regulatory enforcement program based on tip-offs from whistle-blowers. They show that optimal policy is sensitive to the motivations attributed to the whistle-blower in any context. For instance, it is easy to see that policy must be more responsive to a “welfarist” whistle-blower than to the potentially frivolous disclosures of a disgruntled employee. Policy may also be sensitive to the fact that whistle-blowing norms vary across cultures (Patel 2003). Their model offers a general framework for analyzing how policy towards whistle-blowing should be tailored to the informational constraints faced by regulators and the complex motivations that lead whistle-blowers to act.

WTO: Procedural Rules

Yong-Shik Lee¹ and Alessandro Romano²

¹The Law and Development Institute, Decatur, GA, USA

²China-EU School of Law, China University of Political Science and Law, Beijing, China

Abstract

The Dispute Settlement Mechanism (DSM) of the World Trade Organization plays a crucial

role in resolving interstate trade disputes. This entry analyzes from a law and economics perspective some of the most important procedural rules of the DSM: (i) the standing, (ii) the allocation of litigation costs, and (iii) the existing remedies.

Introduction

Procedural rules are a set of rules prescribing the formal steps that must be taken in order to enforce legal rights. Because procedural rules define the mechanics of legal cases, they are a key component of any legal system. Unsurprisingly, law and economics has always paid a great deal of attention to procedural rules, yet most of the studies focus on private litigation. This entry examines and summarizes the findings of the relatively scant literature on the efficiency of procedural rules in interstate litigation, particularly the rules of dispute settlement under the World Trade Organization (WTO). There are two key reasons for investigating procedural rules within the WTO. First, the Dispute Settlement Mechanism (DSM) of the WTO is generally regarded as highly successful and is markedly different from the dispute settlement procedures adopted by other international institutions. Second, the DSM presents some features that are in clear contrast with the procedures adopted by national jurisdictions. Therefore, the standard litigation models developed to describe the incentives for litigating in national jurisdictions (e.g., Priest 1980) cannot properly explain the functionalities of the DSM. The most relevant differences are (i) the nature of the parties involved in the litigation, (ii) the allocation of litigation costs, and (iii) the existing remedies.

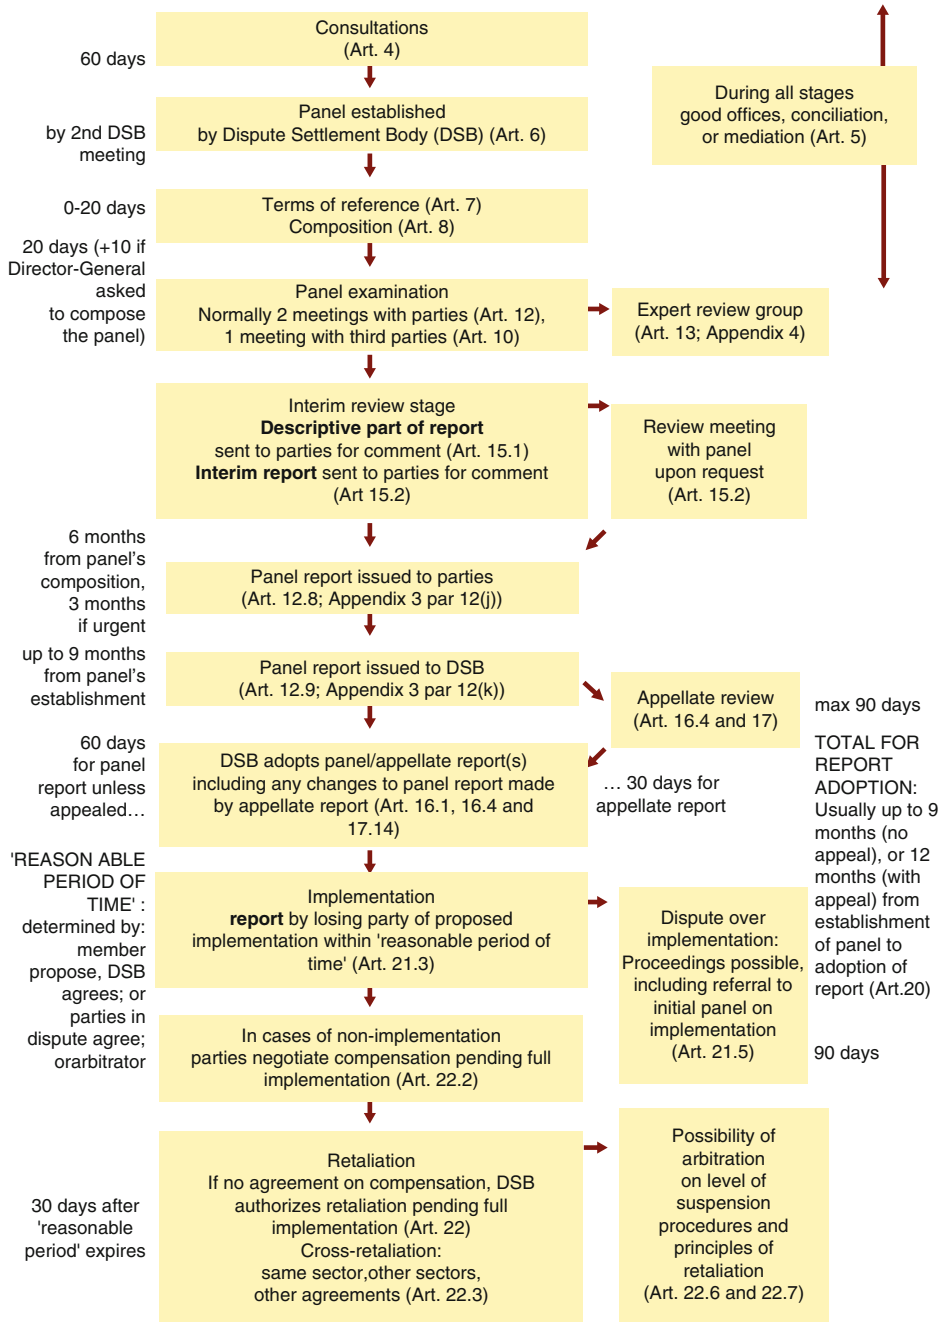

The WTO and Its Dispute Settlement System

The WTO is a result of the multilateral negotiations that took place between 1986 and 1994 (also known as the Uruguay Round). The primary objective of the WTO is to help trade flow as

freely as possible so long as there are no undesirable side effects because this is important for economic development and well-being (www.WTO.org). In other words, the main goal of the WTO is to eliminate, or at least reduce, barriers to trade among countries, including tariff and non-tariff barriers (NTBs). Tariffs are charges applied to goods in relation to the assessed value of the goods at customs, and NTBs are a wide range of regulations and policies that create significant costs for foreign firms in the import or export of products and services. To promote international trade through a rules-based system such as the WTO, it is essential to establish an effective system of dispute resolution. To serve this need, the DSM was created as a part of the WTO agreements (Annex 2 of the Agreement establishing the World Trade Organization). This dispute settlement system, generally considered the central pillar of the WTO, is embodied in the Understanding on Rules and Procedures Governing the Settlement of Disputes (hereinafter, Dispute Settlement Undertaking or DSU). The DSM can be invoked by member countries (members) when a member considers another member to have adopted a trade measure in violation of its obligations under GATT/WTO disciplines, leading to the impairment of any benefits accruing to it under the covered agreements (DSU Art. 3). Since its inception, the DSM has been frequently used to settle trade disputes among members, as demonstrated by the large number of cases, over 500, brought to the DSM between 1995 and 2016. When compared to the number of reports, only 101, adopted in the almost half-century of GATTs existence (Lee 2016), these figures show that members have relied on the WTO DSM much more than on its predecessor to resolve their trade-related disputes.

The WTO dispute settlement process is a highly legalized process, articulated in well-defined multiple phases (see Fig. 1). Its three main phases are described in the following:

1. Every dispute case must begin with a consultation phase for 60 days (DSU Arts. 4.5 and 4.7). The requirement of consultation is consistent with the goal of the DSM that is to settle

WTO: Procedural Rules, Fig. 1 Flow chart of the Dispute Settlement Process of the WTO (Source: www.wto.org, Reproduced with the permission of ©World Trade Organization (WTO) 2016)

disputes rather than making formal rulings (World Trade Organization 2001). The vast majority of cases are settled in the consultation process; as of October 2014, only 156 out of

486 dispute settlement cases had advanced to the panel stage (Lee 2016).

2. The complainant may request the establishment of a panel if the dispute has not been

resolved at the consultation stage. Panels are quasi-judicial bodies that adjudicate disputes arising between members. Panels are created on an ad hoc basis and are composed by either three or five experts detached from any government (DSU Arts. 8.1 and 8.2). As a general rule, the panel issues its report and circulates it publicly 6 months after its composition (DSU Art. 12.8).

3. Both the complainant and the respondent may appeal the panel decision to the Appellate Body (AB). The AB is a permanent body within the WTO DSB composed by seven members. The role of the AB is to review the legal aspects of panel reports and examine the consistency of panel decisions with relevant GATT/WTO rules (DSU Art. 3.2).

The Law and Economics of Procedural Rules

The WTO dispute settlement process is distinctively different from national jurisdictions in three aspects: the standing of parties, the allocation of litigation costs, and the remedies. These differences are further explained below.

Standing: Public Enforcement in the WTO

The DSM does not allow litigation by private parties; only members have standing to bring complaints before the DSB (DSU Art. 10.2). Thus, the WTO has adopted a mechanism of public enforcement (i.e., the parties of an international agreement – in this case the members – have the exclusive standing to litigate in the dispute settlement body) (Sykes 2005). In contrast, most domestic legal systems and many other international fora rely on private enforcement, in which private parties litigate against wrongdoers. For example, virtually all the cases litigated in the International Centre for Settlement of Investment Disputes (ICSID) are initiated by private parties (Choi 2007). Law and economics literature has attempted to explain why the WTO adopted public enforcement. According to Sykes (2005), governments of importing countries have no incentive to allow private parties standing on trade-related

issues and invite challenges to their trade measures by them.

The public enforcement scheme creates an interesting dynamism with respect to private interest groups. Under a private enforcement mechanism, private parties can decide when to litigate a case and base this decision on their own cost-benefit calculation (Priest 1980). In contrast, in the WTO, the firms that are being harmed by a restrictive trade measure have to persuade the government to litigate the case (Luanratana and Romano 2014). However, private parties do not have equal influence over the government (Tullock et al. 2002); strong and concentrated interest groups may influence the government to engage in litigation when it is not in the public interest (Shaffer 2003). On the contrary, small firms operating in fragmented markets may not have sufficient leverage to convince the government to litigate their case, even when litigation would be efficient and in the public interest (Romano et al. 2015). Small firms affected by a restrictive trade measure may not be able to deliver an organized, united voice to the government. This is a collective action problem; free riding and coordination problems prevent small firms from joining forces to influence the government, even if it would be in their best interest to do so (Olson 1965). An additional concern associated with a system of public enforcement is that governments might be reluctant to engage in a dispute due to diplomatic considerations (Davis and Shirato 2007). For example, Japan has not been actively bringing complaints against China, because the latter is Japan's largest export market (Davis and Shirato 2007).

Litigation Costs

The allocation of litigation costs is widely recognized by law and economics scholars as an important determinant of the number and kind of disputes litigated. The underlying rationale is that a rational actor will decide to litigate when the expected benefits from the litigation outweigh its cost (Priest 1980). For example, let us assume that the benefits (B) of winning the case are equal

to 150, the cost of litigation (C) is 100, and the probability of winning the case (P) is 0.5 (for the sake of simplicity, we do not consider the possibility of a settlement). In this case, the plaintiff has no incentive to litigate because the cost of litigation is higher than the expected benefits, or $C > P * B$. Although this view only offers a very stylized description of litigation, it holds some descriptive power in the context of private litigation. By comparison, the WTO presents an additional layer of complexity due to the exclusive standing of the government in the litigation, as well as the absence of any rule requiring firms affected by a trade measure to contribute toward the cost. While there are cases in which firms contribute to the cost of litigation, particularly in developed countries, it is not a general practice. The incentives of private parties and the government can be summarized as follows (Luanratana and Romano 2014):

1. Firms do not internalize the actual cost of litigation. Instead, they consider the share of the costs that they agree to cover (which can be anything ranging from 0 to the full cost of litigation) plus the cost of lobbying the government. This sum is not necessarily equal to the litigation costs, and it can even be higher if there is special resistance on the side of government. In the cited example, let us assume that firms only bear half the litigation costs and that lobbying has a cost of 10. Then the litigation has a positive payoff for the firm because the expected benefits are still greater than the cost ($50 + 10 < 150 * 0.5$).
2. Governments look at the cost of litigation minus the quota borne by the firm and the political costs minus the political benefits of litigating the case.

Therefore, the incentives of the government and the firms cannot be captured by the standard model of private litigation. It is the interplay between the incentives of these two agents, the government and the firms, that determines which cases are brought to the DSB. While there is no evidence that the interplay of the incentives of firms and governments leads to an efficient

selection of cases, data strongly suggest that complainants only start litigation when they have a high likelihood of succeeding. In fact, complainants prevail in around 90% of all cases (Guzman 2002; Hoekman et al. 2009; Keisuke 2003), compared to about 50% in the ICSID (Turk 2011), suggesting that strong cases are selected and brought before the DSB. The literature has not agreed on a single explanation for the observed pattern (e.g., Colares 2009; Guzman 2002).

Remedies

Remedies have been the subject of extensive discussion in the context of compliance with DSB decisions (Bronckers and Van den Broek 2005). Generally, an AB or panel decision does not entail monetary compensation (see, e.g., Mavroidis 2000) but requires the infringing member to remove the noncomplying measure (DSU Art. 19) within a reasonable amount of time (DSU Art. 12.3). Therefore, unlike cases in private litigation, the DSM does not aim to compensate the complainant for the infringement but to prevent continuing rule violations by ensuring withdrawal or modification of measures that are inconsistent with WTO agreements (DSU, Art. 3.7). If the infringing member does not withdraw or modify the measure within a reasonable amount of time, the complainant has the right to retaliate (DSU Art. 22.2) by suspending or withdrawing trade concessions in the form of raising customs duties and other nontariff barriers.

Law and economics scholars have raised concerns about the efficiency of the existing remedies, because the absence of monetary compensation might negatively affect deterrence. Optimal deterrence is achieved only when the injurer (the infringing member) internalizes the harm by compensating the victim (the complainant) for the entire harm caused (Shavell 2009). If no monetary compensation is to be awarded, then the decision on the introduction of a restriction to trade (trade measure) will largely be based on a political calculus, such as the possibility of drawing domestic support for introducing a trade measure that benefits its constituency or political ramifications in

international relations. There is no reason to assume that these political considerations systematically lead to an efficient outcome.

Moreover, retaliation seems to be a poor surrogate for compensation due to a number of reasons. First, retaliation is not always a possibility, particularly for small developing countries that cannot realistically impact the trade of the infringing country (Bronckers and Van den Broek 2005). Second, retaliation may affect the trade of the retaliating country more adversely than that of the infringing member (Bronckers and Baetens 2013). Third, retaliation generally targets sectors of the economy of the infringing country not related to the trade measure (Bronckers and Van den Broek 2005). For instance, as a retaliation against the EU for its decision not to comply with the DSB ruling on its banana regime, the United States restricted the import of Italian batteries (*European Communities Regime for the Importation, Sale and Distribution of Bananas*). Some scholars have argued that retaliation can be effective if the interest group affected by retaliation (Italian battery producers) effectively lobbies the government to lift the restrictive measure in order to end the retaliation (Nzelibe 2005). It is ultimately an empirical question whether exporting interest groups will mobilize frequently enough and can effectively induce their government to comply with the DSB decision. Lastly, retaliation is in and of itself a restriction to trade and hence runs counter to the goals of the WTO (Bronckers and Van den Broek 2005).

Future Research

There are two main paths of law and economics research, analytical (descriptive or positive) and normative. The former addresses the existing rules and institutions and their effects, whereas the latter explains their possible modification in order to achieve a given goal (Coleman 1980; Lee 2014, 2016). It is not straightforward to anticipate the directions in which these two paths of research will proceed in the domain of international trade law in general, as well as in the study of the WTO in particular.

There is an active debate as to whether the existing procedural rules are penalizing developing countries. In fact, a large number of developing countries, particularly least-developed ones, have not used the DSM (Bown and Hoekman 2005). Possible reasons for the underrepresentation of developing countries might be their political and economic weakness vis – vis more powerful trading partners, their lack of the expertise in litigating cases, and the high costs associated with litigating a case in the WTO system (Davis and Bermeo 2009). Understanding to what extent developing countries are disadvantaged by the status quo can fuel normative analyses aimed at identifying ways to facilitate their participation in the DSM. From this perspective, scholars have started to emphasize the role that many actors, including law schools and nongovernmental organizations, can play (Bown and Hoekman 2005). A fundamental guiding principle of normative research in this domain ought to be realism. Any change in the WTO requires the consensus of 164 members; therefore, radical changes to the status quo in the DSM are unlikely to take place in a near future (Grewal 2008).
